GUIDE TO GARDEN PLANTS

A PRACTICAL GUIDE TO GARDEN PLANTS

CONTAINING DESCRIPTIONS OF THE

HARDEST AND MOST BEAUTIFUL ANNUALS AND BIENNIALS

HARDY HERBACEOUS AND BULBOUS PERENNIALS

HARDY WATER AND BOG PLANTS

FLOWERING AND ORNAMENTAL TREES AND SHRUBS

· CONIFERS; HARDY FERNS; HARDY BAMBOOS

AND OTHER ORNAMENTAL GRASSES

ALSO THE BEST KINDS OF

FRUITS AND VEGETABLES

THAT MAY BE GROWN IN THE OPEN AIR IN THE BRITISH ISLANDS

WITH FULL AND PRACTICAL INSTRUCTIONS AS TO

CULTURE AND PROPAGATION

By JOHN WEATHERS, F.R.H.S.

LATE ASSISTANT-SECRETARY TO THE ROYAL HORTICULTURAL SOCIETY,
HORTICULTURAL LECTURER TO THE MIDDLESEX COUNTY COUNCIL,
FORMERLY OF THE ROYAL GARDENS, KEW, ETC.

'Then let the learnèd gardener mark with care
The kinds of stocks, and what those kinds will bear;
Explore the nature of each several tree,
And, known, improve with artful industry.
And let no spot of idle earth be found,
But cultivate the genius of the ground'—VIRGIL (*Dryden's translation*)

NEW YORK AND BOMBAY

1901

P R E F A C E

IN adding a ' PRACTICAL GUIDE TO GARDEN PLANTS ' to the literature of Gardening my chief aim has been to produce a book that will be unique and of real use not only to Amateur Gardeners, for whom it is particularly intended, but also to those engaged professionally in Horticulture. The work is the result of many years' experience among all kinds of Plants, gained in various nurseries and gardens in this country and on the Continent under many different conditions. It deals thoroughly with the description, cultivation, and propagation of all plants—Flowers, Fruits, and Vegetables—that may be grown more or less successfully in the open air in the British Islands, and it cannot be regarded in any sense as a botanical treatise or text-book. Tender plants which require the protection and artificial warmth of green-houses have been excluded, with the exception of a few that may be grown in the open air during the summer months. Due regard has been given to the different climatic conditions prevailing throughout the British Islands, and the reader is advised as to whether any particular plant will flourish out of doors in all parts of the Kingdom, or only in a few favoured spots like Devonshire, Cornwall, and the South of Ireland.

ARRANGEMENT

The work has been divided into Four Parts for the sake of convenience. In Part I. the Life History of Plants from start to finish is dealt with in such a way, and without the use of technical expressions, so as to give the reader a good idea of the work carried on by the roots, stems, leaves, flowers, fruits &c. of plants in general.

The Propagation of Plants by means of Seeds, Cuttings, Budding, Grafting, Layering &c. is also discussed from a general point of view, so that the reader may be better able to grasp the details given later

on under each particular genus and species. The various kinds of Soils, Manures, and Plant-foods have also received a good deal of notice, chiefly because the importance of such subjects is as a rule not fully grasped by amateurs. Intimately connected with Soils and Manures are the various operations for the improvement of the soil, such as Digging, Trenching, Hoeing, Raking, Mulching, Drainage &c., all of which are explained to the reader. The management of Lawns and Pathways is also dealt with in this portion of the work.

Part II. is devoted entirely to the Flower Garden, that is to say, to the Description, Culture, and Propagation of all the most beautiful HARDY ANNUALS and BIENNIALS; HARDY HERBACEOUS PERENNIALS; BULBOUS PLANTS; ROCK GARDEN PLANTS; HARDY WATER and BOG PLANTS; ORNAMENTAL and FLOWERING TREES and SHRUBS, including CONIFERS; HARDY BAMBOOS, and other ornamental GRASSES; besides HARDY FERNS, HORSETAILS, CLUBMOSES &c.

This important part of the work includes almost everything worthy of a place in the garden. As many as 133 Natural Orders, containing over 1000 Genera and several thousand Species, have been described and fully dealt with in regard to Culture and Propagation in every case.

The plants have been arranged on a systematic basis, and that laid down by Bentham and Hooker in their standard work, the 'Genera Plantarum,' has been followed in the main. The natural orders, beginning with the Crowfoot Order (*Ranunculaceæ*), and ending with the Clubmosses (*Lycopodiaceæ*), follow each other according to their natural relationship, and the genera in each order are arranged in the same way. The species belonging to each genus, however, follow each other in alphabetical order for the sake of convenient reference.

The value of arranging all the flowering plants thus in their natural groups is fully discussed at p. 120 under the article on the 'Classification of Plants,' and need not be further referred to in this place, except to say that it is hoped the arrangement on such a basis will at once commend itself to every reader interested not only in growing plants, but also in studying them, and comparing their characteristics one with another. So that the reader may be able to see at a glance some of the choicest plants belonging to the various groups referred to above, a careful selection has been made from each of them. Thus there will be no difficulty in choosing any Annuals or Biennials, Hardy Herbaceous Perennials, Flowering Trees and Shrubs &c. one may wish to cultivate in his or her garden.

As colour plays a very important part in artistic gardening nowadays, lists are also given of Hardy Plants, having flowers of white, red, blue, yellow, purple, and other shades. These lists will be valuable for

the purposes of massing in herbaceous borders to produce effect by means of contrast in floral colouring. As the height is given to almost every plant described it is scarcely necessary to make out a list of plants with various heights.

Under the 'Trees and Shrubs' at p. 107 the list has been so arranged as to enable the reader to see immediately which kinds are in blossom at any particular month of the year, from January to December.

Part III. is devoted to the Description, Culture, and Propagation of the best Hardy Fruits for our climate, and Part IV. is in the same way devoted to Vegetables. The Culture plays an important part in these two groups, and is fully described in simple language. The methods recommended are not those of any particular gardener, but such as are generally practised in the best gardens in the kingdom. Sometimes more than one way of growing a plant is mentioned, but the reader should always remember that while the principles of cultivation are usually the same, there may be many differences in detail. He should, therefore, use a wise discretion, by taking into consideration the nature of the soil, situation, aspect, altitude &c. of his own particular garden, and then by means of the information given, mixed with a little common sense (one of the best plant foods known), there will be little difficulty as a rule in growing his plants, flowers, fruits, or vegetables. As a reminder of the various operations to be performed during the year, a short calendar of work has been added to the Flower, Fruit, and Vegetable sections of the book.

THE GLOSSARY

Although it is always a difficult task for a technical writer to describe the objects and operations connected with his own profession in ordinary language, I have endeavoured to avoid as far as possible the use of all technical gardening and botanical expressions throughout the work, except where such were inevitable. Simple language has been used throughout, but technical words are to be found here and there in the descriptions of the various natural orders and genera. These terms, however, are comparatively few, and occur many times over under similar circumstances, so that the reader will soon regard them as ordinary language. With a view, however, of making their meanings quite clear, all technical expressions have been grouped together in a 'Glossary,' and numerous thumbnail sketches have also been given to further elucidate the meanings of many.

PLANT NAMES

One of the greatest complaints amateurs have against gardeners and botanists is that they *will* use 'such long Latin names' for their plants. And there are some even—very few it is to be hoped—who use this as an argument, not only against the study, but also the cultivation of beautiful plants. 'If you would only give your plants English names,' they say, 'we could understand them better and take more interest in them.' This may be very true, but such people seldom find difficulty with names like Begonia, Gloxinia, Campanula, Passiflora, Colchicum, Crocus, Primula, Geranium, Pelargonium, Zinnia, Phlox, Coreopsis, Nemophila, and many other botanical names which practice has rendered familiar. As a matter of fact it is simply impossible to give every plant an English name, and efforts to do so have resulted in some very peculiar if not really awkward and inappropriate appellations, which are often worse than the proper botanical name. There is no need to say anything against the use of proper English names for plants in all cases where they can be appropriately used and are generally accepted. Such English names are a help to the amateur, and throughout this work they have been used on every possible occasion, even to the extent of adopting popular names such as Buttercup, Poppy, Daisy &c. to represent the various natural orders to which they belong. No attempt, however, has been made to coin new or awkward popular names; and it must be pointed out that one and the same English name is often applied to two or more plants belonging to totally different families, as may be seen by reference to the copious INDEX at the end. The scientific names adopted throughout the work are those generally accepted by botanists throughout the world.

ILLUSTRATIONS

The illustration of species has not been attempted, as a satisfactory representation of each one would have necessarily increased the bulk of the book and its cost to the purchaser beyond what is thought desirable, and anything short of this would be of little practical value. As faithful a word-picture of a plant as possible has been given in the descriptions, and it is hoped that this will be of real practical value to the reader, and enable him to recognise any particular plant. Illustrations, however, have not been altogether abandoned. The 'Glossary of Technical Terms' at the beginning of the book has

been freely illustrated, as have also such operations as Budding (p. 58), Grafting (p. 52), Layering (p. 59), Pruning (p. 1033), Tree-planting (p. 1032) &c. The differences between the branches bearing flower-buds and leaf-buds in most of the fruit trees have also been illustrated for the benefit of those amateurs who like to do their own pruning but are often not quite sure as to whether they are cutting away fruit-bearing branches or not.

Such, in brief, is an outline of the work ; and I may add in conclusion that I am indebted for many hints and suggestions to numerous friends, among whom special mention may be made of Mr. JAMES BRITTEN, F.L.S., of the Botanical Department, British Museum ; Mr. GEO. NICHOLSON, F.L.S. ; Mr. W. WATSON, and Mr. W. J. BEAN, of the Royal Gardens, Kew ; Mr. GEO. TEBBUTT, of Mogden Gardens, Isleworth ; and Mr. W. H. DIVERS, Head Gardener to the Duke of Rutland, Belvoir Castle, who has kindly read the proofs of the Fruit and Vegetable portions of the work, and whose assistance may be regarded as an extra guarantee of accuracy and sound practical advice.

GLOSSARY

OF THE PRINCIPAL TECHNICAL TERMS USED SPARINGLY IN THIS WORK

LIKE every other profession, Gardening has its own peculiar terms and expressions, which are readily understood by the skilled practitioner. To the amateur, however, such technical terms and expressions are often bewildering when not explained in simple language or without illustration. To meet this difficulty, and to encourage the amateur to take a keener interest in the plants he may have in his garden, the technical terms used in this work are explained in the following glossary. In all cases where there is likely to be some doubt as to the meaning, an illustration has been given. It must, however, be understood that as regards form, it may often be necessary to use two or more terms to convey an accurate idea. Thus a leaf may be called 'ovate-lance-shaped' which means that its shape is somewhat between ovate and lance-shaped—it is broader than lanceolate (fig. 68) and narrower than ovate (fig. 75). And so on with other expressions. As a rule the mere botanical expressions have been avoided as far as possible in the body of the work, wherever a suitable English one could be substituted without inaccuracy.'

Abortive, Abortion, imperfectly formed or rudimentary, as is often the case of stamens and petals.

Acanthus, spiny.

Acaulescent, Acaulis, apparently stemless, as in Primroses and other plants where the spaces between the joints are very short.

Accrescent, growing after flowering is over, as with the calyx of *Physalis Francheti* (p. 691).

Accumbent, lying against a thing, applied to the seed leaves or cotyledons in the seed.

Acerous, needle-shaped, as the leaves of Pines, &c. (see **Acicular**).

Achene, Achenium, a hard dry one-seeded superior fruit, as in Buttercup, Clematis, Strawberry. In fig. 1 the left hand drawing shows a magnified achene of a Buttercup with a section of the ovary, within which

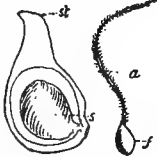

FIG. 1.—ACHENE.

the seed s appears. The stigma is shown at *st*. The right-hand drawing shows a feathery achene of Clematis. The fruit is at *f*, and the awn at *a*.

Achlamydeous, flowers without sepals or petals, as with most of the plants described from p. 759 to p. 805.

Acicular, needle-shaped, as in the case of Pine leaves (fig. 2).

Acinaciform, scimitar-shaped, like leaves of some Mesembryanthemums.

Acrogenous, growing from the apex, as in the case of Ferns.

Aculeate, armed with prickles, as the stems of Roses, Brambles &c. (fig. 3).

Acuminate, drawn out into a long point; taper-pointed (fig. 4).

Acute, sharp; forming an angle less than a right angle at the tip.

Adelphia, a brotherhood. Stamens are

FIG. 2.—ACICULAR.

monadelphous,' as in the Mallows (p. 270), diadelphous,' as in the Labiate family

FIG. 3.—ACULEATUS. FIG. 4.—ACUMINATE.

(p. 742), or 'polyadelphous,' as in the Hypericums (p. 265); according as they are arranged in one, two, or more fascicles or bundles.

Adnate, one organ united to another, as an ovary to the calyx-tube, or stamens to petals.

Adpressed, pressed close to anything, but not united with it, like the hairs on stems and leaves.

Adventitious, accidental, out of the usual place. Roots are said to be 'adventitious' when developed from any part of a plant except the 'radicle' or first downward growth from the seed.

Æruginous, verdigris coloured.

Æstivalis, produced in summer.

Æstivation, the arrangement of the parts of a flower (i.e. sepals, petals, stamens, pistils &c.) when in bud. The term 'præ-floration' is used in America.

Agrestis, growing in fields.

Alabastrum, a flower-bud.

Alæ, the wings or side petals of a papilionaceous flower, represented in fig. 5 at *w*.

Alate, alatus, winged, as the stems of Thistles and various seeds—e.g. that of the Elm.

Albescens, albescent, turning white, or whitish.

Albumen, nutritious matter contained in the seed to feed the young plant until it has developed roots and leaves (see p. 25).

Albumum, the sap-wood, or outer rings of wood in dicotyledonous trees.

Albus, white.

Alliaceous, with a Garlic or Onion-like odour.

Alpestris, sub-alpine.

Alpine, a term applied to plants native of high mountains, beyond the forest range.

Alternate, leaves arranged on the stem one after another (fig. 6). Petals are alternate with the sepals, or the stamens with the petals, when they stand over the spaces between them.

Alveolate, honey-combed like; with hollows or depressions in regular order, as on the bare flower heads or receptacles of many of the Compositæ (p. 492).

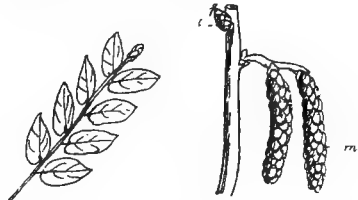

FIG. 6.—ALTERNATE. FIG. 7.—AMENTUM.

Amentaceous, a term applied to plants having the flowers in catkins, like the Willow and Hazel (fig. 7). A female flower is shown at *f*, and the male ones at *m*.

Amplexicaul, said of leaves when clasping the stem with the base (fig. 8).

Ampullaceous, swelling out like a bottle or bladder.

Anastomosing, forming a network, as the veins of leaves and fronds.

Ancipital, two-edged, as in the flower-stems of many Iridaceous plants.

Androecium, the male organs or stamens of a flower collectively (figs. 9, 55, 56, and 109).

Anemophilous, wind-loving—said of wind-fertilised flowers, like Willows, Conifers &c., the pollen of which is blown about by the wind and is thus carried to the stigmatic surface of the carpels in the female flowers.

Anfractuose, bent hither and thither.

Angios, covered, hidden. **Angiospermous**, having the seed enclosed in an ovary (p. 121).

Anisos, unequal. **Anisomerous**, parts unequal in number in the same flower.

Annual, flowering and fruiting the first season of being raised from seed, and of one year or season's duration only (p. 78).

Annulus, the name given to the ring of tissue around the upper portion of the stalk in Mushrooms and other Fungi. Also applied to the row of strong cells in spore cases of Ferns.

Anther, the essential part of the stamen which contains the pollen. In fig. 9 the anther is shown by the letter *a*.

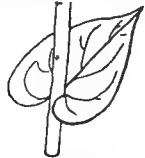

FIG. 8.— AMPLEXICAUL

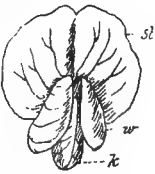

FIG. 5.—ALÆ.

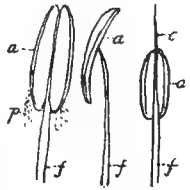

FIG. 9.—ANTHERS.

Antheridium, the organ in Ferns corresponding to the stamens in flowers (p. 1009).

Apetalous, without petals, as with *Ancmones*, *Clematis* &c.

Apex, the end furthest from the point of attachment, as in the case of leaves.

Aphyllous, leafless, like the stems of many exotic *Euphorbias* and *Cactaceous* plants.

Apiculate, having a very small hard point at the end or apex of a leaf, as in fig. 10.

FIG. 10.—**APICULATE.**

Apocarpous, when several pistils or carpels in the same flower are separate, as in the *Strawberry* and many *Ranunculaceæ*.

Apterous, without wings.

Aquatic, **aquatilis**, living or growing in water.

Arachnoid, cobwebby, like some of the *Houseleeks* (p. 44).

Arboreal, **arborescent**, growing into a tree.

Archegonium, the organ in Ferns corresponding to the carpels or pistils in flowers (p. 1009).

Arcuate, curved like a bow.

Arenarius, **arenose**, growing in sandy soil.

Argentus, silvery.

Argillose, **argillaceous**, growing in clayey soil.

Argos, Greek for silvery white—as in *argophyllus*, white-leaved.

Argutus, very sharply toothed.

Arillate, seeds furnished with an aril or fleshy growth from the base, as in the *Yew*, *Euonymus* &c. (fig. 11). At *a* is represented the fleshy aril, and at *f* the fruit or seed.

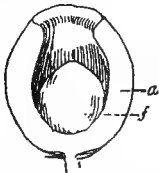

FIG. 11.—**ARILL.**

FIG. 12.—**ARISTATE.**

Aristate, awned or bearded, like *Barley* (fig. 12).

Articulatus, jointed.

Arvensis, growing in cultivated grounds.

Ascending, curving upwards into a vertical, from a more or less horizontal or prostrate position.

Asper, **asperous**, rough; furnished with harsh hairs.

Assimilation, the process of manufacturing food by the leaves (see p. 34).

Ater, deep black; used in combinations such as *atropurpureus*, *atrococcineus*, *atrosanguineus* &c.

Atratus, becoming black.

Attenuate, narrowing gradually to a point.

Aurantiacus, orange-coloured.

Auratus, golden-yellow.

Aureus, golden.

Auriculate, **Auricled**, having *auricles*, or ear-like appendages at the base of the leaves (fig. 13).

Awn, a long-pointed bristle-like appendage, as the beard of many kinds of grasses, like *Barley*, *Oats* &c.

Axil, the upper angle formed by the union of the stem and leaf.

Axile, proceeding from the centre or axis. This term is used in connection with the way seeds are arranged on the placentas in the ovary shown at *a* in fig. 86.

Axillary, produced in the axils of the leaves or other organs.

Axis, the main ascending stem and descending root of a plant.

Azureus, sky-blue.

FIG. 13.—**AURICULATE.**

Baccate, having a more or less succulent or pulpy seed-vessel or berry as in the *Fuchsia*, *Aucuba*, &c.

Barbatus, bearded, having tufts of soft hair.

Bearded, having long hair like a beard, as the 'crests' of many *Iris*s (p. 917).

Berry, a pulpy fruit containing several seeds imbedded in the juice, as the *Currant*, *Gooseberry*, *Orange* &c. (fig. 14).

FIG. 14.—**BERRY.**

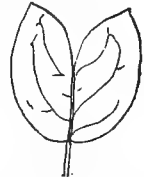

FIG. 15.—**BIFID.**

Bifid, divided half-way down into two parts (fig. 15).

Bijugate, having only two pairs of leaflets, as shown in fig. 16.

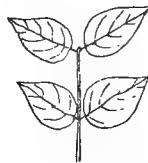

FIG. 16.—**BIJUGATE.**

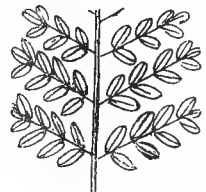

FIG. 17.—**BIPINNATE.**

Bipartite, divided nearly to its base into two parts; nearly the same as **Bifid**.

Bipinnate, when the pinnae or divisions of a pinnate leaf are themselves again pinnate, as shown in fig. 17.

Bipinnatifid, when the divisions of a pinnatifid leaf are themselves pinnatifid (fig. 18).

FIG. 18.—BIPPINATIFID.

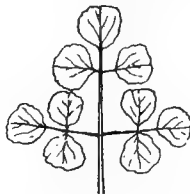

FIG. 19.—BITERNATE.

Biternate, when the divisions of a ternate leaf are themselves ternate (fig. 19).

Blade, the lamina or flat part of a leaf (fig. 98, b).

Bracteatus, furnished with bracts.

Bracteoles, minute bracts attached to the base of the pedicels.

Bracts, small leaves somewhat different from the others, seated on the flower stalks (peduncles) (fig. 89, b).

Bulb, a leaf-bud with fleshy scales, usually placed underground. In fig. 20 *a* represents the scaly bulb of a Lily, and *b* the tunicated bulb of a Tulip.

Bulbiferous, bearing bulbs.

FIG. 20.—BULBS.

FIG. 21.—BULBILS.

Bulbils, small bulbs, produced in the axils of the leaves of many Lilies (fig. 21, b).

Bulbous, having bulb-like stems or roots.

Bullate, blistered or puffed up, like the leaves of Savoys.

Caducous, dropping off, as the petals of Poppies.

Cæruleus, pale blue.

Cæsius, ash-grey.

Cæspitose, in close dwarf tufts, like many Dianthus (p. 238).

Calcarate, furnished with a spur, like the flowers of Larkspurs, Columbines, Tropæolums &c. (fig. 22).

Calcælate or **Calciform**, having a pouch or slipper, as in Calceolaria and the Lady's Slipper Orchid (fig. 23).

Calyx (Sepals), the outer and usually greenish whorl of leaf-like organs of the flower below

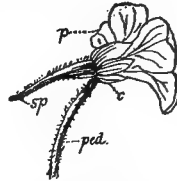

FIG. 22.—CALCARATE.

FIG. 23.—CALCÆLATE.

the corolla (petals). The calyx is shown at *c*, and the petals at *p*, in fig. 22.

Cambium-layer, see p. 30.

Campanulate, bell-shaped, as in the Campanulas, p. 562 (fig. 24).

Campestris, growing in fields.

Candidus, pure white.

Canescens, greyish-white.

Capillary, like very slender threads.

Capitate, **Capitular**, **Capitulium**, growing in heads or close clusters, as with most flowers of the Composite order (fig. 25).

FIG. 24.—
CAMPANULATE.

FIG. 25.—CAPITULUM.

FIG. 26.—CAPSULE.

Capsule, a dry usually many-seeded seed-vessel, as in Poppy (fig. 26).

Carcerule, the name applied to the fruits of many of the Mallow and Hollyhock tribe (fig. 27).

Carneus, flesh-colour.

Carpel, the free or united divisions of the ovary or capsule.

Cartilaginous, tough and hard, often applied to the margins of leaves.

Caruncle, an outgrowth or excrescence at the scar (hilum) of some seeds, such as the Castor Oil plant (Ricinus) and the Viola (fig. 28).

Catkin, a spike of closely crowded flowers of one sex, in which the perianths are replaced

FIG. 27.—CARCERULE.

FIG. 28.—CARUNCLE.

by bracts, as in Alders, Birches, Hazels, Willows (fig. 7).

Caulicle, a little stem; the name sometimes given to the rudimentary stem in dicotyledonous seedlings.

Cauline, belonging to or produced from the stem.

Cell, see p. 22.

Centrifugal, applied to those forms of inflorescence whose terminal or central flowers open first.

Centripetal, flowering from the base or circumference towards the centre or tip, as in Wallflowers.

Cernuus, drooping, pendant.

Chaffy, covered with minute membranous scales.

Channeled, hollowed somewhat like a gutter on the upper surface of leaves or down the stem.

Chlorophyll, see p. 33.

Chryso, in compounds, signifies golden-yellow, as *Chrysanthus*.

Cilia, Ciliate, hairs placed like eyelashes on the edge of leaves, petals &c. (fig. 111).

Circinate, rolled up from the top towards the base like a crosier, as with the unfolding fronds of Ferns (fig. 29).

Circumscissile, divided by a circular slit or opening round the sides, as shown in fig. 90.

Cladodes, leaf-like branches, as in Butcher's Broom, p. 810.

Clavate, club-shaped, a body which is slender at the base and gradually thickening upwards.

Claw, the narrow and suddenly contracted base of a petal (fig. 30). *c* represents the claw proper, *b* the blade, and *s* the scales often seen in many flowers of the Pink order (p. 238).

Cleft, deeply cut, but not to the midrib.

Coccineus, scarlet or carmine tinged with yellow.

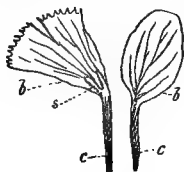

FIG. 30.—CLAW.

FIG. 31.—COCCI.

Coccus, Cocci, the separable carpels or nutlets of a dry fruit, as in Pelargoniums and Geraniums (fig. 31, shown as *s*).

Cohering, the attachment of similar parts, as the petals forming a gamo- or mono-

petalous corolla; and when the filaments of stamens are united.

Column, a term more particularly used to denote the united stamens and pistils in the Orchid family (p. 890). In fig. 32 *st* represents the stigmatic surface in a hollow on to which the pollinia (one of which is shown at *p*) must be placed to produce seeds. At *a* is shown the covering or lid over the pollinia.

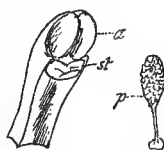

FIG. 32.—COLUMN.

Comose, furnished with hairs at the end, as some seeds like those of the Composite order.

Compound, formed of many similar parts, as the leaves of *Thalictrums*, *Aquilegias*, *Horse Chestnut*, *Acacia* &c.

Compressed, flattened laterally.

Conical, narrowing to a point from a broad circular base.

Connate, when two similar parts are slightly connected round the stem, as the leaves of some *Loniceras* (fig. 33).

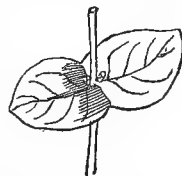

FIG. 33.—CONNATE.

Connective, the rib or part of the filament between the anther-cells, often produced, as in *Paris quadrifolia* (fig. 9, c).

Contorted, in æstivation, when one edge of a petal or sepal is covered and the other free or exposed; twisted.

Convolute, in æstivation or vernation, when one part is rolled up within another lengthwise.

Cordate, with two rounded lobes at the base, heart-shaped (fig. 34).

Coriaceous, leathery, tough.

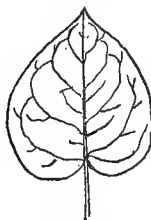

FIG. 34.—CORDATE.

FIG. 35.—CORM.

Corm, a fleshy bulb-like, solid, not scaly, underground stem, as in *Crocus*, *Gladiolus*, *Cyclamen*. See fig. 35, which represents the corm of a *Crocus*, the young one (*yc*) being above the old one (*oc*).

Corolla, the whorl of floral leaves, called

petals, between the calyx and stamens, usually coloured. Figs. 5, 22, 23, 36, 40, 49, 58 &c. show many kinds of corollas.

Corona, a term applied to the crown or trumpet in the centre of most Narcissus and Daffodil flowers (fig. 36, c).

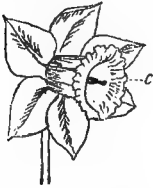

FIG. 36.—CORONA.

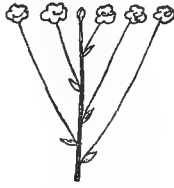

FIG. 37.—CORYMB.

Corymb, a raceme with the pedicels becoming gradually shorter as they approach the top of the flower stalk, so that all the flowers are nearly on a level (fig. 37).

Corymbose, in the form of a corymb.

Costate, ribbed.

Cotyledons, the seed lobes, often forming the first leaves of the plant (fig. 48, c).

Crassus, thick and fleshy.

Creomarp, the name given to the half-fruits or carpels of the Umbellifer family, which split apart when ripe (fig. 38).

FIG. 38.—CREOMARP.

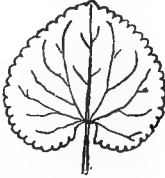

FIG. 39.—CRENATE.

Crenate, with rounded teeth on the margins of leaves. See fig. 39, which represents a heart-shaped (cordate) reniform (kidney-shaped) leaf with a crenate margin.

Crenulate, minutely crenate.

Crested, having an appendage like a crest, as in the cultivated forms of many Ferns and in Cockscombs (p. 762).

Crinitus, furnished with tufts of shaggy hair.

Cruciform, four parts, as petals, arranged so as to form a cross, as in Arabis, Wallflower, and most of the Crucifer order (fig. 40).

FIG. 40.—CRUCIFORM.

FIG. 41.—CUCULLATE.

Cryptogamous, see p. 121.

Cucullate, hooded, as the spathe of *Arum italicum* (fig. 41). See *Spathe*.

Cuneate, like a wedge, but attached by its point, usually applied to the shape of leaves or petals.

Cuspidate, abrupt, but with a little point at the end; something like apiculate but larger (fig. 42).

FIG. 42.—CUSPIDATE.

FIG. 43.—CYME.

Cyme, inflorescence formed of a terminal flower, beneath which are side branches each having a terminal flower and branches again similarly dividing, and so on, as in many plants of the Pink Order (fig. 43).

Cymose, arranged in a cyme.

Dealbatus, covered with a greyish-white powder.

Deca, in compounds signifies *ten*—as *decapetalus*, ten-petalled.

Deciduous, falling off, said of the leaves of large numbers of trees and shrubs in autumn; *Caducous* has the same meaning but is applied to the sepals and petals of most flowers after expansion.

Declinate, bent downwards, like the stamens in many flowers.

Declining, straight, but pointed downwards.

Decomound, subdivided more than three times, as the leaves of many Umbelliferous plants, *Thalictrum*s &c.

Decumbent, said of stems lying on the ground, but tending to rise at the tips.

Decurrent, when the limb of a leaf is prolonged down the stem, below the point of attachment of the midrib, as in the case of the common Comfrey, many Thistles &c. (fig. 44).

FIG. 44.—DECURRENT.

FIG. 45.—DECUSSATE.

Decussate, opposite leaves in four equal rows, as in many *Veronicas* (fig. 45).

Deflexed, curved downwards or towards the back.

Dehiscence, the mode in which an ovary or fruit opens to shed its seeds. Fig. 46 shows various ways in which the pods open; *a* is called *loculicidal*, and *b* *septifragal* dehiscence.

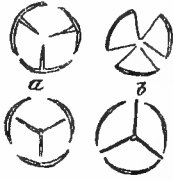

FIG. 46.—DEHISCENCE.

Deltoid, fleshy with a triangular transverse section.

Dentate, with short triangular teeth, as on the margins of many leaves.

Denticulate, finely toothed, like the *Camellia* leaf.

Depressed, when flattened at the top, like many Apples, Onions.

Di, in compounds, signifies *two*, as *diandrous*, 2 stamens.

Diadelphous, stamens in two bundles or fascicles, as in some Leguminous flowers (fig. 47).

Dichlamydeous, having both calyx and corolla, as in most of the flowers described between p. 131 and p. 759.

Dichotomous, when a branch, stem, or flower-stalk is much forked in pairs.

Diclinous, the same as *Unisexual*, when stamens and pistils are in different flowers.

Dicotyledonous, said of plants having two seed-leaves, and afterwards net-veined leaves &c., as explained at p. 122. Fig. 48 shows a seedling dicotyledon: *r* shows the true roots; *h* the hypocotyl or part between the true root and true stem; *c* the cotyledons or seed-leaves; *a*, the first pair of true net-veined leaves, and *p* the first true bud after the original one called a *plumule*.

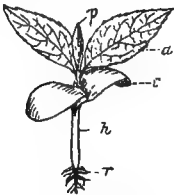

FIG. 48.—DICOTYLEDON.

FIG. 49.—DIDYNAMOUS.

Didynamous, having four stamens, two shorter than the others, as in many plants of the *Labiata* order (fig. 49).

Digitate, fingered leaves or lobes all start-

ing from the top of the petiole, as the leaves of the *Lupin*, *Horse Chestnut* &c. (fig. 50).

Dimidiate, the two halves of an organ very

FIG. 50.—DIGITATE.

FIG. 51.—DIMIDIATE.

unequal in size, like the leaves of *Begonias*, *Lime trees* &c. (fig. 51).

Dioecious, with the different sexes on different plants: stamens on one plant, pistils on another, as in *Willows*, *Aucubas*, *Hippophaë* &c.

Disc, a fleshy surface from which the stamens and pistils spring. The term 'discifloræ' has been applied to a large class of plants having these characters (p. 123). *Disc florets* are the central flowers in *Composite* plants like *Daisy*, *Marguerite* &c.

Dissected, deeply divided into many narrow lobes, like the leaves of *Umbelliferous* plants, *Thalictrums* &c.

Dissepiments, the partitions of an ovary or fruit, as shown in fig. 46.

Distichous, arranged in two opposite rows, as the leaves of *Taxodium distichum* (p. 983).

Divaricate, spreading at an obtuse angle.

Drupe, a fleshy fruit having a hard stone (putamen or endocarp, shown at *s*), as the *Cherry*, *Plum*, *Peach* &c. (fig. 52). *m* represents the fleshy edible portion called *mesocarp*, and *e* the skin or *epicarp*. See *Pome*, fig. 88.

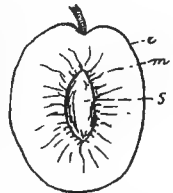

FIG. 52.—DRUPE.

Duramen, the heartwood or centre of *Dicotyledonous* trees, and the outer part of the stem of *Monocotyledonous*.

Echinate, clothed with spines or prickles, like the fruit of the *Sweet Chestnut*.

Elliptic, oval, but pointed at each end.

Elongate, much lengthened.

Emarginate, slightly notched at the end, as in the case of many leaves (fig. 53).

Embryo, the germ of a plant in the seed (see p. 24).

Ensiform, sword-shaped, as the leaves of Iris, Gladiolus &c.

Entire, said of leaves, petals, sepals not toothed nor lobed, nor divided at the edge.

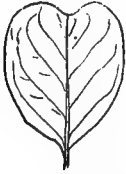

FIG. 53.—EMARGINATE.

FIG. 54.—EPICALYX.

Epicalyx, the term applied to the secondary calyx or sepals, as seen in Strawberries and Mallows. In fig. 54, *e* shows the epicalyx; *c*, the calyx (or sepals) proper; and *p* the petals.

Epidermis, the skin of a leaf or stem immediately underlying the cuticle.

Epigynous, when the parts of a flower are apparently seated on the ovary (fig. 55).

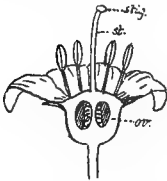

FIG. 55.—EPIGYNOUS.

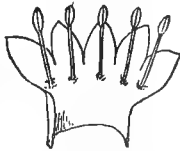

FIG. 56.—EPIPETALOUS.

Epipetalous, when the stamens are seated on the petals or corolla, as in Primroses &c. (fig. 56).

Equitant, overlapping each other, as the leaves of the Iris.

Erose, irregularly cut, as if gnawed, somewhat as represented in fig. 95.

Etærio, a fruit composed of several drupels, as in the Blackberry.

Exogenous, growing by additions to the circumference. This term was formerly used instead of Dicotyledonous.

Exserted, projecting beyond, as stamens protruding beyond the corolla or petals, as in figs. 55 and 56.

Exstipulate, without stipules.

Extrorse, applied to anthers which shed the pollen outwards, or away from the pistil.

Falcate, sickle-shaped, applied to leaves like some of the Eucalyptuses.

Fasciated, a term applied to stems which become abnormally flattened, and bear an extraordinary number of flowers or leaves, as is often seen in Asparagus and in *Lilium auratum*.

Fascicle, a cyme or crowded cluster of flowers placed on short pedicels of nearly equal length, as in Sweet William and other Pinks.

Fasciculate, when several similar parts are collected into a bundle and spring from the same spot.

Fastigate, applied to the branches of a tree when they are erect and close, like a tapering birch broom, as in the upright Cypress and Lombardy Poplar.

Fimbriate, fringed at the margin, like the petals of Carnations, Sweet Williams, and other Pinks, as shown in fig. 30.

Fistular, applied to the hollow stems and leaves of plants, as in many of the Umbelliferae.

Flaccid, weak, flabby, as when leaves droop for want of water.

Flavus, flavidus, pale yellow.

Flexuose, zigzag, usually changing its direction at each joint, like the branches of many trees, the Beech &c.

Floccose, with little tufts like wool.

Florets, the small flowers of Composite plants (fig. 25, *f*).

Fluitans, floating.

Fluviatilis, aquatic.

Follicle, an inflated 1-celled carpel, opening by a suture to which several seeds are attached, as in Trollius, Delphinium, Pæonia (fig. 57).

Free, separate, not joined together or with any other organ.

Fronde, the leaf-like part of Ferns, whether simple or divided.

Fruit, the seed-vessel or ovary with its ripe contents (seeds) and any external appendages.

Frutex, Frutescent, Fruticose, a shrub, shrubby; a woody plant destitute of a trunk, and branching from the base, or nearly so.

Fugacious, soon falling off, like the cap on the flower-bud of Eschscholtzia, the sepals and petals of Poppies &c.

Fulvus, dull yellow, buff.

Funnel-shaped, tubular below, but gradually enlarging upwards, like the flowers of some Convolvuluses (fig. 66).

Furcate, forked.

Fuscus, brownish.

Fusiform, spindle-shaped, thick tapering to each end, like the root of a long Radish.

Galbalus, the fleshy and ultimately woody cone of Junipers and Cypresses.

Galeate, shaped like a helmet, as the upper segment of the flower of Monkshood (fig. 58).

FIG. 57.—FOLLICLE.

Gamopetalous, when the petals are united together, as in Canterbury Bells, Laures-

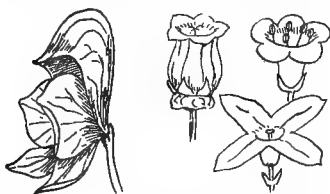

FIG. 58.—GALEATE.

FIG. 59.—GAMOPETALOUS.

tinus, Forsythias, and most of the plants described under Gamopetalæ in this work, p. 477, see figs. 59, 60, 63, 66, 67.

Gibbous, swollen on one side, like the flower of Valerian (fig. 60).

Glabrous, without hairs or down on the surface, as the leaves of Camellias, Aucubas, Cherry Laurels &c.

Gland, Glandular, a wart-like cellular secreting organ usually raised above the surface, as on the leaves of many Peaches.

Glandular-hairy, having hairs tipped with glands.

Glans, a name applied to the fruit of the Oak. In fig. 61, *c* represents the cupule, without the seed, and *g* the entire fruit.

Glaucous, sea-green with a whitish-blue lustre, like the thick fleshy leaves of *Echeveria secunda*, and many *Aquilegias* &c.

Globose, round like a globe, used in connection with inflorescences, like the heads of flowers of *Echinops Ritro*, as well as of single bodies like fruits, capsules &c.

Glumes, the scales enclosing the spikelet of flowers in Grasses.

Graveolens, possessing an intense odour, as in *Ruta graveolens*, the Rue.

Gymnos, in compounds signifies *naked*, as 'Gymnospermous,' naked-seeded, applied to the Coniferæ (p. 972).

Gynandrous, stamens and styles consolidated, as in the case of the Orchid family (p. 890), shown under Column (fig. 32).

Gynœcium, the female organs, that is, carpels or pistils collectively.

Habit, the port or aspect of a plant.

Hastate, a leaf enlarged at the base into two lobes pointing outwards nearly horizontally (fig. 62)

Head, a close terminal collection of flowers surrounded by an involucre, as in composite flowers; the same as a capitulum.

Herbaceous, the parts of plants which are not woody; also organs, or parts of them, of a green colour.

Hermaphrodite, flowers having both stamens and pistil, as in figs. 49, 55, 60 &c.

Hesperidium, a hard-rinded berry, like the Orange and Lemon.

Hirsute, with long soft hairs.

Hispid, covered with stiff hairs.

Hoary, with greyish-white down.

Hooded, flowers formed into a hood at the end, like the Aconites.

See Galeate (fig. 58).

Humilis, dwarf, low.

Hybrid, see p. 37.

Hypo, in compounds, signifies *under*, as hypogynous stamens, below the pistil, as shown in fig. 109.

Hypocotyl, the part of the young stem below the seed leaves, as shown at *h*, fig. 48.

Hypocrateriform, salver-shaped, said of flat corollas (fig. 63). At *t* is shown the 'tube' of such flowers.

Igneus, bright scarlet.

Imberbis, destitute of hairs.

Imbricate, arranged over each other like the scales of flower and leaf buds.

Impari-pinnate, pinnate, with an odd terminal leaflet, as shown in fig. 63, in which *l* indicates one of the 5 leaflets composing the whole leaf, *p* the stalk or petiole, and *st* the stipules. This is the same as *oddly-pinnate*.

Incised, deeply cut, as the leaves of the Hawthorns.

Included, not extending beyond the organs surrounding it; said of stamens which do not project beyond the mouth of the corolla.

Incomplete, some part wanting, as calyx, corolla &c. Plants belonging to the Incomplete section are described from p. 759 to p. 805.

Incurved, curved inwards.

Indefinite, many, but uncertain in number,

FIG. 62.—HASTATE.

FIG. 60.—GIBBOUS.

FIG. 61.—GLANS.

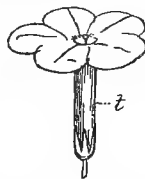

FIG. 63.—HYPOCRATERIFORM.

FIG. 64.—IMPARI-PINNATE.

said of stamens when more than 20 in number, as in Buttercups, Wild Roses &c.

Indehiscent, not bursting, said of fruits which do not open spontaneously when fully ripe.

Induplicate, when the edges of organs arranged in a valvate manner are folded inwards.

Indusium, the membranous covering of the spores-cases of many Ferns, as shown in fig. 65; *in* represents the indusium, and *sp* the spore-cases. A solitary spore-case burst and scattering spores is shown in fig. 105.

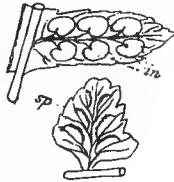

FIG. 65.—INDUSIUM.

Inferior, applied to an ovary when the calyx tube is adnate to it; and to the calyx when it is quite free from the ovary and below it, in which latter case the *ovary* is superior.

Inflexed, curved inwards.

Inflorescence, the arrangement of the flowers upon the stalk or peduncle. Inflorescences are spoken of as *racemose*, *cymose*, *spiculate*, *capitate*, *corymbose*, *paniculate* &c., according as to whether they are borne in the manner described by those terms.

FIG. 66.—INFUNDIBULIFORM.

Infundibuliform, funnel-shaped (fig. 66).

Internode, the space between two nodes or joints of a stem.

Interruptedly pinnate, when pairs of small pinnae alternate with large ones.

Introrse, said of anthers which open inwards towards the pistil or carpels.

Involucels, the involucre of secondary umbels.

Involucre, the whorled bracts at the base of an umbel, head, or single flower, as in figs. 25, and 113, *in*.

Involute, rolled from the back of anything, as towards the upper side of a leaf.

Irregular, petals or sepals unequal in size, or different in form in the same flower, as shown in figs. 5, 22, 23, 49.

Jugum, applied to a pair of leaflets; thus a leaf may be *unijugate*, *bijugate*, or *multijugate* according as there are one, two, or many pairs of leaflets (figs. 16, 17).

Keel, the name given to the lower pair of petals of Papilionaceous or Pea-like flowers. In fig. 5 the keel is shown at *k*.

Labellum, the same as 'lip,' q.v.

Labiata, lipped, as the flowers of many plants of the Labiatae family; a corolla or calyx divided into 2 unequal portions (fig. 67).

FIG. 67.—LABIATE.

Laciniate, divided into narrow irregular lobes.

Lacteus, white, with a faint tinge of blue.

Lacustris, growing in lakes.

Lamina, the blade of a leaf, as shown at *b* in fig. 98.

Lanceolate or lance-shaped, narrowly elliptic, and tapering to each end, as shown in fig. 68, in which *a* represents a lance-shaped leaf proper, and *b* an oblanceolate leaf, or a lance-shaped leaf reversed.

FIG. 68.—LANCÉOLATE.

Lance-shaped, shortly and bluntly lanceolate.

Lax, loosely arranged, often used in connection with the arrangement of flowers on the stems.

Leaflets, the subdivisions of compound leaves, as shown in figs. 16, 17, 50, 64.

Legume, a 1-celled and 2-valved seed vessel with the seeds arranged along the inner angle, as in the Pea, Bean &c. (fig. 69).

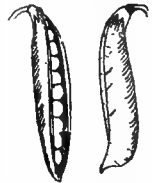

FIG. 69.—LEGUME.

Ligulate, strap-shaped, used in connection with the shape of leaves, and also of the 'ray' or outer spreading florets in plants of the Composite order (p. 492).

Ligule, a membrane at the base of the blade of the leaf of Grasses.

Limb, the flattened expanded part of a leaf or petal, as shown at figs. 70, 72, 73 &c.

Linear, very narrow and long.

Lingulate, tongue-shaped, long, fleshy, convex, blunt.

Lip, this term (and also the Latin equivalent *labellum*) is used particularly to designate the largest and most conspicuous segment of an Orchid flower, as shown in fig. 70. Here *l* is the lip, *col* the column, more highly shown at fig. 32, *p* the petals, *s* the sepals, and *us* the upper sepal.

FIG. 70.—LIP.

Littoralis, growing on the sea-shore.

Lobate, out into rather large divisions, as with many leaves.

Lobule, a small lobe.

Loculicidal (dehiscence), splitting down the back between the divisions, as shown in fig. 46, a.

Lucidus, shining.

Lunate, shaped somewhat like the new moon, but not so regular in outline.

Luteus, yellow.

Lyrate, a pinnatifid leaf with the lobes successively and gradually enlarging upwards from the petiole, and ending in one larger than the others (fig. 71).

FIG. 71.—
LYRATE.

Macros, in composition, long, large, as *macrophylla*, large-leaved.

Marcrescent, withering, but remaining in its place, like the calyx and corolla of many flowers.

Medulla, botanical name for pith. The **medullary rays** (see p. 30) are the 'silver grain' of the wood of Dicotyledons.

Membranous, of the texture of membrane; thin and flexible; more or less papery.

Micropyle, the orifice in the ovule (see p. 24).

Midrib, the large vein extending along the middle of a leaf from its petiole nearly or quite to the other end, as shown in the leaves in figs. 4, 34, 72 &c.

Mono, in compounds signifies *one*, as *monocotyledon*, one seed-leaf.

Monocarpic, flowering and fruiting only once, like some of the American Aloes (*Agave*) (see p. 21).

Monochlamydeous, the term given to flowers which have only one set of floral envelopes—either petals or sepals (see p. 126).

Monocotyledonous, having one sheathing cotyledon or seed-leaf, as in the Oat, Wheat, Barley, Onion, Lily, and most of the plants belonging to the Monocotyledonous group, described between p. 805 and p. 972.

Monœcious, with the stamens and pistils in separate flowers but on the same plant, as in Cucumbers, Marrows, Begonias, and Filberts. At fig. 7, *f* represents the female flowers, and *m* the male flowers of the Filbert on the same branch.

Monosepalous, monopetalous, when the sepals or petals are joined by their edges so as apparently to form one, the same as **gamosepalous** and **gamopetalous** (fig. 59).

Mucronate, abruptly tipped with a short point of the same texture.

Multi, in compounds signifies *many*, as *multiflorus* many-flowered, *multicolor*, many-coloured.

Multifid, divided into many parts.

Muricate, covered with sharp short points.

Mutabilis, changeable.

Mycelium, the 'spawn' of Fungi (see 'Mushrooms,' p. 1167).

Nectary, an organ which secretes honey. Nectaries are found at the base of the petals in Buttercups; in the Hellebores (p. 152) &c. the petals are reduced to nectaries, and in the *Parnassia* (p. 428) there is a radiating fringe of nectaries at the base of each petal.

Netted, covered with veins or nerves connected together like network, as shown in figs. 34, 39, 98, 101 &c.

Niger, black.

Nitidus, smooth and shining.

Nivalis, from snowy regions.

Niveus, snowy-white.

Node, a point in a stem where a leaf is produced.

Nucleus, the name given to the central and denser mass in the protoplasm (see p. 22).

Nudus, naked.

Nut, a hard dry 1-seeded seed-vessel.

Nutans, drooping, nodding.

Ob, in conjunction with terms means inverted; thus *obcordate* (fig. 72) means a heart-shaped leaf attached to the stalk by

FIG. 72.—OBCORDATE.

FIG. 73.—OBOVATE.

the narrow end; *obovate* (fig. 73) means ovate with the attachment at the narrow end, and the same with *ob-lanceolate* (fig. 68, b).

Oblong, long oval, equally broad at each end.

Obtuse, rounded or blunt.

Ocrea, a tubular membranous stipule surrounding the stem, as in many of the *Polygonums* (fig. 74).

FIG. 74.—OCREA.

Odes, Oides, a termination denoting similarity, resemblance.

Opposite, when two similar organs, as leaves, for example, grow one on each side of some body; or different organs are opposed to each other with a stem between them.

Orbicular, nearly round and flat, as in fig. 79, which shows an orbicular and peltate leaf of *Tropæolum majus*.

Oval, an ellipse; not broader at one end than at the other, and about twice as long as broad.

Ovary, the immature seed-vessel.

Ovate, egg-shaped; a short flat figure rather broader below the middle of its length (fig. 75).

Ovoid, the same as *ovate*, but applied usually to solid, and not flat, bodies, e.g. Apples, Pears, Plums.

Ovule, the name applied to the young seed before it has been fertilised by the contents of the pollen-tube.

FIG. 75.—OVATE.

Palate, the prominent part of the base of the lower lip which closes the mouth of a perianth corolla, as shown in the flower of Snapdragon at fig. 84, *p*.

Palea, the leaf-like parts of the flower of Grasses, inclosing the stamens, pistils, and hypogynous scales.

Palaceous, furnished with chaffy scales, as the receptacle of some Composites.

Palmate, spreading like the fingers of a hand from the same point.

Palmate-lobed, palmate with lobes, as in the leaves of the Maple.

Palmatifid, palmate, with the lobes extending to the middle of the leaf, as in the Castor Oil plant (fig. 76).

FIG. 76.—PALMATIFID.

Palmatisect, palmate, with the divisions extending to the bottom of the leaf.

Paludosus, **Palustris**, growing in marshy places.

Panicle, a raceme with branching pedicels (fig. 77).

FIG. 77.—PANICLE.

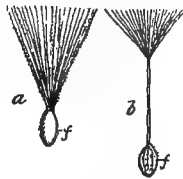

FIG. 78.—PAPPUS.

Pappus, the crest of the fruit in Composites, formed of the altered limb of the calyx. In fig. 78, *a* shows a sessile or stalkless pappus, and *b* a stalked or stipitate pappus; *f* is the fruit.

Parasitic, living on another plant, like the Mistletoe (p. 781).

Parenchyma, the soft cellular tissue of plants, the green pulpy material between the ribs and veins of leaves.

Parietal (placentation), on the sides or walls of the carpels, as shown in fig. 86, *p*.

Paripinnate, pinnate with an equal number of leaflets, as shown in fig. 85.

Patent, spreading widely, a term often used by botanists in connection with the petals of a corolla.

Pectinate, scalloped, crenately incised, like the teeth of a comb.

Pedate, palmate with three lobes and the lateral lobes having similar large lobes on their outer edge, as the leaves of *Helleborus*.

Pedate-lobed, pedate, with rounded divisions or lobes.

Pedatifid, pedate, with the divisions reaching to the middle of the leaf.

Pedatipartite, pedate, with the divisions nearly reaching to the bottom of the leaf.

Pedatisect, pedate, with the divisions extending nearly to the midrib.

Pedicle, the branch of a peduncle, otherwise the stalklet of an individual blossom, as shown in fig. 91, *ped*; here the peduncle or main flower stalk is shown at *p*, and the bracts are shown at *b*.

Peduncle, flower stalk.

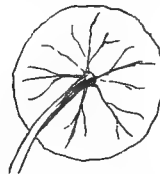

FIG. 79.—PELTATE.

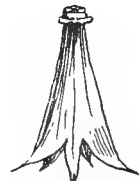

FIG. 80.—PELORIA.

Peloria, the term applied to the regular form of a usually irregular flower like the Common Toad-flax (fig. 80).

Peltate, when the point of attachment is on the face, not at the edge, of a leaf or other organ (fig. 79).

Penninerved, **Penniveined**, when the veins of a leaf radiate obliquely and regularly from the midrib (fig. 81).

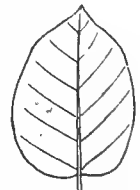

FIG. 81.—PENNI-NEINED.

Papilionaceous, like the flower of a Pea (fig. 5).

Pentagonal, with five angles having convex spaces between them.

Pentangular, with five angles and five flat or concave faces.

Perennial, of three or more years' duration, and flowering and fruiting each year.

Perfoliate, when the leaf completely surrounds the stem so that the latter seems to pass through it, as shown in fig. 82.

FIG. 82.—PERFOLIATE.

Perianth, the floral whorls when the calyx and corolla are not distinguishable, as in Tulips, Lilies, Orchids, Irises, Snowdrops &c., and many plants belonging to the Monocotyledons (p. 127).

Pericarp, seed-vessel, including adhering calyx if present.

Perigynous, growing upon the throat of the calyx around or above the ovary, as shown in fig. 83.

Perisperm, another name for the albumen of the seed (see p. 25).

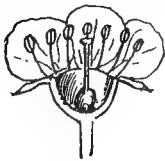

FIG. 83.—PERIGYNOUS.

FIG. 84.—PERSONATE.

Persistent, not soon falling off, as the leaves of evergreens.

Personate, a gamopetalous two-lipped corolla of which the lower lip is pressed upwards so as to close the opening, as in the Snapdragon (fig. 84). At *p* the 'palate' is represented.

Petals, the divisions of the corolla.

Petal-like, resembling petals in texture and colour as in Clematis, Hellebores, Marsh Marigold &c., in which the sepals have assumed the functions and appearance of petals.

Petiolate, having a petiole or leafstalk.

Petiole, the stalk of a leaf as shown at *p* in figs. 64 and 98; **Petiologule**, the stalk of a leaflet.

Phænogamous, **Phanerogamous**, having manifest flowers (p. 121).

Phylloclades, branches assuming the form and functions of leaves (see **Cladodes**).

Phyllum, in composition, a leaf.

Pileus, the 'cap' of a Mushroom and other Fungi.

Pilose, with scattered rather stiff hairs.

Pinnæ, the segments of a pinnate leaf (fig. 85).

Pinnate, when leaflets are arranged on opposite sides of a common stalk (fig. 83).

Pinnatifid, a leaf deeply cut into segments nearly to the midrib (fig. 18).

Pinnatipartite, pinnate, with the divisions acute, and almost free, as in the leaves of the Corn Poppy.

FIG. 85.—PINNATE.

Pinnatisect, pinnate, with the divisions reaching nearly to the midrib, as in the leaves of Water Cress.

Pinnules, the segments of pinnate leaves and fronds.

Pistil, the ovary, style, and stigma taken together. In fig. 55 *ov* represents the ovary, *st* the style, and *stig* the stigma. In fig. 109 the style—or portion between the ovary and stigma—is absent or very short.

Pith, the cellular tissue in the centre of Dicotyledonous stems.

Pitted, covered with small depressed spots.

Placenta, the process or body which bears the ovules in the ovary (fig. 86).

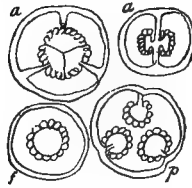

FIG. 86.—PLACENTAS.

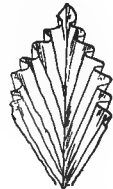

FIG. 87.—PLAITED.

Plaited, **Plicate**, folded in the manner of a closed fan, like many leaves before they are unfolded (fig. 87).

Plumose, feathery.

Plumule, the first or embryonic bud represented in fig. 48 at *p*.

Pod, a 1-celled and 2-valved seed-vessel with the seeds arranged along the inner angle. See **Legume** (fig. 69).

Pollen, the dust in the anther which serves to fertilise the ovules (fig. 9, *p*).

Pollination, the application of the pollen to the stigma, as described at p. 24.

Pollinium, the waxy pollen mass in Orchids (see fig. 82, *p*).

Polycarpic, fruiting more than once, several times (see p. 22).

Polygamous, a term applied to those plants having male, female, and hermaphrodite flowers intermixed on the same individual.

Polygonal, with many angles.

Polypetalous, with free, distinct, and separate petals, as in Buttercups, Roses, and most of the plants described from p. 131 to p. 477.

Polysepalous, with separate sepals.
Pome, the name given to such fruits as the Apple and Pear. In fig. 88 *st* represents the remains of the stamens in the 'eye' (*e*) of the fruit; *ct* shows the calyx tube; *en* the endocarp (core) within which are the seeds *s*; the fleshy edible part is represented at *m* (mesocarp), and *ep* the epicarp.

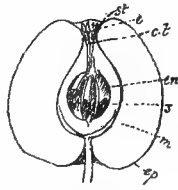

FIG. 88.—POME.

Pores, small, often roundish, holes.
Præcox, flowering early.
Pratensis, growing in meadows.
Prickles, hardened epidermal appendages resembling thorns, but not woody (see *aculeate*, fig. 3).

Procumbent, Prostrate, lying on the ground.
Prothallium or **Prothallus**, the flat deep green body resulting from the germination of a fern spore, and bearing male and female organs as explained at p. 1009. In fig. 89 the prothallium is shown at *p*, from the under surface of which are given off the rhizoids or root-like hairs, *rh*; and the first fern frond *f*, after fertilisation has taken place.

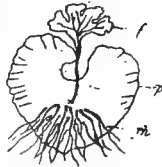

FIG. 89.—PROTHALLIUM.

Protoplasm, the living jelly-like contents of plant cells (see p. 22).
Pubescence, Pubescent, with closely adpressed down.
Pulverulent, covered with fine powdery matter.
Pumilus, short and dense in habit.
Punctate, having minute spots on the surface.

Putamen, the hard part or shell of stone fruit, like the Almond, Peach, Cherry, Plum (fig. 52, *s*).

Pyramidal, nearly in the shape of a pyramid, as shown at p. 1035.

Pyriform, Pear-shaped.

Pyxidium, a seed-pod or capsule opening horizontally by means of a lid, as in many plants of the Primula and Solanum orders. In fig. 90, *o* represents the operculum or lid; *s* the seeds; and *c* the calyx supporting the capsule.

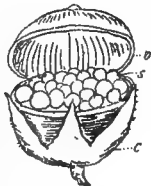

FIG. 90.—PYXIDIUM.

Quadrifoliate, with four leaflets diverging from the same point, as in *Paris quadrifolia* (p. 880).

Quinate, arranged in fives, as the leaflets of *Akebia quinata* (p. 179).

Raceme, a spike with stalked flowers, as that of the Laburnum, Currant, Wallflower &c. (fig. 91); *b* represents a bract; *ped* the stalklet or pedicel of the individual flower; and *p* the peduncle or main stalk of all the flowers in the raceme.

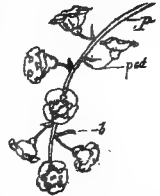

FIG. 91.—RACEME.

Racemose, flowering in a raceme.
Rachis, the central stem of some kinds of inflorescence. The stalk of the frond of Ferns above the lowest pinnæ.
Radical, springing from just above the root, said of the leaves of many low-growing tufted plants.

Radicle, the first root of a young plant emerging from the seed (fig. 48, *r*).

Ramosus, much branched.

Ray, parts diverging in a circle from a central point. **Ray-florets** are the outer strap-shaped ones, as in the Daisy and many other Composite plants.

Receptacle, the dilated top of the stalk bearing the flowers in Composites (see *Torus*).

Recurved, bent moderately backwards.
Reflexed, bent considerably backwards.

Regular, all the parts of each series of a flower alike, as in figs. 40, 59, 63, &c.

Reniform, transversely oval, but broadly cordate at the base; kidney-shaped (fig. 92).

Repens, creeping.
Reticulate, forming a network.

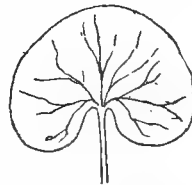

FIG. 92.—RENIFORM.

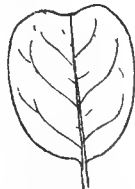

FIG. 93.—RETUSE.

Retuse, abruptly blunt with a notch in the middle (fig. 93).

Revolute, rolled back, as towards the under side of a leaf.

Rhizome, a thickish prostrate more or less subterranean stem producing roots and leafy shoots, as in Irises, Solomon's Seal &c.

Ringent, a 2-lipped widely open or gaping corolla, like that of the Dead Nettle (fig. 65).
Riparius, growing on the banks of streams or lakes.

Rootstock, a thick short rhizome or tuber. The term is loosely applied by gardeners to mean the clump, set, or mass of roots of an herbaceous perennial plant.

Rosette, a collection of leaves growing close together, and radiating from the main stem.

Rosulate, disposed in the form of a rosette.

Rotate, a monopetalous corolla with a short tube and very spreading limb (fig. 94), as in Potato and other flowers of the Solanum order.

Ruber, red of any tint.

Ruderalis, growing amongst rubbish.

FIG. 94.—ROTATE.

FIG. 95.—RUNCINATE.

Rugose, covered with a net of lines enclosing convex spaces, like the leaves of *Rosa rugosa*.

Rugulose, finely rugose.

Runcinate, where the lobes of leaves are directed towards the base (fig. 95).

Runner, a prostrate shoot rooting at its end, as in the Strawberry.

Rupestris, growing on rocks.

Sabulosus, growing in sandy places.

Sagittate, like the barbed head of an arrow, the auricles or lobes pointing backwards (fig. 96) not outwards as in *Hastate* (fig. 62).

Salver-shaped, a corolla with a long slender tube and flat limb, the same as **hypocra-teriform** (fig. 63).

FIG. 96.—SAGITTATE.

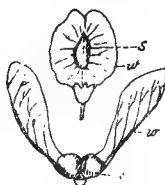

FIG. 97.—SAMARAS.

Samara, applied to such winged indehiscent fruits as the Ash, Elm &c. (fig. 97).

Saxatilis, growing on rocks or stones.

Scaber, scabrid, scabrous, rough to the touch.

Scales, minute rudimentary leaves or appendages to petals, as in many Pinks &c.

Scandens, climbing.

Scape, a leafless flower stem springing from the root, like that of Tulips, Hyacinths, Daffodils.

Scarious, with a thin, dry, shrivelled appearance.

Scorpioid, rolled up in a somewhat crosier-like fashion. See **Circinate**.

Secund, all turned towards one side.

Sempervirens, evergreen.

Sepals, the division of the calyx.

Septicidal (dehiscence), separating through the dissepiments (fig. 46, b).

Septum, the partition of an ovary or fruit.

Sericose, silky.

Serotinus, late.

Serrate, toothed like a saw, like the margins of many leaves (fig. 98).

Serratures, teeth like those of a saw.

Serrulate, with very small saw-like teeth.

Sessile, without a stalk, like many leaves.

Seta, a bristle; a bristle tipped with a gland; a slender straight prickle.

Setaceous, like a bristle.

Setose, bearing bristles or setae usually ending in glands.

Sheath, the lower part of a leaf or its petiole, which forms a vertical sheath surrounding the stem.

Silicle, a silique about as long as it is broad (fig. 99).

FIG. 98.—SERRATE.

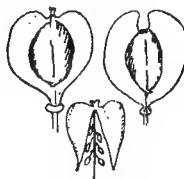

FIG. 99.—SILICLES.

FIG. 100.—SILIQUES.

Silique, a long pod-like fruit of *Crucifers* having its edges connected by an internal membrane (fig. 100).

Simple, not compound; not branched, lobed, or divided.

Sinuate, having many large blunt lobes, as in Oak leaves (fig. 101).

Sinus, the recesses of a lobed organ, as shown in the leaf at fig. 101.

FIG. 101.—SINUATE.

Smooth, free from all kinds of roughness.
Solitary, growing singly, said of flowers when only one is borne on the stalk.

Spadix, a succulent spike bearing many sessile closely placed flowers, as in fig. 99, where *b.st* represents the barren stamens; *f.st* the fertile stamens; *bp* the barren pistils; and *fp* the fertile ones capable of producing seeds.

Spathe, a large bract often inclosing a spadix, as shown in fig. 41; *s* is the spathe and *sp* the spadix.

FIG. 102.—SPADIX.

FIG. 103.—
SPATHULATE.

FIG. 104.—SPIKE.

Spathulate or **Spatulate**, oblong, with a long and narrow base; spoon-shaped (fig. 103).

Spike, a long simple axis with many sessile flowers like a raceme except that the individual flowers have no stalks; see fig. 104, representing the flower spike of Plantain.

Spikelet, the small group of flowers in Grasses enclosed within one or more glumes.

Spine, a stiff, sharp, woody, persistent thorn, as seen in Gooseberries, Barberries, Black-thorns &c.

Spinose, furnished with spines.

Spinulose, with small, often very minute spines or prickles.

Sporangium, a single spore case which contains the spores or seeds of Ferns. In fig. 105 *sp* represents the dust-like spores falling from the ruptured case; and *u* represents the stiffer ringed midrib or annulus (see **Indusium**).

FIG. 105.—
SPORANGIUM.

Spur, a tubular extension of the lower part of a petal or monopetalous corolla, as seen in Columbines and *Tropæolum* (fig. 22).

Squamatus, clothed with scales.

Squarrose, rough with projecting or deflexed scales.

Stamen, the male organ of a flower, usually formed of a filament and anther. In fig. 9, *f* represents the filament; *a* the anther shedding the pollen *p*; and *c* the connective or midrib between the 2 anther

lobes. The connective is produced in one case, as in the stamens of *Paris quadrifolia*.

Staminode, rudimentary organs next to the stamens; usually barren or antherless stamens.

Standard, the upper or posterior petal of a Pea-flower which is outside the others in the bud, shown at *st* in fig. 5.

Stellate, radiating from a centre like a star; applied to flowers of which the petals are narrow and distant and radiate like the rays of a star.

Stellulate, like minute stars.

Stigma, the cellular part at the top of a carpel or style to which the pollen adheres, shown at *st* in fig. 1, and *stig* in figs. 56, 109.

Stipe, the stalk of Fern fronds up to the lowest pinna.

Stipitate, stalked; applied to carpels which are more or less slightly elevated on a stalk. A stipitate pappus is shown in fig. 78, *b*.

Stipules, leaf-like appendages at the base of the petiole, shown at *st* in figs. 64, 98, 111 (*s*).

Stolon, an offset or runner producing roots at intervals, as in Strawberry.

Strap-shaped, not very narrow nor long, and with nearly parallel sides; the same as ligulate.

Striate, with slender streaks or furrows.

Strobilus, a flower-head or cone consisting of several overlapping scales, as seen in many members of the Conifer order (p. 972).

Style, the slender termination of a carpel bearing the stigma, shown in fig. 83.

Sub, in composition means almost or nearly, somewhat; thus *sub-rotund* means nearly round; *sub-shrubby*, somewhat shrubby; *sub-orbicular*, roundish &c.

Subulate, awl-shaped, tapering from the base to a fine point, a long narrow triangle.

Sucker, a leafy stem produced at the end of an underground shoot, as with Plum trees, Lilacs &c.

Suffruticose, rather shrubby.

Sulcate, furrowed, like the stems of many Umbelliferous plants.

Superior, above anything; a calyx is superior when its tube is wholly attached to the ovary; half superior when attached only to the lower half of it; an ovary is superior when wholly free from and above the calyx.

FIG. 106.—
STROBILUS.

Supra-decompound, subdivided many times.

Sylvaticus, Sylvestris, inhabiting woods.

Syn, signifies union or growing together, as *syncarpous*, when the carpels are consolidated, as shown in fig. 27, or *syngenesious*, when the anthers are united, as in most flowers of the Composite order.

Tap roots, roots with stout tapering bodies developed direct from the seed, like Carrots and Turnips (fig. 107).

Tendril, a twisting slender organ for laying hold of objects.

Tennis, slender, thin.

Terete, applied to round or nearly round stems, like an ordinary lead pencil or goose quill.

Ternate, growing in threes, as shown in the portions of fig. 19, and in fig. 108, like the leaves of *Choisya ternata* (p. 296).

Testa, the outer skin of a seed.

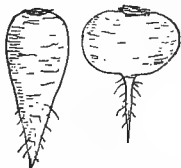

FIG. 107.—TAP-ROOTS.

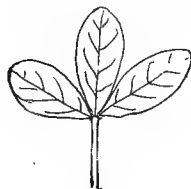

FIG. 108.—TERNATE.

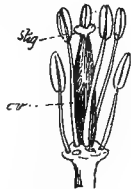

FIG. 109.—TETRA-DYNAMOUS.

Tetradynamous, having six stamens, of which two are shorter than the other four, as in the Wallflower (fig. 109) and most plants of the Crucifer order.

Tetragonous, with four angles and four convex faces, like the stems of Dead Nettles and many other plants of the Labiate order.

Thalamus, the receptacle or torus of a flower.

Thorn, an abortive branch with a sharp point; distinguished from a Prickle by being woody.

Throat, the orifice of the tube of a gamopetalous corolla or gamosepalous calyx.

Thyrsoïd, having a close-branched raceme of which the middle is broader than the ends.

Tomentose, covered with cottony entangled hairs, forming a matted shagginess called *tomentum*; felted.

Toothed, having small tooth-like divisions on the margin.

Torus, the part on which the divisions of a flower or fruit are seated; the same as receptacle.

Tri, in compounds, signifies *three*.

Triangular, with three angles and three flat faces.

Trichotomous, in forks of three prongs successively repeated.

Trifid, when leaves are divided about half way down into three parts, as shown in fig. 110.

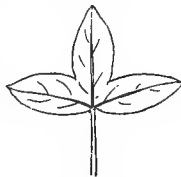

FIG. 110.—TRIFID.

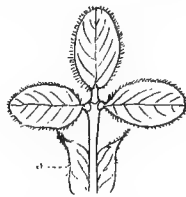

FIG. 111.—TRIFOLIATE.

Trifoliate, composed of three leaflets, as the leaves of Clover shown in fig. 111, where the leaflets are ciliated on the margins; the stipules at the base are shown at s.

Trifoliate, having three leaflets proceeding from the same point, as in fig. 19.

Trigonus, with three angles and three convex faces.

Tripartite, divided into three parts nearly to its base; more than trifid.

Tripartite, three times pinnately subdivided, as if the leaflets in fig. 17 were again divided.

Triquetrous, having three angles and three concave faces.

Tristis, dull-coloured.

Truncate, blunt as if cut off at the end, like the leaf of the Tulip tree (fig. 112).

Tube, the pipe formed by the cohesion of the petals in a gamopetalous corolla, as shown in fig. 63, t.

Tuber, a thickened and underground fleshy part of the stem, as the Potato and Jerusalem Artichoke.

Tubercles, little round knobs.

Tubercular, tubercled, tuberculate, covered with little knobs.

Tuberous, like a tuber, but not part of the stem.

Tubular, hollow and nearly cylindrical, something like *fistular*.

Turbinate, top-shaped, conical and attached by its long point, like many Pears.

FIG. 112.—TRUNCATE.

Uliginosus, inhabiting swampy places.

Umbel, when many stalked flowers spring from one point and reach about the

same level, as in fig. 113. *Partial umbels* are umbels seated upon the branches of an umbel, the whole forming a *compound umbel*.

Umbrosus, growing in shady places.

Unarmed, where stems and leaves are destitute of spines or prickles.

Undulate, having a wavy margin.

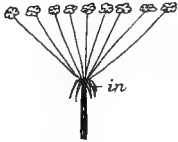

FIG. 113.—UMBEL.

FIG. 114.—URCEOLATE.

Unilateral, turned to one side.

Urceolate, like a pitcher contracted at the mouth, like the flowers of many Heaths, as shown in fig. 114.

Urens, stinging, as the hairs of the common Stinging Nettle.

Valvate (æstivation), sepals or petals meeting at the margins, but not overlapping each other, as shown in fig. 115.

Veins, the nerves in leaves and their ramifications, as shown in figs. 34 &c.

Velutinous, velvety, as the surface of leaves.

Ventral, the anterior part of an organ.

Ventricose, swelling unequally on one side,

FIG. 115.—VALVATE.

somewhat like the corolla of Valerian shown in fig. 60.

Vernalis, produced in spring.

Vernation, the arrangement of the leaves when in bud.

Verrucose, warty.

Versatile, affixed in the middle, applied to anthers like those of Lilies which swing backwards and forwards with the movement of the air. In fig. 9 a versatile anther is shown in the middle.

Verticillate, arranged in whorls.

Villous, shaggy with loose long soft hair.

Virens, green.

Virgatus, twiggly.

Viridis, clear full green.

Viscosus, clammy.

Volubilis, twisting.

Wedge-shaped, like a wedge, but attached by its point.

Whorl, whorled, similar organs arranged in a circle round an axis, as the leaves of *Galium*, *Asperula* (fig. 116), and of some Lilies.

Winged, having leaf-like or membranous expansions, like the stems of many Thistles.

Wings, the lateral petals of a Pea-flower, as shown at *w* in fig. 5; the flat membranous appendages of some seeds.

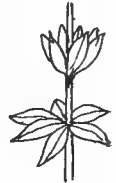

FIG. 116.—WHORL.

Zygomorphic, said of a flower which can only be bisected in one plane so as to show two similar halves. Most Orchid flowers bisected vertically are zygomorphic, as are also many flowers of the Labiate family (p. 742), the Aconite (p. 162) &c.

INTRODUCTION

THE cultivation of plants at the present day has been brought almost to the highest point of perfection. Far greater attention is now given to the problem as to how the finest Flowers, Fruits, and Vegetables can be produced in the best way at the least cost than at any previous period in our history. The whole country is alive to the importance and necessity of making the land produce as much as possible in the best possible way. County Councils are lavishing money to have gardening taught either in schoolrooms or in gardens, but as yet have not decided upon any definite plan whereby those taught are likely to obtain any or much benefit from what they learn. And yet, it is a curious fact that, although we know a good deal more about plants now than our ancestors did, and though thousands of plants, natives of all parts of the world, are grown in our gardens that were quite unknown to them, still there has been practically but little change in the principal methods of cultivation. The importance of tilling and manuring the soil and bringing it into a state of fertility has been recognised from the earliest ages, while little or nothing was known of its nature and composition, or the chemical changes that take place in it, or that are produced by rain, heat and cold, &c. The proper times for Digging, Planting, Sowing seeds, and various other operations were also well known, and modern gardeners still continue to work on the same old lines. The ancients were also acquainted with the arts of Budding, Grafting, Layering, Pruning, Thinning Out, Transplanting &c., and all these operations were alluded to as commonplaces by the poet Virgil before the Christian Era in his well-known *Bucolics*. It thus appears that, notwithstanding the march of time, the principles of cultivation remain the same in all ages, and gardeners have only to

apply them with a fair amount of common sense, and attention to details necessitated by the nature of any particular plant.

Although, unhappily, a good knowledge of plants, their structure and requirements, does not necessarily mean that a person with this knowledge is also a good cultivator, it is nevertheless true that a gardener who turns such knowledge to practical use has a much better chance of producing fine flowers, fruits, and vegetables than he who is not so well equipped in this respect. Many gardeners—amateur and professional—are like poets: they are born and not made; they seem to know instinctively and exactly how to cultivate any particular plant; or if they do not, it is not very long before they find out. Without knowing it, such gardeners carry out the true principles of cultivation, which after all are in strict accordance with natural laws, and therefore the more one studies the nature of a plant and its requirements the sooner will he be able to grow it to perfection in his garden.

Before one can hope to grow a plant of any kind satisfactorily it is obvious that at least some knowledge is required in regard to the functions of the various parts of plants, the soil and its composition, and treatment, and many other details. An attempt has been made in this direction with a view to giving the reader information that may be of use to him in the garden. It is most important to have a clear idea as to the functions of the Roots, Stems, Leaves, Flowers, Fruits, and Seeds, as this will prevent many mistakes in cultural treatment. A doctor who did not understand the anatomy of his patient, and what he required to keep him in good health, would be a sorry practitioner. So with the person who would grow plants successfully. He must understand them, he must know something about their relationship to each other, the countries in which they grow wild, the kind of soil that suits them best, whether they prefer sunshine or shadow, moist or dry situations, and how best they may be increased so that they shall not die out of cultivation altogether, either through old age, ill-treatment, or other causes.

PART I

THE LIFE HISTORY OF CULTIVATED PLANTS

FROM a gardening point of view cultivated plants may be said to be constructed on a common plan, although there is a vast variation in details. Speaking generally, most plants are characterised by having Seeds, Roots, Stems, Leaves, Flowers, and Fruit, and may be annual or biennial herbs, or herbaceous or woody perennial plants.

Whatever group they belong to, their corresponding parts are constructed on the same principle and perform the same functions.

As the good cultivation of plants depends to a very large extent upon a more or less intimate knowledge of their nature, it may be useful if a brief account is given of the various organs mentioned above.

GROWTH OF PLANTS

Perhaps one of the first things people notice about plants is that they *grow*. Plants, somewhat like human beings and animals, are living objects, and are affected in much the same way by heat, cold, moisture &c. They also are to be found in all parts of the world, and according to the climate in which they grow are looked upon as being more or less hardy or tender. They pass from what may be called the infant or seedling stage to maturity, and then more or less slowly or quickly begin to decay and ultimately die. They have a complete cycle of existence, and this cycle is completed by some in a much shorter time than others. Annuals and biennials for example complete their cycle of existence in one or two years, but others like herbaceous perennials, trees and shrubs &c., exist for several years before the individual becomes exhausted. And yet while an individual plant may pass from the seedling stage to death in one or more years, according to its nature, as a rule it makes provision for reproducing itself again before actually dying. This process of reproduction is naturally carried on by means of seeds. Some plants like annuals and biennials bear only one crop of seeds and then die. Plants with these characteristics—that fruit only once—are said to be *monocarpic*.

Other plants, however, which may live for very many years, like some of the American Aloes, also fruit or produce seeds only once in a lifetime and then die. These are also said to be *monocarpic*. Nearly all our hardy herbaceous perennials, and woody perennials like trees and shrubs—Apples, Pears, Plums, Oaks, Ashes, Beeches &c.—fruit or produce seeds year after year for several generations, and are therefore said to be *polycarpic*.

It little matters, however, whether plants be annuals, biennials, or perennials, whether they produce only one crop of seed or many, they are all governed by the same laws of *Growth*.

Plant-cells.—To give the reader a better idea of how this process called growth takes place, it is necessary to point out that plants are made up of cells and tissues. Some plants, indeed, like the green Protococcus seen on damp walls, the mould on old leather &c., are very simple in their structure and often consist of one cell only. And it is in the contents of the individual cells, the presence of which was discovered in 1667 by Robert Hooke, that we must look for the origin of growth.

Protoplasm.—Every plant cell in a young stage is filled with a slimy jelly-like substance to which the name of *Protoplasm* was given in 1846 by a German botanist, Hugo von Mohl. This protoplasm is practically the seat of life. It is constantly undergoing more or less rapid changes in composition, absorbing new food, digesting it, and expelling all waste or worn-out materials. When the cells are young they are completely filled with it, but as they grow old the protoplasm begins to break up into strands, leaving spaces in between which become filled with watery sap absorbed and drafted up by the roots. By-and-bye the protoplasm recedes from the centre of the cell to line the cell walls, and ultimately vanishes altogether with age, the refuse from it going to make the cell walls thicker and harder, and producing what we know as wood or fibre.

Before this stage is reached, however, the protoplasm, or rather the central portion of it called the *nucleus*, divides and forms a new cell. This, like its parent, becomes surrounded with a cell wall, and then becomes practically an independent individual working out its own life history in the same way. When it is remembered that plants are made up of millions of these cells containing protoplasm, and that with the advance of age each mass of protoplasm is capable of propagating itself by division, it is not so very difficult to account for what we understand as growth—how plants often attain enormous heights, and the trunks of trees great diameters—according to their nature.

Although each mass of protoplasm is as it were completely enclosed within its own cell walls, it is not, however, cut off from all communi-

cation with the protoplasm in the neighbouring cells. It is supposed that thin microscopic strands of protoplasm pass through the cell walls from one protoplasmic mass to another, and also that the fluid from a well-filled or turgid cell is diffused through the cell walls into a comparatively empty one by a process which has been termed *osmosis* or *endosmosis*, and that in this way the cell-sap is drafted to the outermost points of the shoots of plants no matter how tall. As the protoplasm in each cell is therefore dependent for its support on the food dissolved in the cell-sap it naturally follows that no solid substance can possibly enter as such into the system of a plant. The protoplasm is formed, or forms itself, out of the food which has been absorbed in a liquid state, and it then proceeds to build up the various tissues of the plant which we know as shoots, stems, leaves, flowers &c. When the liquid or watery sap in the cells becomes excessive it is exhaled or breathed out into the atmosphere in the form of vapour by means of the pores of the leaves referred to below under 'Transpiration' at p. 34, and fresh supplies as wanted are absorbed by the roots, but only under favourable climatic conditions. To sum up, the whole plant is dependent on the work of the protoplasm, and so long as this continues to perform its functions, so long will the plant live and produce in due course its flowers and fruits. Anything therefore that tends to interfere with the work of the protoplasm, such as too much heat or cold, too much drought or moisture, too much light or shade, also stops the *growth* of the plant, and until proper conditions are restored the plant is likely to die because the protoplasm cannot perform its work in a satisfactory manner.

The great aim of the gardener, therefore, is to choose the most favourable conditions for his plants so that there will be no interference or check to the mysterious work carried on within the cell walls by the protoplasm. If a plant comes from a tropical climate, he endeavours to imitate the natural warmth by growing it in a hothouse, as he very soon discovers by the drooping and withering leaves and stems that a cool temperature will be injurious. In the same way plants from cold regions will be injured by excessive heat. As this work, however, only deals with plants which will grow in the open air in our own climate, the reader need not concern himself much about artificial heat, although he will find many cases in which he is advised to use hotbeds for raising seeds &c., and to place his plants in the warmest and sunniest, in the coolest and shadiest, in the driest or dampest positions in his garden; but these instructions are all based upon this one principle of placing a plant under the circumstances most favourable to the work to be performed by the protoplasm in the cells.

THE SEED

It has been stated above that the growth of a plant takes the form of a cycle, and it is therefore difficult to take any one organ and say 'growth begins here.' This cannot be said of the root, as it is the outcome of the seed; it cannot be said of the leaves, as they are outgrowths of the stem; and it cannot even be said of the seed, which is produced by the ripened fruit. As, however, for practical purposes it is necessary to start somewhere, the most logical beginning from a gardening point of view seems to be the Seed, which we will therefore consider.

Many years ago, the late Dr. Lindley described a seed as being 'a living body, separating from its parent and capable of growing into a new individual of the same species. It is a reproductive fragment, or vital point, containing within itself all the elements of life, which, however, can only be called into action by special circumstances.'

As popularly understood, seeds are only produced by Flowering Plants or 'Phanerogams' (p. 121). They are the result of the ovules (either naked, as in the Pine order; or enclosed in carpels, as in most other Flowering Plants) being fertilised by the pollen tube. Each fertilised seed contains an embryo, or the rudiments of a young plant. When placed in a suitable temperature, with moisture, they are capable of reproducing all the characters of their parents. The so-called 'seeds' or spores of Ferns differ very much from those of Flowering Plants, and the way in which they are reproduced is explained at p. 1009.

The process of forming seeds takes place somewhat in this way. When the grain of dust or pollen from an anther in the flower falls on to the stigmatic surface of the carpel, the grain of pollen begins to grow much in the same way as a seed in the soil, with the exception that all the growth is downwards. A microscopic thread called the pollen tube makes its way from the pollen grain downwards through the tissue of the carpel, and eventually reaches the ovule contained within the walls of the ovary. At one end of the ovule there is a small hole called the *micropyle*. The pollen tube enters this and comes in contact with a cell much larger than the others called the *embryo-sac*. Within the embryo-sac and close to the micropyle are three other cells, one of which called the *egg-cell* or *embryonic vesicle* receives the contents of the pollen tube and is thus fertilised. This operation, sooner or later, results in the production of what is commonly known as a seed. After fertilisation, the nuclei in the masses of protoplasm in the cells divide as explained above and form new masses, and thus fill up the interior of the embryo-sac. Eventually the embryo, or young plant,

fills up the entire space within the seed coats as in the case of the Pea, Bean, Horse-Chestnut, Oak &c. ; or it may occupy only a very small space as in Wheat, Onion &c., and remain imbedded in a substance at one time called *albumen*, but now more generally called *perisperm*.

When the embryo occupies the whole seed, as in the case of the Bean &c., all the reserve material for the purpose of nourishing the young plant is stored up in the fleshy seed-leaves or *cotyledons*, and it is from these that food supplies are drawn until the young root has developed sufficiently to absorb food from the soil, after germination has taken place. In the case of other seeds, however, like those of the Wheat and Onion, the young plant is fed upon the albumen or perisperm, and not on the seed leaves, until roots are formed.

Germination.—Seeds germinate as the result of a certain amount of heat, moisture, and air. The seeds of some plants germinate in a much lower temperature than others, but there is a certain point called the ‘optimum’ at which seeds of any given plant will sprout more readily than at a point below or above it. The best or ‘optimum’ temperature for germination varies according to the nature of the plant or species, and the gardener learns by experience which temperature is most suitable for raising the seeds of any particular plant. He knows for instance that the seeds of many plants will sprout sooner if they are sown upon a hotbed than if they are sown in the open ground where the temperature may be 10° or 20° lower. He also knows that a certain amount of moisture is absolutely necessary, and that the free circulation of air between the particles of soil shall not be impeded, as he usually takes particular care to have the soil well drained, so that the water and consequently the air shall pass through it freely. Speaking generally, the seeds of most of the plants described in this work germinate readily either out of doors in autumn or spring ; in cold frames without artificial heat ; or in the gentle heat of a hotbed or greenhouse, say 60° to 70° F. or even less.

Heat and Cold.—When a seed ‘sprouts’ or germinates as a result of the suitable conditions referred to above it is obvious that *growth* is taking place. It undergoes a change from the apparently dried condition in which it was before its contact with moisture or suitable heat. In fact, heat is the prime mover of life in the seed ; hence by the use of hotbeds or frames or greenhouses several degrees more heat are obtained than out of doors. Chemical changes take place in the seed ; water is absorbed from the soil through the seed coats ; the latter are soon unable to contain their swollen contents and consequently burst. The first seed-leaves are pushed upwards through the soil, and the tiny rootlet downwards into it. These signs are simply an indication of the work that is

being done by the protoplasm in the cells as already explained. From the water absorbed through the seed-coats, the protoplasm receives a supply of food and proceeds to manufacture it, with the result that the nuclei in the masses of protoplasm divide and produce other nuclei, and these again in due course carry out the same process, not only until a plant is fully developed but until it dies.

Vitality of Seeds.—Some seeds retain their vitality for several years—that is, their power of germinating does not appear to be much injured by being kept a long time—while others very soon lose it. For practical purposes it is preferable to obtain fresh and thoroughly ripened seed to secure the best results. The stories as to the germinating power of mummy-wheat 2,000 years old are fables, but many seeds will retain their vitality and produce good plants after careful storing for 5 to 10 years.

THE ROOT

To the ordinary observer every part of a plant which happens to grow naturally underground is regarded as a 'root.' This looseness of expression is not altogether confined to the uninitiated, as the term 'roots' is also applied by florists and nurserymen to entire plants, such as Pansies, Violas, Sweet Williams, Foxgloves, Double Daisies, and many other plants in which a large trade is done during the spring months. At present, however, we are chiefly concerned with real roots, and it is necessary that the gardener should have a clear idea as to their origin and function.

The first Root is the downward growth from the lower end of the 'caulicle' or basal portion of the embryo. It usually breaks through the seed coat at germinating time, before the cotyledons emerge to the light, the object in view by nature evidently being that the young plant should be provided with roots as early as possible after growth has commenced in the seed. When the first root persists and continues to grow it becomes what is known as a tap-root, and is present in all Dicotyledonous plants (p. 131 to p. 805) raised from seed. Good examples are seen in the Carrot, Parsnip, and Beetroot as represented at fig. 107 in the Glossary. As the tap-root in many plants has a tendency to grow down into uncongenial and sterile parts of the soil, it may be prevented from developing in a downward direction by more or less frequent transplanting; this injures the tip, stops its growth, and causes the more desirable fibrous roots to develop from the sides. Roots branch in all directions and apparently without system, and become finer and more threadlike towards the tips. They usually

avoid the light, bear no leaves or buds, and are generally of a pale or whitish colour although sometimes with coloured juice.

Functions.—The main function of the root is to obtain liquid food from the soil. The tips of the root are chiefly concerned in this work, the older portions merely serving as holdfasts for the plant, and as channels for conveying the food to the stems and leaves. The extremity of each root-fibre is covered with a cap, formerly called a 'spongiole,' which protects a mass of young and active cells forming the 'growing point.' As the roots push their way in a somewhat corkscrew-like fashion through the soil, the outer layers of the root-cap wear out and are replaced from within by the discarded layers of the growing point. The contents of the cells of the growing point are very sensitive to heat, cold, and moisture, and under favourable conditions absorb water and whatever plant food is dissolved in it in large quantities. During the spring and summer they are most active, gradually subsiding towards autumn and becoming almost inactive in winter. When plants are moved during the active state of growth most of the root-tips are injured or broken, and the supply of food and water is cut off from the plant until new roots are formed. Sometimes plants moved at this period never recover from the shock to the roots and, being unable to produce new ones quickly enough, die, practically of starvation and drought.

Many roots have root-hairs. These are developed chiefly on land plants to assist in obtaining water more quickly from the soil. In water-plants root-hairs are usually absent. But the roots of such plants (*e.g.* the Watercress) grown on land soon develop root-hairs.

From the above remarks it is obvious that one of the chief things necessary to enable roots to perform their work properly is water. Without moisture in the soil the roots are useless, and the entire plant collapses in consequence. From a gardening point of view, therefore, the greatest attention should be paid to the watering of plants, some requiring more and some less, according to their nature. Whether the water which is absorbed contains plant food or not depends a good deal upon the operations of the gardener. It is possible that many of the foods referred to at p. 70 are in the soil, but they must be readily soluble in water, and also be in a fit state to benefit the plant.

Besides the substances absorbed in the water, root-tips and hairs absorb substances otherwise insoluble in water, and cling tenaciously to particles of minerals. They exude an acid secretion which dissolves the mineral matters, and these are thus modified so as to become digestible, and readily pass through the cell-walls into the protoplasm referred to above.

Root-pressure.—It is well known—indeed obvious—that the tallest tree in the world has water drafted to its highest point. This is an extraordinary fact when it is remembered that the Giant Sequoia of California and the Gum Trees of Australia often reach the great height of 400 to 500 ft. The tips of branches being naturally the youngest and tenderest parts of a plant are always well supplied with water. How the water gets to the outermost tips is a debatable matter and many theories have been suggested; but the fact remains that it gets there, and the propelling force has been termed ‘root-pressure.’ It is supposed that the water from the fully charged lower cells diffuses or filters through the partitions or walls into the upper cells by a process called ‘osmosis,’ referred to above under the chapter on ‘Growth.’ It can hardly, however, be a mere physical process, as each living cell in a plant contains the living substance called protoplasm already referred to. As each cell containing protoplasm is more or less supplied with watery juice from the roots, it is evident that a vast quantity of moisture is thereby taken from the soil, and passes from cell to cell by root-pressure. When trees and shrubs are cut in spring during the period of great absorption, large quantities of water are sometimes forced from the cut surfaces, and constitute what gardeners call ‘bleeding.’ This, if carried to excess, would be injurious, if not fatal, to the plant; but the surplus overflow as a rule soon becomes checked by the development of fresh leaves, the cells of which must be supplied with sap, and serve to stop the overflow from any wounds.

Kinds of Roots.—Roots, while all performing the same functions, differ a good deal in appearance. Broadly speaking they may be classified as *fibrous*, *fleshy*, and *tuberous*. All grasses and many annuals, biennials, and herbaceous plants have fibrous roots, while the Dahlia may be taken as an example of a plant with fleshy roots. What are termed ‘adventitious’ or accidental roots are those developed from any part of the plant except the seed. The roots of cuttings, layers, stems, &c. are therefore all adventitious. In the case of Monocotyledonous plants (see p. 127) the primary root from the seed soon ceases to grow, and all the roots afterwards developed are from the stem, and are hence mostly adventitious. Their functions, however, are precisely the same as those of the true roots developed directly from the seedling.

The tubers of Potatoes and Jerusalem Artichokes, the rhizomes or rootstocks of Irises, the corms of Crocuses and Gladioli, and the bulbs of Onions and Lilies, although all naturally growing in the soil are not really roots at all but modified stems, and are referred to below.

THE STEM

The stem is the axis of the plant which bears leaves, flowers, and fruit so that each shall be in the most favourable position for performing its functions. The leaves are separated from each other by greater or less distances called internodes. Sometimes these internodes are so short that the plant appears to be stemless or almost so, as in the Primrose and Houseleek. Stems always originate in a bud, the first one arising between the seed-leaves from the small bud known as the *plumule*. Branches arise also from buds in the axils of leaves, and this gives the spreading habit so characteristic of trees and shrubs, all belonging to the Dicotyledonous and Gymnospermous groups of plants (see p. 122). Among the Monocotyledons (p. 127) and Ferns (p. 1008) buds at the end of the stem only are developed, hence the usually unbranched character of their stems.

In the lower orders of plants, such as Seaweeds, Liverworts, Mushrooms &c., stems are unknown. The first trace of a stem appears in the Mosses, and becomes more marked in the Clubmosses (p. 1024), Horsetails (p. 1023), and Ferns (p. 1008); but the stem as generally understood attains its greatest development in the plants belonging to the flowering groups, as seen in the Oak, Apple, Beech, Elm, Pine &c. Whether they are herbaceous, that is, soft, tender, and deciduous as in annuals and biennials (p. 78), and herbaceous perennials (p. 86), or woody as in trees and shrubs (p. 107), the stems of all flowering plants have their origin in the 'plumule' or first bud of the embryo plant.

STRUCTURE OF STEMS

Besides the differences in stems referred to below, it may be mentioned here that there is a very marked difference in the structure of the stems of Dicotyledonous plants (p. 122) and those of Monocotyledons (p. 127). An examination of the stem of a Willow, Apple, Fuchsia, Wallflower, or any other plant belonging to the Dicotyledonous group will show in transverse section that it consists of three distinct parts, viz. (i.) the pith in the centre; (ii.) then the wood; and (iii.) the bark or rind outside. The bark is readily peeled off, especially when the sap is flowing upwards in spring, and it leaves the white wood exposed to view. On the outside of the wood and next the bark is a very important layer of quick-growing and actively dividing cells

called the 'cambium layer.' As long as ever a Dicotyledonous plant lives, this cambium layer has the power of doing two wonderful things: it adds by division of the cells a layer of wood on the inside every year, and a layer of bark on the outside, and it is by this process, which goes on year after year in woody stems, that the latter increase in bulk. It thus happens that the youngest part of the wood of a tree trunk is on the *outside* beneath the bark, and not in the centre near the pith; while the youngest bark is next to it and not on the extreme outer surface. It is the addition of a layer of wood each year to that already existing that gives the ringed appearance to tree trunks, each ring representing one year's growth.

If a strip of bark be taken off all round the trunk or branch of a tree without injuring the wood, it will be found that the leaves do not shrivel up or wither, as one might expect, as a result of the operation. It is evident, therefore, that the sap from the roots ascends by the vessels in the cambium and young wood, and not by means of the bark, nor yet by means of the pith or the old inner wood, as is indeed obvious when one sees a huge Elm, Willow, or Oak with all the interior scooped out of the trunk. It will also be noticed that, if a branch has a string tied round it firmly, the portion above the string will become swollen. This shows that the elaborated or assimilated food made by the leaves returns down the stem by the outer cells, and as these are compressed at the tie the descent of the nutritive material is checked at that point and the cells above become gorged.

There are many other kinds of cells and vessels in the stems of Dicotyledonous plants, some being spiral, like compressed watch-springs, some cylindrical with slits or holes in the sides, or only at the base where they join another vessel, and so on; and running through them all from the central pith or 'medulla' to the circumference are rays known as 'medullary' rays, popularly known as the 'silver grain' in wood.

All the cells and vessels in a stem are not of the same nature: some are very tender like those of the cambium, some tough like those of the bast cells, and others fibrous or woody. The latter are seen in the principal nerves or veins of leaves, and are gathered together into bundles. Each leaf is connected with the stem by means of these fibrous bundles, and as the leaves are arranged all round the stem it is obvious that the fibre-bundles from them collect and form a circle round the stem. The traces of these fibre-bundles from the leaf into the stem are well seen in the scars left by the fallen leaves in autumn, as in the Horse-Chestnut and other trees.

Such are briefly the main points in the structure of the stems of Dicotyledonous plants, and they are referred to here chiefly because a

knowledge of them is necessary for the operations of Budding and Grafting described further on.

In the stems of Monocotyledons we find a different structure, the most striking feature being the absence of real pith, wood, and bark. There is no cambium layer, and consequently no concentric rings of wood and bark as in Dicotyledons, and the fibrous bundles are chiefly collected on the outer portions of them, and give them the hard texture so well known in the stems of Bamboos and Canes.

As it is the presence of the cambium layer which enables grafting or budding to be done at all, it therefore follows that these operations cannot be performed satisfactorily on Monocotyledons which have no cambium layer in their stems.

KINDS OF STEMS

Stems are usually regarded as being above the soil, but there are certain modified kinds which perform their work beneath the surface, and are popularly looked upon as roots.

Those above the surface are classified as follows:—

1. *Herbaceous*. These are stems which die down to the ground every year after blooming, as in the case of most hardy herbaceous perennials (see list, p. 86).

2. *Sub-shrubby*, more or less woody below but herbaceous above.

3. *Shrubby, arborescent, or arboreous*, woody, and living from year to year, and attaining considerable size as in the case of trees and shrubs, a list of which is given at p. 107.

Stems assume various directions in growth, some being erect and ascending, others more or less trailing or prostrate on the ground, others creeping and developing roots at the joints, where they touch the soil; and others climbing or twining by tendrils, as in the Passion Flower and Virginian Creeper; by twisted leaf-stalks, as in the Clematis, or by aerial rootlets, as in the Ivy.

Stolons are stems or branches which recline on the earth and take root. Many plants are naturally increased in this way and the process of layering was no doubt suggested by seeing stems throw out roots when in contact with the soil.

An *Offset* is a short stolon with a tuft of leaves at the end, from which roots also develop, as seen in the common Houseleek.

Runners, as in the Strawberry, are similar in their nature, being long slender stolons which when fully grown develop roots at the tip, and afterwards buds and leaves to form a new plant.

Tendrils are branches modified for climbing purposes, and are either simple or branched, but are useless for propagating purposes.

Spines or Thorns are also modified branches or leaves; but the prickles of the Rose and Blackberry are merely excrescences or cellular outgrowths of the stem.

Underground Stems.—Perhaps the best known form of an underground stem is that of the Flag Iris (p. 917) and Solomon's Seal (p. 811). They look like real roots but the leaf-like scales and buds show them to be stems by nature. Many plants have underground and more or less creeping stems, as in Lily of the Valley (p. 813), Mint (p. 744), and Couch-grass, the latter on this account spreading rapidly and becoming a nuisance, especially when chopped by hoeing &c.

Underground stems are often thickened and serve as storehouses for food during the winter in many plants with herbaceous stems. They take many shapes, among which may be mentioned:

The *Tuber*, as in the Potato (p. 1133), the Jerusalem Artichoke, the 'eyes' of which are leaf-buds from which stems arise (p. 1140); the *Corm* or *Solid Bulb*, as in the Cyclamen (p. 626), Crocus (p. 936), and *Gladolus* (p. 947); the *Bulb*, as in the Madonna Lily (p. 846), the Tulip (p. 860), Hyacinth (p. 833), Onion (p. 1148) &c.

In some plants the stems are so modified in form and structure that they perform the functions of the foliage. The stems of many cactaceous plants are of this nature, and also the branches of the Common Butcher's Broom (see p. 810) which resemble leaves in appearance.

THE LEAVES

From definite points (called nodes or joints) of the stem and branches leaves are developed and arranged more or less horizontally, vertically, or drooping so as to obtain a greater or less amount of sunshine, and to throw water towards or away from the main axis of the plant, according to the nature of the species.

It will be noticed for example that the leaves of Rhubarb (p. 770), Arum Lily (p. 955) and other plants have the tips of the leaves uppermost. They are more or less channelled down the centre, and water is by this means transferred towards the centre of the plant, and down the stem to the roots. In such plants it will generally be found that the roots do not spread over large areas but are confined in a small space beneath the centre of the plant. Many other plants on the contrary, like most of our trees and shrubs and flowering plants, have the leaf-tips pointed outwards and downwards so as to throw the water chiefly around the circumference of the plant and away from the centre. In plants with these peculiarities the roots spread out and away from the

centre in all directions, and usually go beyond the circumference of the foliage. In this way the active fibrous roots secure the full benefit of the rain which is thrown off the leaves.

A complete leaf consists of a flattened portion, called the *blade*; a *stalk* or *petiole*, and a pair of more or less scaly or leafy appendages called *stipules*, all of which characters are illustrated in the Glossary at fig. 98. The stalk and stipules are frequently absent, leaving the blade attached to the stem by the base, when it is said to be *sessile*. As a rule, when fully developed, leaves cease to increase in length or breadth, and remain unchanged in form until death, when they are removed by natural decay, as in most Monocotyledonous plants (p. 127), or by breaking off at a joint, as in most Dicotyledons (p. 122).

Some leaves develop and die in one season, and are called deciduous; others persist for two or more seasons before falling off, new ones in the meantime being formed, thus giving the plant an evergreen appearance.

The tissue of the blade is traversed by a framework of stronger ribs or veins more or less netted in Dicotyledons, as shown at fig. 48 in the Glossary, p. 7, and parallel or curved in Monocotyledons, as shown at fig. 96 in the Glossary. The beautiful arrangement of the veins is well seen in leaves which have been skeletonised—that is, when the more perishable tissue (called *parenchyma*) between the veins has decayed through artificial or natural agencies. These veins serve not only to strengthen the leaf-blade, but also as channels through which the sap from the root is distributed to the cells composing the blade.

Structure of Leaves.—Ordinary leaves consist of an upper and under surface between which are layers of cells more or less irregular in shape and filled with grains of green colouring matter known as *chlorophyll* floating about in the protoplasm (see p. 22). The cells near the upper surface are much more compactly arranged than those beneath, hence the more intense green of leaves above. Where leaves receive an equal amount of light, as in Irises, Gladiolus, and many other Monocotyledons, there is not a great difference in colour between the two sides.

The skin, cuticle, or epidermis of the leaf is studded with small openings or breathing pores, known as *stomata*. These are more numerous on the under-surface, and it has been computed that there are as many as 60,000 of them to the square inch in a Lily leaf, and about 100,000 to the square inch on that of an Apple leaf. The leaves of water plants present a striking difference from those of land plants. Those under water are more or less divided and are so thin in texture that they

can absorb the necessary food or throw off surplus gases through the walls of the cells instead of through stomata. Those floating on the surface have stomata above, but none or very few beneath.

Functions of the Leaf.—The most important work of the leaf is to construct, manufacture, ‘elaborate’ or make digestible food for the plant out of the raw materials in the sap, and to give off through its pores surplus gases and watery vapour.

It is only under the light of the sun that the living protoplasm in the cells of leaves is capable of changing mineral matters and gases into plant food. From the air carbonic acid gas is taken in through the pores in the leaf and is absorbed through the cell walls by the protoplasm in the cells. The carbon is retained and the oxygen is given off. This process of manufacturing food is called *assimilation*, and may be likened to what is known as digestion with human beings and animals. By its means starch, sugar, oils and various other substances found in plants are obtained, and constitute the food of man and animals. The absorption and liberation of gases by means of the pores is known as *respiration*, owing to its being somewhat akin to the breathing of animals, the great difference, however, being that plants breathe out oxygen during the day instead of carbonic acid gas, and thus keep the air in a purified state.

Transpiration.—Almost every part of a living plant is continually giving off vapour from its tissues, although the quantity varies with atmospheric conditions. When in active growth the roots often absorb more water from the soil than is actually needed, and the surplus is given off into the air by means of the stomata in the leaves and minute pores in the stems. This continual discharge of watery vapour is known as transpiration, and according as the cells become emptied by evaporation they absorb fresh supplies from contiguous cells by means of the process already referred to as Osmosis, see p. 23.

Whether large or small quantities are given off depends a good deal upon the wetness or dryness of the atmosphere, and upon heat and cold—that is, practically on the state of the weather. It is not merely a mechanical process of evaporation, as the amount given off is regulated by the plant itself. When too much vapour is being given off, the stomata begin to close, as if realising that the loss of great quantities of water means injury to the plant as a whole. So long as the supply of water from the roots exceeds that given off by the leaves, the latter remain plump and fresh, as the cells composing them are turgid or full of watery sap. But as soon as the leaves throw off more water than is supplied by the roots, the cells of the leaves gradually become emptied

and collapse. As a consequence the entire leaf droops or, as gardeners say, it 'flags.'

In hot dry summers many thin-leaved plants may be seen to 'flag' during the day, although the roots may be well supplied with water, and only recover their freshness in the cool of the evening, when the transpiration current is not so great. This current of water from root to leaves continues as long as ever a particle of moisture remains near the roots. And it even continues for some time after plants and flowers have been severed from the roots and placed in water. This explains why in a cut state stems and flowers often last a long time fresh in water. If the base of the stems is cut from time to time, and under water if possible, the freshness may be extended for several days.

ARRANGEMENT OF LEAVES

Leaves are arranged upon the stem in definite order and may be *alternate*—that is, one after the other with only one leaf to each joint as shown in the Glossary, fig. 6; *opposite*, when there are two leaves to each joint, one on each side and opposite each other (Glossary, fig. 45); *whorled* or *verticillate*, when more than two leaves spring from a joint and form a circle (Glossary, fig. 116). In the case of Pine-trees it looks as if several leaves sprang from one joint, but such is really not the case: they are single leaves on a branch the joints of which are very close together.

The blade of a leaf may be in one piece, when it is called *simple*, as shown in the Glossary, figs. 4, 8, 10 &c.; or cut up into separate leaflets, when it is *compound*, as in figs. 17, 19, and 50 in the Glossary. Simple leaves assume roundish, elliptic, oval, or linear shapes with intermediate variations, and may be either sharp or blunt or slightly notched or pointed at the apex. The margins may be entire, wavy, serrate, toothed, lobed, or variously cut, and the base may be prolonged below the insertion of leaf-stalk, the lobes uniting and producing a peltate or shield-like form, as in the Indian Cress (*Tropæolum*) shown at fig. 79 in the Glossary. When the leaf-stalk (petiole) is absent the leaf is sessile, and when stipules are absent a leaf is said to be exstipulate. When the lobes of a sessile leaf are produced downwards to clasp the stem, leaves are said to be *amplexicaul*, as in fig. 8 of the Glossary; and if the lobes of opposite sessile leaves unite, they become *connate* as in fig. 33; or if single and surrounding the stem *perfoliate*, as in fig. 82.

Compound leaves may have the component parts called 'leaflets' radiating from the end of the stalk, as in the Horse Chestnut, when they

are termed *palmate* or *digitate* (Glossary, fig. 50); or from opposite sides of the midrib like a feather, when they are *pinnate* (fig. 85). The leaflets of pinnate leaves may be divided once, twice, or more times. When the leaflets arise from one another on each side of the middle lobe, they are called *pedate*, as in the Christmas Rose (*Helleborus*). There is great variation, and as a rule two or more terms are employed to describe the shape of a leaf, but the main forms will be found illustrated in the Glossary, pp. 1-18.

THE FLOWER

The botanist regards the parts of a flower as so many leaves specially modified for certain purposes. An ordinary flower is composed of (i.) sepals (the calyx); (ii.) petals (the corolla); (iii.) stamens (androecium); (iv.) carpels or pistil (gynoecium). The sepals and petals are often absent altogether: sometimes one, sometimes another. As a rule they form the most conspicuous and showy part of the flower, and their natural duty is supposed to be to attract insects to search for honey and thus disturb the pollen and fertilise the pistils or carpels. The stamens and carpels are the essential parts of the flower, without which it is impossible to obtain seed. The stamens contain pollen in the little sacs or bags at the apex called anthers shown at fig. 9 in the Glossary. Insects are useful in brushing this pollen against the sticky top (the stigma) of the pistil. The pollen is sometimes ripe before the stigma, and *vice versa*, and it thus happens that flowers are not often fertilised with their own pollen. In this way the pistils in one flower may be fertilised with pollen from another, and if the species are different a 'hybrid' has been effected, or a 'cross' if the plants are of the same species. Seeds obtained from a plant thus crossed do not exactly reproduce the characters of the parents, although the differences may be very slight.

Sometimes the same flower contains both stamens and pistil, when it is said to be *hermaphrodite*. When a flower contains stamens only or pistils only on the same plant, it is said to be *monœcious*, as in the Cucumber (p. 1156), Marrow (p. 1155), Begonia (p. 462). But when male and female (or staminate and pistillate) flowers are borne on different plants, they are said to be *diœcious*, as in the Aucuba (p. 475) and Willow (p. 802). Very often flowers are without stamens and pistils, and are termed *neuter* or *sterile*, as in the cultivated forms of the Guelder Rose (p. 480) and the Hydrangea (p. 429).

Double Flowers.—Cultivation often plays havoc with the stamens and pistils. These become more or less suppressed, and (as showing

them to be really modified leaves) they are replaced by petals, as in the garden Rose (p. 382), Carnation (p. 240), Hollyhock (p. 272), Double Begonia (p. 462) and Chrysanthemum (p. 531). The more the stamens and pistils become suppressed or modified by cultivation, the less chance is there of obtaining seeds from such flowers, and plants bearing them are with difficulty increased by seeds. Hence the adoption of other methods of propagation in such cases.

FERTILISATION AND HYBRIDISATION

Since the functions of the stamens and pistils have been better understood, gardeners have taken full advantage of them by transferring the pollen from the stamens of one flower to the pistils of another with a view to raising new races or 'strains' as they are called. When in a reciprocal state, fertilisation is usually effected, the pollen grows on the sticky surface of the pistil (called the stigma) and seeds are ultimately borne in the way described at p. 24. The plants raised from such seeds may combine the characters of both parents in a more or less even degree. When two species of the same genus are thus fertilised a 'hybrid' is the result. When two species belonging to different genera are fertilised, the product is called a 'bigeneric' hybrid. But when forms of the same species are fertilised with each other, they are simply called 'crosses,' and chiefly differ in the colour and size of the flower.

Of late years hybridisation has been carried on to an enormous extent among all classes of plants, and some very fine garden flowers have been thus obtained. It must be remembered, however, that only plants having a natural relationship to each other are likely to produce hybrids. The more distantly related they are, the less likely are they to be fertilised or produce seeds. As most of the plants described in this work are arranged according to their natural relationships to each other, it will be easy to see which are the most likely ones to use for hybridising purposes.

Unlike animals, it is a remarkable fact that most plant hybrids are capable of producing fertile seeds, and are as perfect in every detail as the species from which they were originally derived. Occasionally a hybrid is met with, which only with difficulty can be fertilised and made to produce seed. In such a case as with 'double'-flowered plants it must be increased by other means than seeds.

It may be appropriate to mention here that certain flowers, like Primroses (p. 617), Auriculas (p. 618), Oxalis (p. 292), Loosestrife (p. 451) &c. have the stamens and pistils alternately long in some flowers and short

in others, and Darwin has pointed out that pollen from long stamens in one flower is naturally adapted for fertilising the long pistils in another; and the same with the short forms. Many flowers are fertilised by bees and various insects, but many others, like the Pine trees (p. 972), Willows (p. 802), Alders (p. 796), Poplars (p. 803), Birches (p. 793) &c., depend upon the wind to have their pollen blown about and transferred to the ovules (as in the Pines) or pistils (as in the others).

FORMS OF FLOWERS

Flowers are usually said to be 'regular' when their sepals and petals are similar as shown in figs. 24, 40, 54, 59, 63, and 66 in the Glossary; or 'irregular,' when one or more sepal or petal differs in size or shape from the others as shown in figs. 5, 22, 23, 58, 60, and 67. The petals may be quite free from each other, when they are called *polypetalous* (see p. 122), or may be united, when they are said to be *gamopetalous* (see p. 125). In the Glossary figs. 23, 24, 59, 63, 65, and 67 are examples of Gamopetalous flowers, while figs. 5, 40, 54, and 58 are examples of Polypetalous flowers. The stamens and pistils may also be either free or united. These characters are of great use for the purposes of classification, and are more systematically detailed at p. 120.

THE INFLORESCENCE

The way in which flowers are borne is termed the inflorescence. Flowers may be at the ends of the branches or in the axils of the leaves, and may have stalks (peduncles) branched or unbranched forming racemes, panicles, corymbs, umbels, or cymes &c.; all of which terms are explained and illustrated in the Glossary (p. 1). When without stalks they may form spikes, as in the Plantain, or heads, as in Clover, or catkins, as in the Birch. There are various modifications of these, as in the Arum Lily, where the flowers are in a fleshy spike (*spadix*) enveloped in a large and showy leaf called a *spathe*.

THE FRUIT

In popular language the term 'Fruit' is very vaguely used. Strictly speaking, the ripened carpels, whether hard or soft, constitute the fruit, or, in other words, the seed vessel or ovary. All flowering plants which produce seeds enclosed in an ovary are termed *Angiosperms* (see p. 121) and include both Dicotyledons and Monocotyledons.

The Pine trees and Cycads have their seeds quite naked on scales, and are termed *Gymnosperms* (p. 122).

Development of the Fruit.—Soon after the stigma of a carpel has been fertilised it withers, and the ovary begins to enlarge, the ovules which it contained now developing into seeds as the result of fertilisation. Sometimes an ovary (or fruit) contains only one seed, sometimes many, and there may be many ovaries in one flower, as in the Strawberry (p. 1089), Raspberry (p. 1085) &c., each containing only one seed; or there may be few ovaries or only one, each containing several seeds. In any case the ovary consists of one or more carpels either separate and distinct, or united.

When ripe, some fruits open naturally and shed their seeds, and are said to be *dehiscent*; others never open, and the seeds are only liberated by the rotting of the ovary walls. Such fruits are called *indehiscent*. As many kinds of fruits are mentioned in the pages of this work it may be as well to briefly define those best known.

SOFT OR FLESHY FRUITS

The *Berry* is a fruit which is soft throughout, the seeds being imbedded in a pulp, as in the Gooseberry (see Glossary, fig. 14), Currant, Grape, Tomato, and Orange (the latter having a leathery rind). The *Pepo* or *Gourd* is a hard-skinned berry, such as the Cucumber, Marrow, Melon.

The *Pome* is a fleshy fruit like the berry, but the calyx is the thickened edible portion in which is imbedded the cartilaginous ovary known as the 'core' in Apples, Pears, and Quinces (see Glossary, fig. 88).

The *Drupe* is the name of the fruit of Cherries, Peaches, Plums, Almonds and Nectarines. The outer layer, often merely the skin, is called the *epicarp*; the middle layer or flesh the *mesocarp*; the inner layer or 'stone' the *endocarp* (see Glossary, fig. 52)

In the Blackberry and Raspberry the fruit consists of a collection of small drupes and is called an *etario*. The fruit of the Mulberry, like that of the Blackberry in appearance, is the product not of one flower but of several crowded on a short stalk.

HARD OR DRY FRUITS

The *Achene* is a small dry indehiscent one-seeded fruit, well seen in Buttercups and Strawberries. In the latter they are popularly regarded as 'seeds.' The juicy edible pulp is in reality the swollen top or receptacle of the flower stalk (see Glossary, fig. 1).

The *Pod* or *Legume*, familiar in the Pea, Bean, Scarlet Runner &c., is a fruit splitting into two valves, bearing the seeds on the edges (see Glossary, fig. 69). A *Lomentum* is a pod constricted between the seed breaking transversely into distinct joints.

A *Samara* or *Key Fruit*, like that of the Elm, Ash, or Maple, is an indehiscent fruit furnished with wings (Glossary, fig. 97).

A *Follicle*, as seen in the Pæony, Larkspur &c., is a simple carpel opening on one side only (Glossary, fig. 57).

The *Capsule* is a dehiscent fruit composed of more than one carpel usually with many seeds (Glossary, figs. 26, 27).

The *Siliqua* and *Silicle* are the long and short pods respectively of the Crucifer order (p. 201) (Glossary, figs. 99, 100).

The *Cone* is the peculiar multiple fruit of the Pine-tree family (p. 972). The cones consist of flat scales overlapping each other, and bearing the seeds at the base (Glossary, fig. 106).

The *Cremocarp* is the name of the fruit of the Umbellifer family (p. 464). It consists of two achenes which split apart when ripe (Glossary, fig. 38).

A *Nut* is a dry indehiscent fruit usually with one seed surrounded by a bony wall, as the Hazel or Cobnut (p. 797). In the Oak, the nut or acorn is fixed in a cup called the *cupule*, the whole fruit being called a *Glans* (Glossary, fig. 61).

INFLUENCE OF LIGHT ON VEGETATION

All plants having green leaves or stems can only properly develop and perform the function of assimilation or digestion by the aid of sunlight. Mushrooms (see p. 1166) and other Fungi carry out their functions with and without the aid of light. Some plants like as much sunlight as possible; others only a little, preferring a diffused light or deep shade; and others again seem to thrive better under intermediate conditions, some leaning towards light rather than shade.

Light is essential in any case to secure the formation of *chlorophyll*, the name given to the green pigment found in the cells of leaves. But this substance also requires a suitable temperature, and will not develop in very cold weather. The absence of chlorophyll is noticeable by the pale or yellowish appearance of the plants.

Sometimes gardeners are not anxious that it should develop at all; hence the reason of blanching Celery (see p. 1130), Seakale (p. 1121) &c. by covering the leaf-stalks over with soil, pots, boxes &c. The exclusion of light prevents the formation of the green colouring matter, and the stems are in consequence more palatable when eaten.

In the absence of light the leaves will not absorb carbonic acid gas, which is essential to the welfare of the plant. The latter must therefore live on whatever reserve material it has stored away in the stems or roots.

All observant gardeners know the difference between plants grown in light and plants grown in darkness or deep shade. Those under the latter conditions grow rapidly, and plants that are naturally sturdy will assume a weakly, more or less climbing habit, being anxious to reach the sunlight. And every cottager knows that the leaves and shoots of the 'Geranium' in his window always turn towards the glass and not towards the centre of the room.

On the other hand plants grown in plenty of light do not develop so rapidly, but each part performs its own function properly and steadily, with the result that the plants are more sturdy, and the stems and shoots become better matured and produce better flowers and fruits.

Light may therefore be said to have a dwarfing and ripening effect upon plants, while darkness has an elongating and weakening effect.

Apart from this may be mentioned the fact that the leaves of many plants of the Leguminous order (p. 322), such as the well-known Sensitive Plant, go to 'sleep'—that is, droop—during the night time, and only regain their spreading position in daylight.

From a cultural point of view, therefore, it is important to notice the effect of light, shade and darkness in plants. Very often a plant which has been grown in strong sunlight will not thrive under the best of treatment; but when it is shaded or partially shaded, it soon begins to show that it appreciates the altered conditions by the way in which it puts forth new growths. At p. 88 a selection of plants is given which will flourish in shaded or partially shaded situations, while many others are mentioned in various parts of the work.

PROPAGATION OF PLANTS

PROPAGATION is the term applied to any method by means of which plants are increased or multiplied in number. Some plants can only be increased in one way, others in several; but as a rule the gardener usually and not unnaturally selects the method which gives him the quickest and what he considers also to be the best results. In the case of annuals and most biennials (see p. 78) he has no other choice as a rule but to raise them from seeds. This is also Nature's method of

increasing most plants, but the process is often too slow to be regarded with satisfaction by the gardener. He therefore also has recourse to the other methods of propagation described below.

I. Propagation by Seeds

As just stated above, most plants growing in a natural state are increased by seeds. From a garden point of view, however, it is not always advisable to adopt this means, although many hundreds of plants may be very easily raised thereby. When it is desired to keep any particular plant true to its variety—that is, so that the progeny may faithfully reproduce all the features of the parent, in regard to habit, foliage, flowers, colour, fruit, flavour &c.—it is not wise to increase or propagate such a plant by means of seeds. For this reason: that pollen from the flowers of an inferior, or at least undesirable, variety may have fertilised the pistils in the flowers of the plant which it is desired to propagate. The characters of the original variety would in this way be tampered with, and the seedlings, although very similar to it, may have inherited some of the undesirable qualities of the strange parent, and lost the most desirable ones of the other.

It is therefore almost impossible for any seed to reproduce all the characters and qualities of its mother parent with absolute fidelity. Where little or no importance is attached to this fact, seeds will be found one of the readiest methods by which large numbers of plants may be produced. Plants raised from seed offer immense variety, and where novelties are required either as hybrids or crosses (see p. 37) it is a most interesting occupation raising them from seeds.

SEED SOWING

The best time for sowing seed is either in the autumn when thoroughly ripe, or in spring, when the earth's natural heat is favourable to germination. In a state of nature, as soon as seeds are ripe they fall to the ground and perhaps remain dormant during the winter, or else germinate sufficiently early to be strong enough to withstand the rigours of winter. All our annual weeds and a good many of our choice hardiest annuals if left alone would reproduce themselves in this way. And so would the hardy biennials and perennials, as witness the Evening Primrose, Horse Chestnut, Ash, Oak, &c. From a gardening point of view, however, it is found convenient to make spring the chief seed-sowing season, as there are so many other matters to attend to in the autumn. Other periods, when preferable for any particular plant, will be found noted in the following pages.

PREPARATION OF THE SOIL FOR SOWING SEEDS

Seeds are sown out of doors, either in beds, or in rows or 'drills' as they are often called. In whatever way they are sown the ground must first of all be specially prepared for their reception. It should as a rule be well dug or trenched some time previously, so that it will have had sufficient time to settle down afterwards. The surface must be made fine, and should be quite free from clods or lumps. As a rule seed beds are level, but they may under certain circumstances, where the soil, for instance, is naturally heavy and wet, be raised, with alleys about a foot wide between them, the better for thinning out, weeding &c. afterwards. Under south walls, the beds may be slightly inclined so as to catch more benefit from the sun's rays in early spring. The soil being thus warmed naturally excites growth, and the seedlings appear rather earlier than if sown under other conditions.

The necessity for a fine surface is obvious when it is remembered that the seeds of a vast number of plants are very small. If the soil were in a rough state and somewhat lumpy, the small seeds would sink down much too deep, and the young plants would probably never see the light of day; or if they did it would be in such a weak and exhausted state that they would recover only with very great difficulty.

The upper surface of the soil may be made fine in various ways. It may be sifted and afterwards levelled with a rake; or, if it is in a good friable condition, any lumps in it may be readily crushed with the spade or fork, before levelling properly with the rake.

The soil also may be trodden down well with the feet or a very light roller. This will secure evenness and consistency throughout, and will afford a much better run for the roots than if it is left very loose and powdery.

COVERING SEEDS

There is a vast range of variation in the size of seeds—some being like dust and scarcely discernible, while others, like the Pea, Bean, Horse Chestnut &c. are large enough to be handled quite easily. The well-known seed of the Coco-nut Palm is one of the largest seeds known, while those of our British and exotic Orchids are among the very smallest. Similar to these latter are the spores or 'seeds' of Ferns, while those of Rhododendrons, Azaleas, and many other plants of the Heath order (p. 574) are very little larger. Such a difference in size naturally suggests a difference in treatment in regard to covering seeds. The rough and ready principle usually adopted is to cover seeds with soil equalling their own depth or diameter, and for all practical purposes this is found to work very well. Minute seeds,

like those of *Rhododendron*, therefore, are simply sown on the surface of the prepared soil, the fineness of which should as a rule correspond to the fineness of the seeds sown. Larger seeds may be covered with soil to a depth varying according to their size.

WATERING SEED-BEDS

Water is just as essential to growth as heat. Hence the soil in which seeds are sown must be in a more or less moist condition according to the nature of the plant. Some seeds require to be moderately moist, while others—such as those of marsh plants, a list of which is given at pp. 112, 113—require to be sown almost or quite in a wet muddy soil. In the case of the fine seeds already alluded to, where there is no covering of soil, great attention to watering is necessary for some time. Being not only minute, but also tender and likely to be shrivelled up by drought, the soil on which these tiny seeds rest should before sowing be thoroughly soaked with water. Afterwards they may be kept moist with a sprinkling from a very fine-rosed watering-pot, or the pots or pans in which they are sown may be stood half their depth in water. In this way the soil will absorb moisture upwards from the bottom, and thus avoid the necessity of watering with a can. Very often, when the latter is used carelessly or thoughtlessly for fine seeds, these are washed into a heap at one side, and thus are too dense to permit any good growth in the seedlings.

RECEPTACLES FOR SOWING SEEDS

It is often more convenient to sow seeds in greenhouses, hotbeds, or cold frames; or the quantity to be sown may be so small that it is not worth while sowing it in the open border. Under such circumstances flowerpots, pans, or shallow wooden boxes are generally used. Whatever receptacle is used it is first of all necessary to see that it is well drained before filling it up with soil.

'CROCKING' OR DRAINING POTS

In the case of flowerpots, these must be 'crocked,' as gardeners say. A flattish piece of broken pot, having about the same diameter as the bottom of the pot, is placed over the hole in the centre. Over this large 'crock' smaller ones are placed, sometimes as much as half way up or more, when particularly good drainage is required. Where large quantities of crocks are used, they should become gradually smaller towards the top. Over them all is placed a layer of moss, or fibre of some sort,

such as that shaken out of peat, or turfy loam. This prevents the soil from being washed down among the crocks, and thus choking up the spaces between them required for the free passage of water and air.

NECESSITY OF DRAINAGE

Too much importance cannot be attached to the proper drainage of soil, whether it is held in a pot or box, or whether it is in the open garden. Unless the water can pass away from the soil readily, it becomes more or less stagnant in it, causes sourness, prevents the circulation of air, lowers the temperature round the roots, and generally interferes with the health of the plant. Under the chapter on soils the question of drainage is more fully treated (see p. 66). Whether boxes, pans, or other receptacles are used, the question of drainage must be first attended to as with flowerpots.

Having attended to the drainage, the soil, which must be of a nature suitable to the plants to be grown, may be placed over the moss and crocks, and pressed down more or less firmly with the fingers or a small piece of flat board, and brought to within half an inch of the top of the rim as a rule. Where very fine seeds, like those of *Begonia*, are to be sown the soil may be raised in the centre, forming a shallow dome, but in such cases the soil must be light and easily permeable by water.

HOW TO SOW SEED

As a general rule, it may be said that seeds of all kinds of plants are sown too thickly, with the natural consequence that the seedlings spring up very close to each other, and if they are not 'pricked out' or 'thinned out,' as described below, they soon stifle each other, and very few, if any, good plants are obtained.

Where the seeds are fairly large and easily handled there is no excuse for sowing them thickly. It may take a little longer time to sow them at more or less regular intervals, but the time spent then will be saved, and more than saved, later on when they have germinated. In the event of other work requiring attention, thinly sown seedlings may be allowed to stand longer in the seed-pots without injury than those which have come up too close to each other.

With tiny seeds it is very difficult to avoid sowing them thickly, and great care must be exercised in handling them. Some of them are so small and so light, that hundreds of them may be blown away and lost for ever by a slight puff of wind, or even a cough. Such seeds therefore should not be sown in a draughty place for this reason.

To avoid sowing them too thickly, it is a good plan to sift some dry sand through fine muslin or a hair sieve, and mix the seeds thoroughly with it. The sand and seeds may then be sown as thinly as possible over the surface, treating the grains of sand as if they were seeds—and the seedlings will as a rule not be so close together as if sown without this artificial aid.

The sowing of Fern spores has been dealt with separately at p. 1008.

THINNING OUT SEEDLINGS

This will be necessary when the seedlings are large enough to handle, so that those intended for bloom will have ample space to fully develop without having had their roots disturbed. Thinning out is best done in dull showery weather when the seeds have been sown in the open air. Failing this, the seed bed should be watered before or after the work.

PRICKING OUT SEEDLINGS

This operation is almost equivalent to thinning the seedlings and to transplantation. It consists in transferring the seedlings from pots, pans, or places in which they developed from the seed, to similar receptacles or places, only much further apart according to kind. The plants have thus more room and air and become sturdy. They also produce more fibrous roots, as the removal usually injures the first central main or tap root, and its place must be taken by new fibrous ones developed from the sides.

Many plants are improved in growth by pricking out or transplanting, but a few are injured by the process, and these are mentioned in their proper places. As a rule it is safer not to transplant or prick out any plants which are grown chiefly for the sake of their tap-roots, such as the Carrot (p. 1128), Parsnip (p. 1129), Turnip (p. 1119), Radish (p. 1120), Beet &c. (p. 1151). If transplanted very young they may develop fairly regular-shaped roots, but as a rule they do not, hence are usually thinned out in the seed beds instead of being transplanted.

Hotbeds

As hotbeds and cold frames are most useful for raising seeds and for many other purposes in the garden, they may be referred to here.

A hotbed when well made is an extremely useful adjunct to a garden, and especially a garden without greenhouses. It may be erected in some out of the way part where its presence is not too noticeable. By its aid all kinds of tender plants may be raised in early spring or

protected in winter ; cuttings of bedding and other plants will quickly root on it, and many other uses may be found for it.

For making hotbeds the best stable manure should be used, together with plenty of leaves, those of the Oak or Chestnut for choice.

Stable manure by itself heats too quickly and dies out too rapidly. By adding leaves, heat is not generated so quickly but is more lasting and suitable for plants.

The whole should be well mixed and turned over (any dry portions being thoroughly wetted) every other day for about a week or so, to allow the rank steam to escape.

In making the hotbed, the litter and leaves should be placed evenly layer after layer, and in such a way as to be 6 to 12 inches longer and wider than the frame intended for it. As the bed proceeds it should be evenly and firmly trodden down, the better to secure a uniform heat. When finished and settled down the hotbed should be 3 to 4 feet high, sloping from the back to the front, and facing south. The surface may be covered with a layer of well-rotted manure, and upon this may be a covering of prepared soil or coco-nut fibre, varying in thickness according to particular requirements.

It is advisable to tilt the ends of the lights at first to allow the escape of rank steam. Shading may be done, if necessary, by mats, canvas, or whitening the glass.

When any plants described in this work require the assistance of a hotbed, the fact will be found mentioned.

Cold Frames

Besides hotbeds, cold frames are very convenient, more particularly for raising seeds of rather tender hardy plants, or for protecting perennial plants in winter that have been grown in the open air during the summer and autumn months. In very severe winters the frames may be banked round with litter, and covered with one or more layers of Russian mats if needed. In fine mild wintry weather the lights should be taken off or well propped up during the warmest portion of the day, when not frosty, and should be closed early enough to retain a fair proportion of sun heat for the night. Cold frames are of various sizes and makes to suit different kinds of plants ; but they are rather expensive. The amateur, however, can easily improvise a frame good enough for practical purposes. See page 100.

Labelling

After seeds of annuals, biennials, or indeed any plant, have been properly sown, it is important that each kind should be distinctly labelled. Wooden labels varying from 3 to 12 inches long may be

used. The surface should be slightly and evenly covered with white paint (Continental growers like yellow) and written upon while still damp. With the sharpened end of the label pointing to the left, the generic name should be written above the specific. The date of sowing should also be recorded, and to prevent it becoming obliterated by being pushed too far into the soil, this is best done on a space ruled off by a line at the top of the label. Several labels may be ruled at once, and there is nothing lost by a little neatness and clearness in writing. When special seeds are sown, the name of the sender, country &c. are worth while recording. Where many kinds of seeds are sown, it will be interesting to note how much longer it takes some seeds to germinate than others under equal conditions.

In the Flower Border and Rock Garden it must be admitted that labels often look far from picturesque, especially when the plants they represent have disappeared perhaps for ever. In such cases they have not inaptly been termed tombstones, and should be removed when all hope of the plant beneath the surface is abandoned.

On the whole, however, a good case can be made out for labels in the flower garden, whether of wood or zinc, especially when many species are grown, unless one has an extraordinary memory. In the case of deciduous herbaceous plants labels mark the spot in winter and prevent the plant being accidentally uprooted and thrown away. The size of the label, however, should always be more or less in proportion to the size of the plant, as nothing looks more ridiculous than to see a tiny plant an inch or two high hidden behind a label a foot long and 2-3 in. broad.

2. Propagation by Cuttings

Perhaps there is no operation in which the amateur gardener takes so keen a delight as in increasing any choice plant in his stock by the readiest means, and sometimes by unusual means, for the sake of experiment. Apart from increasing plants by the natural method of sowing seed, that of making cuttings is most popular, and many amateurs whose enthusiasm knows no bounds endeavour to make a new plant out of every part of an old one, whether suitable or not. As a rule, these enthusiasts make the best gardeners, as every failure is a lesson, and the more failures they can reckon the greater the extent of their knowledge.

Cuttings consist of detached portions of a plant—either root, stem, or leaves—from which separate and distinct plants with roots of their own are obtained, and lead an independent existence. Although some plants are more difficult than others to raise from cuttings, it may be

taken as a general principle that plants having buds, bark, and more or less pithy stems are capable of being increased by this means. This practically includes all the Dicotyledons except annuals (see p. 78) and excludes many Monocotyledons (p. 127) and Ferns (p. 1008). Plants are often increased by cuttings simply because there is no other way—but chiefly because seeds will not ripen or cannot be procured. Special varieties are also increased by cuttings, as, if raised from seeds, the distinguishing characters may be lost or blended with those of another variety, as already explained at p. 42.

Selecting Cuttings.—Cuttings should always be selected from healthy plants and the best varieties. When herbaceous, they are taken from the young plump shoots. A few of the lower leaves are stripped off, and the stem is cut away to a joint. Herbaceous cuttings may be put in whenever they can be obtained, but spring and autumn are perhaps the best seasons. If cuttings of choice plants are placed in a little heat, as on a hotbed (p. 46), and kept shaded for a few days, they root or 'strike' much more quickly than if left unprotected in the open air. But cuttings of a vast number of herbaceous plants and of trees and shrubs root easily in a shady border or in a cold frame.

Until a cutting makes roots of its own, it must continue to live somehow. It is well known that plants *with* roots will suffer from want of water, and that very hot sunshine will often cause the leaves to wither even when the roots are well supplied with water. How, therefore, is a piece of a plant which cannot absorb water, as it has no roots, and cannot prevent the evaporation of the moisture already in it, going to exist for any length of time, and not only exist, but produce roots and eventually develop into a large plant from which several other cuttings may be taken? It is well known that portions of plants placed in water often keep fresh and healthy for a long time, especially if kept shaded from bright sun. This fact is taken advantage of in regard to cuttings. They are usually placed in damp, sandy soil, and are kept shaded from the sun. Air is also excluded for a time. In this way evaporation is checked, the cuttings retain a good deal of their plumpness, and the cells of the cut surface when cleanly cut with a sharp knife have the power of taking up and transmitting from one to another a certain quantity of water.

The roots have still to be formed, otherwise the cuttings die, as they cannot live indefinitely in a rootless condition. In making cuttings they are usually cut clean across just beneath a joint with a sharp knife. The reason for this is that at every joint is one bud or more, usually in a dormant condition. These buds become plumper and plumper on the plant until they burst into leaf or flower. They evidently have the

power of attracting or drawing to themselves, therefore, a greater amount of nourishment than the part of the stem between the joints. When a cutting is severed just beneath this seat or storehouse of nourishment, the injured cells of the cut surface endeavour to heal their wounds and keep alive by drawing away some of this nourishment. When this takes place a cushion or ring is formed round the cut surface, and protects the inner cells from further injury. From this ring or cushion, which gardeners call the 'callus,' roots are soon developed—they are drawn out as it were by the moisture of the soil, and at once begin to absorb food in a soluble state at their tender tips. Once this stage has been reached a change is seen above the soil in the cutting. The young bud at the tip is no longer inactive, but begins to grow and put forth leaves, and these also begin to work in conjunction with the roots, and thus add to the size and weight of what is now an independent plant. Henceforth it must be treated like its parent and get the benefit of light, air, moisture and heat in the same way, according to its requirements.

A large number of plants may be obtained from cuttings, but there are also a vast number which cannot be increased in this way, such as 'annuals' for example. The same may be said of most biennials, that is, plants which take two years to fully mature before dying down. To these may be added such plants as Grasses, Bamboos, Palms, and many other plants like them having leaves with parallel or curved veins, and no rind or bark, as in the Willow, Apple, Pear, Plum &c.

Cuttings may be divided into two main groups—soft-wooded or herbaceous, and woody. In the Zonal Pelargonium, for instance, not only will the ends of the branches 'strike' or produce roots but almost every joint, always provided the stems are not too sappy. And here it may be as well to mention as a general rule that all cuttings should be taken from fairly well-ripened and firm parts of the plants. Cuttings of stems too young and watery are apt to rot very soon, and those from very old and dried wood do not root, chiefly because there are no young cells full of life left. Cuttings of most herbaceous plants and of many trees and shrubs all require pretty much the same treatment. They should be inserted in sandy soil, a hole having first been made with a blunt-pointed dibber about twice as thick as an ordinary lead-pencil. The soil should be pressed firmly but gently round the base so as not to crush the tissues, but at the same time firmly enough to prevent the cuttings coming out readily when gently pulled with the finger and thumb.

Pots, pans, shallow boxes, or any other receptacle may be used for putting the cuttings in, but whatever receptacle is used it should

always be well drained as explained under 'Seed Sowing,' p. 43. No particular heat is required for the plants mentioned, but in others which do not come within the scope of this work a very high temperature is necessary both above and below to make them throw out roots.

Cuttings of woody plants differ a good deal from those of soft-wooded or herbaceous plants. In them we have a quite different kind of cutting. The most notable thing is the absence of leaves, but dormant buds are shown at the joints where the leaves have fallen away. There are a large number of plants which are easily increased by cuttings of this kind. When the leaves have fallen off naturally in the autumn, the thoroughly ripened stems may be cut into various lengths and put into the soil, allowing them to remain during the winter. In spring the dormant buds will burst into leaf, and in the course of the summer new branches will be developed. All this is a sign that work is being done under the surface of the soil. Beneath the hard woody bark is a layer of green tissue, with a mass of green young cells full of the active growing material called protoplasm. During the winter the temperature has been too low to start the living matter in the cells into growth, and so they remain idle or dormant. But when the temperature reaches a certain point in the spring it happens to be just suitable for the protoplasm, and the contents of every cell in consequence become active. A 'callus' is formed at the cut end of the stem in the soil, and by-and-by young roots are developed exactly as in the soft-wooded cuttings, and the process of taking up nourishment from the soil begins in earnest. A large number of trees and shrubs, with net-veined leaves, can be increased in this way, among them being the Virginian Creeper, and its relation, the *Ampelopsis Veitchi*, which clings to walls, the Willow, Gooseberry, Currant, Mock Orange, Rose, Apple, Pear, Plum, Cherry &c. Of all these it is better to have a shoot about eight or nine inches long, so that about half of it may be inserted in the soil, although cuttings of many others need be only 2-3 in. long.

Root Cuttings.—Tops of branches and portions of the stems are the usual parts of a plant used for making cuttings. But there are other parts which are equally useful for the same purpose. The root, for instance, of some plants like the Japanese Windflower (*Anemone japonica*) and the Japanese Quince (*Cydonia japonica*), Sea Kale, the Rose, and many others, if cut into pieces a couple of inches long, and 'sown' in the soil as if they were seeds, will produce young plants. As a rule root cuttings are usually best put in a little heat. Only those plants the roots of which have a tendency to develop buds are increased in this way. A distinction must be made between these roots and underground stems.

Leaf Cuttings are employed in the case of plants in the *Crassula* order, and tender plants like *Begonias* and *Gloxinias*. The leaves are placed on fine sandy soil or coco-nut fibre, and the main nerves are cut through with a sharp knife. The sap from the cut surface forms a callus, and from this comes a little bud above and roots below. After a time the body of the leaves decays, leaving the plantlets, which are potted up singly into small pots, in fine rich sandy soil.

Preparing Soil for Cuttings.—The soil for cuttings should always be especially prepared, particularly for those of flowering plants. Whatever soil the plant grows in best should be used, with more than the usual mixture of sand; and it should always be well drained, as stagnant moisture would very soon rot the rootless stem. The more tender or difficult the plant, the more care should be taken in watering, shading, and airing the cuttings.

3. Propagation by Grafting

A graft is somewhat like a cutting, but instead of its being placed to root in the soil it is inserted in the stem of another living plant which is already provided with roots. Only trees and shrubs and sometimes herbaceous plants of the *Dicotyledonous* group can be grafted. The cut surface of the graft or 'scion' and the stock should fit neatly together, in such a way that the layer of the inner bark in each should be in contact. This layer is called the 'cambium,' and consists of thin-walled cells, which are always at work adding a layer of wood on the inside and a layer of bark on the outside, thus adding to the diameter of the plant stem, as already explained at p. 30.

FIG. 118.—WHIP GRAFTING.

FIG. 119.—WHIP GRAFTING.

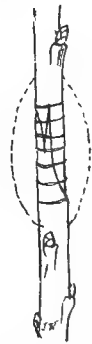

FIG. 120.—WHIP GRAFTING.

Varieties of Grafting.—There are various ways in which a graft is attached to the stock, the chief being :—

(a) *Whip Grafting*.—This is most generally practised. It consists in making an oblique cut in both stock and scion in such a way that they will fit exactly as shown in figs. 117 and 118. A tongue (T) is also cut in each so as to fit one into the other. Where there is a difference in size the scion must be inserted nearer one edge to secure the meeting of the inner bark. When neatly fitted, as in fig. 119, the whole should be bound with woollen thread or raffia so as to keep the scion from moving about, and clay or grafting wax should be at once plastered all round to exclude the air and prevent drying. Fig. 120 shows a completed graft tied up, the dotted lines representing the clay or grafting wax around the joined portions.

(b) *Cleft Grafting*.—This method consists in splitting or cleaving the head of the stock open by a chisel or small chopper. The end of the scion is cut wedge-shaped and inserted in the cleft so as to make the inner edges of the bark meet. This may also be called Market-garden Grafting, as it is usually employed in furnishing the tops of old, worn-out fruit trees. The objection to it is that in splitting the stock, perhaps in three or four places, a much larger space than is required for the scion is made, and may take a long time to heal, if it ever does. There are variations of this method.

(c) *Saddle Grafting*.—In this method the stock and scion must be of equal thickness. The stock, as shown in fig. 121 A, is cut upwards on two opposite sides to make a wedge. The scion, as shown in fig. 121 B, is split up the centre and hollowed so as to fit on top of the stock. The reverse method, of inserting a wedge-ended scion into the stock, is called *Wedge Grafting*.

(d) *Crown or Rind Grafting*.—This system is generally practised in spring, when the bark easily separates from the wood. The scion is cut obliquely, but a square shoulder is made at the base by a transverse cut. It is pushed in between the bark and wood of the stock until the shoulder rests on the top of the stock. Several slender grafts may be inserted by this means round the edge of a large trunk, as shown in fig. 122.

An improved method of Grafting is shown in figs. 123, 124, and 125. It is not exactly new, as something similar was practised about

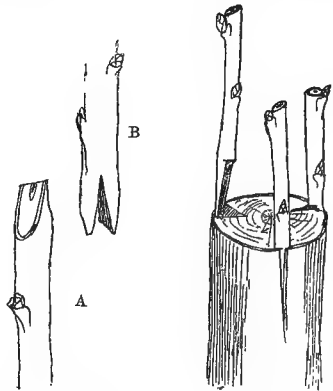

FIG. 121.—SADDLE GRAFTING.

FIG. 122.—CROWN GRAFTING.

ninety years ago ; but specimens from which the drawings were made were exhibited a few years ago in London to show the difference between the ordinary system of grafting and the improved one. Fig. 123 shows a graft inserted in a much thicker stock. The rind or bark, however, is not cut away from the graft, but is carried over the head of the stock, and is inserted under the bark on the opposite side. This is the only difference in the two operations, the tying up and waxing or claying being done as usual. The result of the union is shown, however, in fig. 124. This shows that a cushion of tissue and bark has formed over the head of the stock, and has thus protected it from decay owing to possible moisture, fungoid diseases &c. In fig. 125

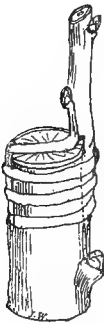

FIG. 123.

FIG. 124.

FIG. 125.

the result of inserting a graft in the ordinary way is shown. The union is perfect enough, but the central cylinder of wood in the stock has not been covered over by the bark, and is thus left exposed to the weather, and may sooner or later decay. This, of course, means danger to the graft, although it may not take place for several years.

(e) *Side Grafting* consists in inserting a graft sideways into the branch or trunk of a tree chiefly to fill up a vacant space. The scion may have either shooting buds on last year's growth and be inserted in April, or may have dormant buds on the current year's wood and be inserted about August or September, to develop the following year. The practise of inserting dormant fruit-buds has been tried in France and England, and the advocates of it claim that magnificent fruit has been obtained thereby. (See figs. 130, 131, p. 59.)

(f) *Veneer Grafting* is practised in spring or autumn, preferably the former, chiefly with evergreen trees and shrubs. The corresponding sides of the stock and graft are cut obliquely about 1 in. long, fitted together, tied, and placed in a close frame. The leaves of the scion are

not stripped off at the top, and the top of the stock need not be cut off till after the union has taken place.

(g) *Grafting by Approach or Inarching.*—This is rarely practised except on Vines. It consists in bringing the stems of two plants together, cutting away a portion of the bark of each, fitting the cut surfaces together and tying. Here both stock and scion have roots, but the scion is not severed from its parent until it has been completely united to the foreign stock.

(h) *Root Grafting.*—Many plants are grafted on roots of their own or an allied species, chiefly when the sap begins to flow in spring. Unless carefully performed the union will be imperfect and the plants useless after a time. Clematises were and still are grafted in this way, but sooner or later they nearly all die unless the operation is neatly performed, and it is therefore better to obtain plants from cuttings or seeds.

Whichever kind of Grafting is practised, the main point to remember is that the cambium-layers—seated just between the inner bark and the young wood—of both the stock and scion must come in contact with each other. It is useless placing the hard wood of the one against that of the other, as the cells in that portion have long ceased to be in a living state. The cells of the cambium-layer in the stock unite with those in the cambium-layer of the scion, the contents as it were intermix or fuse together by the reciprocal action of the protoplasm (see p. 22), and a union between the two is effected. As plants of the Monocotyledonous group have no cambium-layer it naturally follows that they cannot be grafted; but notwithstanding this, numerous attempts have been made, and all have failed.

Selecting the Grafts or Scions.—In selecting a branch for grafting due consideration must be given not only to the relationship existing between stock and scion referred to in the preceding paragraph, but care should be taken to select well-ripened shoots of the previous year containing several buds. Attention should also be given to the buds to see that they are leaf-buds and not flower-buds. The main object in grafting being first of all to produce branches, it is obvious that this may be effected more readily by means of shoots having leaf-buds instead of flower-buds. In the various fruit trees described in this work the difference between the wood or leaf-buds and the flower-buds is shown in the illustrations, so that readers may not mistake one for the other.

When grafting is practised only scions of really choice and fruitful varieties should be selected. The scions should be 6–8 in. long, and are best taken from the side shoots rather than those of the uppermost and strongest growing branches. It is not essential to unite a scion

to the stock immediately it is detached from the tree. Indeed, a few days are allowed to elapse so that movement of the sap shall become slower in the scion than the stock. The shoots, however, must not be allowed to dry or shrivel up, but may be placed in the soil in a shady place. If they are to be sent away any distance it is a good plan to stick the ends into a Potato tuber or moist clay, or to pack them in damp moss. When, however, the scion is about to be inserted in the stock the end should always be cut so as to have a fresh surface.

Time to graft.—Except where otherwise mentioned grafting is usually performed about March. About this time the sap is beginning to rise from the action of the roots, and the bark is more readily opened. The process of uniting also goes on slowly at first and becomes more rapid with the flow of the sap. The shooting of the buds on the scion usually indicates that union has taken place, and the ties should be looked at frequently afterwards, and loosened later on if necessary.

Relationship of Stock and Graft.—It is important to remember that plants cannot be promiscuously grafted one on another. They must at least belong to the same Natural Order, and should as a rule be closely related. As all the plants described in this work are arranged according to their close relationship with one another it will be easy to avoid making mistakes in grafting one species on to another with which it has no near affinity. It is improbable, for example, that a Barberry (p. 178) could be successfully grafted on an Apple tree (p. 1042), and *vice versâ*. At the same time such practices cannot be prevented, and if they *should* succeed it would indeed be a wonderful thing.

Exclusion of Air.—This is another essential point to remember when grafting. If the air is allowed to circulate around the cut surfaces the latter are soon dried up, a film is formed over them, and an effective barrier is thus placed between the cells of the two cambium-layers. Various composts are used to exclude the air, but those referred to below are perhaps the best and most generally useful.

Grafting Clay and Wax.—This is made of clay well worked up with a little chopped hay and horse or cow manure. If a hole is made in the centre of the heap, water poured in will keep it moist for a long time. It is an easy way of obtaining a good material for placing round grafts. In France a mixture of 28 parts black pitch, 28 Burgundy pitch, 16 yellow wax, 14 tallow, and 14 sifted ashes, is generally used instead of clay.

Three parts each of resin and bees-wax and two parts of tallow also make a good wax, which can be used lukewarm for grafts of small or delicate plants. The wax known as 'Mastic l'homme Lefort' is a clean preparation sold in tin boxes. It may be applied cold and is

called 'French Cold Grafting Wax.' Although soft, it hardens with exposure to the air.

ADVANTAGES OF GRAFTING

Some authorities condemn grafting altogether on the ground that the plants sooner or later lose their vitality and become little better than scarecrows. Where the operation has been unskilfully performed this is undoubtedly the case, but there are hundreds, if not thousands, of examples of grafted trees in the rudest vigour throughout the country. It seems as if the constitution of a plant goes a long way towards proving whether grafting is a success or a failure, and it is scarcely advisable to argue general principles from isolated examples on one side or the other.

It is claimed for grafting

(i.) That it increases and accelerates the fruitfulness in fruit trees owing to the check of the elaborated sap at the junction of the stock and scion in its downward course.

(ii.) That old and unfruitful trees with strong and healthy stems and roots may be rendered fruitful in two or three years by having scions of fruitful and healthy trees grafted on their tops.

(iii.) That naturally tall-growing varieties may be dwarfed by grafting on a less vigorous stock, and the reverse may also be attained. When there is too great a disparity between the stock and scion, the device of *double* or *treble* grafting is often adopted, so as to equalise matters as much as possible. That is, one or two kinds intermediate in vigour may be grafted on the stock before the required scion is ultimately grafted on to one of them.

(iv.) That a naturally deep-rooting tree, like the Pear, may be prevented from sending its roots down into cold and uncongenial soil by grafting it on a naturally shallow-rooting stock, like the Quince; and

(v.) That by means of grafting, choice varieties of fruit, the innate qualities of which cannot with any certainty be transmitted to their progeny by seeds, are preserved and multiplied with greater certainty and quickness,

· And in short space the laden boughs arise,
With happy fruit advancing to the skies.
The mother plant admires the leaves unknown
Of alien trees, and apples not her own.'

Influence of Stock on Scion.—It is curious that notwithstanding the growth of one species on another, and the influence exerted in regard to fertility &c., yet each kind undergoes no change in its

botanical structure. A Quince stock will produce Quince suckers, and the Pear grafted on it will produce only the leaves, flowers, and fruits of the Pear. In the same way, a Peach grafted on an Almond or a Plum will remain a Peach. While it is true generally that neither stock nor scion is affected by the other structurally, there is one remarkable exception afforded by *Laburnum Adami*, known as a graft-hybrid, and described at p. 327.

4. Propagation by Budding

The process of propagation by budding consists in detaching a ripened bud from one plant and inserting it beneath the bark in the stem of another closely related. It is confined almost entirely to woody Dicotyledons, for the same reasons as Grafting, viz. because they have a cambium-layer (see p. 30), and is usually performed about the end of May or June to the end of July, when the sap is in rapid circulation, and the bark readily separates from the wood. Almost all Roses, Stone-fruit Trees, as well as many ornamental trees, like Maples &c., are budded, and the practice is now being extended to many other trees and shrubs.

Budding may be done in various ways, but the method usually practised is known as shield or T-budding.

The bark of the stock should have a cut made lengthways and crossways like the letter T as shown in the sketch fig. 126. A bud is then carefully selected (in most cases care should be taken to select a leaf-

FIG. 126.

FIG. 127.

FIG. 128.

FIG. 129.

bud, not a flower-bud) by passing the knife behind the bud so as to secure a piece of bark or a 'shield' about $\frac{1}{2}$ inch long above and below it as shown in fig. 127, but without any wood behind. By allowing a leaf-stalk to remain beneath the bud, a handle is supplied, which enables one to easily insert the bud between the lips of the T-cut in the bark when gently pressed open by the thin bone handle of the budding-knife. The bud must then be carefully and firmly—but not tightly—tied with woollen thread or soft matting, gently bringing the edges of the cut together. In a month or so the bud will have begun to swell, and the thread or matting if not already burst or

decayed should be loosened or removed altogether. Fig. 128 shows the bud inserted halfway in the slit, and fig. 129 shows it completely inserted and securely tied.

About November the budded shoot will have grown a good deal, and should be cut back to within 5 or 6 inches of the insertion of the bud; in the following March or April the shoot may be still further shortened back close to the bud itself before growth commences.

Where much budding is done, care must be taken to keep the buds from being dried up by the sun and air. A good plan is to have them in a jar or water-pot with some wet moss to keep them fresh.

Budding is often performed later in the season than August, with the object of keeping the bud from shooting until the following spring. It is also done in spring just at the beginning of growth, but the same principles underlie the operation no matter when performed. Sometimes a dormant

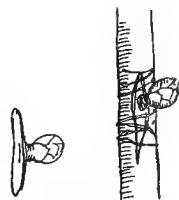

FIG. 130. FIG. 131.

fruit-bud as shown in figs. 130, 131 is inserted in autumn, and is said to produce larger and finer fruits than the other fruit-buds.

5. Propagation by Layering

This operation is extensively practised to increase trees and shrubs, and perennial herbaceous plants which cannot be so readily propagated by other means. It consists in bending down to the soil a branch and fixing it by a peg (as shown in figs. 132 and 133), and covering it with a mound of earth (represented by the dotted

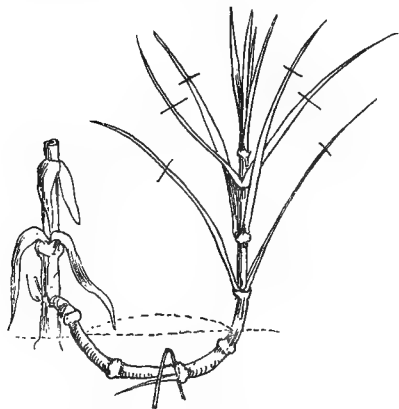

FIG. 132.—LAYERING HERBACEOUS STEMS.

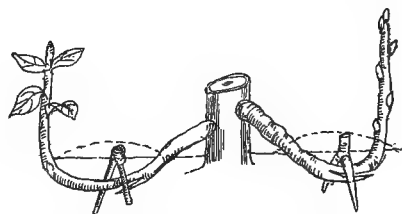

FIG. 133.—LAYERING WOODY STEMS.

lines) until such a time as it has developed roots of its own, the layer in the meantime being fed by the parent plant.

Very often the branch layered is cut halfway through lengthwise at the part to be placed in the soil, and a tongue or heel is formed, as shown near the pegs in the illustrations. The cut is kept open by the

soil, a small peg, or a pebble, and this induces a callus to form and roots to develop more quickly. Where the branches to be layered are near the ground, as in Carnations, Strawberries &c. there is little difficulty in performing the operation. Occasionally, however, branches of trees a few feet above the ground have to be layered. They must be carefully bent down, firmly pegged at the point of contact, and covered with soil. As a rule when the branches are fleshy or woody they may be notched or slit, but they are also simply twisted so as to bring the cells closer together at the twist, and thus arrest the downward course of the elaborated sap.

Principle of Layering.—Layering is practised on the principle that any injury which prevents or checks the return of the elaborated sap down the stem greatly facilitates the production of roots. This check is brought about by slitting the stem, removing a portion of the bark, notching &c. on the under side. As in a cutting, a 'callus' is formed on the cut surface by the returning sap, and roots are eventually developed.

Sometimes, instead of making an incision in the stems, a ligature of some kind, say wire, is bound round it tightly. This checks the return of the sap, and the stem above the ligature increases in size. If placed in the soil roots will be emitted, but if exposed to the air the effect in the case of fruit trees is generally seen in much larger and finer fruits.

6. Propagation by dividing the Rootstock

In the case of hardy herbaceous perennials (*i.e.* plants which live for several years, but the stems of which die down annually) dividing the roots in autumn or spring is found to be an easy means of propagation. The more carefully the work is done, the less injury is caused, and the sooner the plants recover. Chopping up with a spade in the case of Phloxes, Perennial Sunflowers, Larkspurs &c. is not to be recommended, as too much needless damage is caused thereby. Wherever shoots spring from the base or around the old rootstock they may be carefully detached either with the fingers or a sharp knife, and if inserted in good soil and kept shaded for a time, will produce good plants.

7. Propagation by Suckers

Many plants throw up from the root numerous leafy branches called suckers. It is often found useful to detach these carefully by means of a sharp knife or other instrument with as much root as possible attached. By transplanting to a shady place, they soon recover and are then practically established plants leading an independent life.

THE SOIL, ITS NATURE AND COMPOSITION

Soil is the term applied to the upper crust of the earth's surface which has been ground and powdered into a more or less fine state by the action of man and the weather. It consists of particles of various kinds of rock mixed with decayed or decaying animal and vegetable matters. Beneath the soil in which the roots of plants grow is what is termed the subsoil. This may be a bed of clay, sand, limestone, gravel &c., and is generally not in a condition to supply the roots of plants with the food they require until it has been tilled and mixed with the surface soil.

Soil absorbs and radiates heat and moisture and is gradually being broken up into smaller fragments by the action of heat, cold, moisture, and the gases of the air. Frost plays an important part in breaking down particles of rock and converting them into soil. The frozen water (ice) pushes the particles asunder and with the increase of temperature they fall apart. The absorption of heat by day and its radiation by night also reduce the soil to a finer condition. And the roots of plants themselves have the power of breaking up particles of rock, and even of dissolving by their action mineral substances not readily soluble in water. In fact a change is always going on in the soil, and the gardener simply hastens the process by his operations. It is as well, however, that he should always bear in mind that it is the upper layer of the earth's surface, and not that two, three, or more feet below it, that is likely to contain available food for the plants he grows. And although the under layers constituting the sub-soil may be broken up when occasion requires or opportunity permits, they should never be brought to the surface as a medium for the roots of plants to grow in.

Kinds of Soil.—Soils for gardening purposes are usually spoken of as sandy, clayey, loamy, peaty, chalky, and gravelly. A mixture of these is on the whole better than any one of them by itself; although for certain plants it may be better if one or other sometimes predominates.

Sandy and Gravelly Soils are of little value by themselves, but may be improved by the addition of clay, vegetable matter or humus and lime or chalk. By this means a loose gravelly soil is rendered more adhesive, and the roots are enabled to perform their functions without being torn about by the wind.

Clayey Soils are too sticky and retentive of water to be of any use to plants. They require to be broken up and mixed with sand, ashes, lime, humus, &c., until they are rendered sufficiently porous and at the same time capable of retaining moisture in the particles.

Loam is a well-balanced mixture of clay, sand, and humus, and is termed 'sandy' or 'clayey' according as one or the other predominates. For garden purposes a loamy soil is best, as it can be most readily cultivated to suit the majority of plants.

Chalky or Limestone Soils are those in which chalk or limestone is present in appreciable proportion, say over 20 per cent. The presence of lime may be detected by adding vinegar or any other weak acid to the soil. If the lime is present in any great quantity it will cause a froth, owing to the carbonic acid being released. Wet chalky soils are as bad as clay, but in a hard state the particles are of great benefit in keeping the soil open, and preventing the accumulation of noxious acids in it. For this reason lime (or strictly speaking carbonate of lime) is added to wet sour soils to drive off the carbonic acid gas, which is injurious. Peaty soils by its aid and good drainage may be rendered more or less fertile in time. Clayey soils by a similar process are brought nearer the ideal of what is required for the growth of plants.

Although lime is a great fertiliser of the soil and is always more or less essential in one form or another for a large number of plants, it is however injurious in the soil in which Rhododendrons, Azaleas, Kalmias and certain other plants belonging to the Heath family (p. 574) are grown.

Vegetable Soil or Humus contains an excess of organic material—that is, something which has been in a living state at one time either as plants or animals. This kind of soil, recognised by its dark colour, readily absorbs and retains water. It is useful for light sandy soils, which it binds more closely; and for heavy soils, which it renders more porous. It also has the power of retaining plant foods to a great degree, and by its slow decay or rotting generates carbonic acid gas, which is a powerful dissolvent of mineral matters in the soil.

Wherever organic decay or rotting takes place heat is generated, and this is well instanced by farmyard manure, leaves &c.; and when this heating process takes place in the soil, the latter becomes changed and rendered more fertile, and also warmer as a consequence of the fermenting processes which have taken place.

Humus, although very valuable, is not alone a suitable medium in which to grow plants, being too light, spongy and loose, and devoid of much mineral matter. It is most useful in conjunction with the other soils, and is chiefly obtained from farmyard manure, and the leaves of trees. The latter should be collected every autumn and stored in heaps. The action of the weather, rain-water, and an occasional turning over will soon reduce them to what is termed 'leaf-mould.'

In leaf-mould the gardener has a most valuable agent in rendering his soil suitable for the cultivation of plants. When well-rotted a little leaf-mould may be mixed with almost any soil used for the production of flowers, fruit, or vegetables, and some kinds are particularly fond of it as a rooting medium. Its use is frequently mentioned in the cultural operations in the body of the book.

IMPROVING THE SOIL

No matter how rich or how poor a soil may be, it can always be improved and rendered more fertile by various tillage operations. By digging or trenching the soil it becomes not only finer in texture and better mixed, but portions that were underneath before become exposed to the action of the weather—rain, frost, heat, cold &c., all of which produce important changes in it, making it as it were more digestible and acceptable to the roots of plants. Wet land cannot be successfully improved until means have been taken to drain away the water by furrows, ditches or pipes, or in the case of flower borders by having the bed filled with bricks, stones, rubble or some rough material through which the water will pass. An excess of wetness in the soil causes it to be cold, and the heat of the sun, instead of being used to promote the growth of the plant, is absorbed by the water. Stagnant water in the soil prevents the free access of air; hence acids are generated and bring about what is known as a sour condition.

Digging.—This is one of the most important and necessary operations for bringing the soil into a fertile condition. It is usually done with a spade or a fork, the object in view being to turn the upper layer of the soil completely upside down, so that what was underneath shall be exposed to the action of the sun and air, frost, snow, rain &c., and thus become more broken up and finer in texture.

Digging requires the exercise not only of physical strength but also of intelligence. Merely scraping the surface of the soil with the spade or the fork is not digging at all, and is of very little benefit, although to the uninitiated it may look quite as well on top as ground that has been properly dug. The object aimed at, however, is the improvement of the soil by crushing it, breaking it up, and completely inverting it. The spade or fork should therefore be driven straight down, almost at right angles, to the full length of the blade or tines, as the case may be, so that a good 'spit' or spadeful may be obtained. Where an odd man is employed for digging purposes it should be seen that he drives the tool straight down into the soil, as the more slanting the cut the quicker the ground is got over, and the less good is done to it. Where, however,

the owner of the garden can perform the digging himself it would be an excellent substitute for exercises such as rowing, cricket, lawn-tennis &c.

Best time for digging.—Ground may be dug whenever it is not in a wet sticky condition, and when free from frost and snow. During the autumn and winter months, however, the work is seriously taken in hand after the crops have been cleared from the ground. The fresh upturned soil is then exposed until spring to the action of the weather, and owing to the rest given and the chemical changes that have taken place, it will be in a much improved condition either for sowing seeds or planting out fresh crops.

How to dig.—The novice usually regards digging as a simple operation until he has tried his hand at it for half an hour or so. In that short period he not only secures a serious backache and can hardly stand upright, but he has also got into difficulties in disposing of the soil which he has been trying to dig up. Instead of having a clean open furrow always in front of him into which to turn the next ‘spit,’ he finds he has nowhere to place it except back in the spot from which he has lifted it.

To give some idea as to how the work is to be done, let the reader imagine this page to represent a piece of ground which is to be dug. If it is only a small area the first furrow—represented by the top line of type—may be taken out from the top and transferred to the bottom outside where the last furrow or line of type stands. Furrow (or line of type) number two may then be dug a spade deep and turned into the space left open by the first one taken out. And so on, digging each row from left to right or *vice versa*, and pushing it forward into the vacant furrow, until the last one is reached. The furrow here may then be filled with the soil taken from the first opening, and thus the whole surface will not only have been turned over, but will stand on a different bottom from what it did before.

Should the piece of ground be too large to dig across it at once, it may be divided into two or more convenient portions. Let the reader imagine it divided into two portions like some pages of this book. The soil from the first furrow—represented in the columns by the top line of type—may then be placed over at the top right-hand side or column. Then the various rows (as represented by the lines of type) may be dug one after the other as before until the end is reached. The workman then turns right about face to begin plot number two—as it were from the bottom of the page. The soil from the furrow (represented by the bottom line of type in the right-hand column) is transferred to the furrow at the bottom of the first plot on the left and thus completes it.

Plot number two is then dug in the same way as number one, until the top is reached. And here the soil taken out when the work was begun is used to fill the last furrow.

If the work is properly done, the surface, although perhaps cloddy, will be fairly even and be without hills and hollows. Before proceeding to dig each line or row, all weeds on the surface, and also manure, if any, should be turned into the bottom of the open furrow, after which the soil is placed upon it or them. The surface may be left as turned over, with the exception of any particularly big clods which are easily reduced with a slap of the spade or fork. If the surface is thus left rough for the action of the winter frosts and rains the clods will gradually fall asunder and by the spring the surface will be in a beautifully mellow condition, requiring only slightly forking over more for the sake of appearance perhaps than anything else.

Double digging.—As the name indicates, this means digging the soil two spits deep. The first spit is taken out in the usual way described above, but the subsoil is simply dug and inverted without being removed from its original position. This is an excellent practice where the subsoil happens to be rather poor. It also opens the soil better and allows the water to drain away more readily from the roots of the plants. And while it is better than ordinary digging it is not nearly so hard as trenching.

Ridging up.—This operation is performed by digging in a straight line and putting the soil from the furrow up on the left or right to form a ridge. The base of the ridge may be two spits wide and may have a spadeful of soil from a furrow on each side placed on top of it. Or it need only be one spit or spade wide, so that there shall be twice as many ridges and furrows, thus exposing more soil to the action of the weather. If the ridge on which the soil is placed has been dug beforehand it will be all the better. Ground thus treated may be left during the winter months to become mellowed and fertilised for spring cropping.

A modification of ridging is to turn up a spit and invert it in the same place. Then on top of this place the next spit, leaving a corresponding hollow. The ground treated in this way will be a series of little hillocks and hollows.

In the spring time, before planting, the ridges are forked down and made level, and it will be found that the texture of the soil has been wonderfully improved by the treatment.

Trenching.—This is a much more serious operation than digging, and is also far harder work. Consequently it is not done more often than is absolutely necessary. The work is usually performed at the

end of autumn or early winter. The object is to turn up a much greater depth of soil than can be accomplished by simple digging as described above, and to loosen and leaven the subsoil. As the latter, however, is generally much less fertile than the upper layer of soil, care must be taken that it does not completely replace that when the work is finished. Should it do so, more harm than good has been done, as the fertile soil has been placed at the bottom of the trench, where the roots cannot reach it; or if they do they have to work in a lower temperature, and this in itself may be detrimental to the roots. Unless they work in a proper temperature, the protoplasm (see p. 22) in the tender cells is unable to become active, with the result that water and the food it contains cannot be absorbed. Hence the leaves cannot assist in assimilating the food necessary to build up the tissues of the plants and to produce flowers, fruits &c.

Opening a Trench.—A piece of ground 3 to 4 feet wide should be marked off with a line. This is dug out about 3 or 4 feet—the width and depth of the trench usually correspond—and is wheeled to the other end of the ground, where the work is to finish. Indeed the work is laid out precisely in the same way as for digging, but there is of course much more soil to remove.

The first trench being open, the next piece of ground, the same width, is marked off and dug into it. The soil, however, should not be completely inverted as in digging, especially if the subsoil is poor, but should be placed in the trench in such a way that it is always more or less on an inclined plane. To secure this the soil from one trench may be allowed to invade the other, thus keeping the worst soil always at the bottom, and the best on top. Manure should be placed or mixed with the lower layers of soil, which in due course will become improved in texture and fertility.

Trenching may be repeated about every third or fourth year. But whenever it is done, the soil should, if possible, be trenched at right angles to the direction on the previous occasion, so as to secure greater distribution and change.

The same may be said in regard to digging. If the soil is dug from north to south on one occasion, it should be dug from east to west on another, or in any other different direction.

Drainage.—The necessity and importance of thoroughly draining the soil used in seed pots, pans &c. have been mentioned at p. 45. For the cultivation of outdoor crops, whether flowers, fruits, or vegetables, the necessity for a well-drained soil is no less important. Indeed the success of any crop depends very largely upon whether the soil is in such a porous state that water will readily pass away after

wetting it, and not remain in pools either on the surface or some little distance below it. Even in the case of plants which grow naturally in marshy or boggy situations stagnant water is injurious and means should be taken to prevent its accumulation.

Farmers are often obliged to drain their land by laying pipes at various depths, or by having trenches or ditches made at various intervals so that the water may be carried away from the soil in which their crops are growing. In the cultivation of flowers, fruits and vegetables perfect drainage is often secured by thoroughly trenching the soil, deeply digging it, and ridging it up as explained. I have seen neglected kitchen-garden ground so sodden with water that the surface became covered with the green slime so characteristic of stagnant moisture. But after it had been well trenched and left exposed during the winter months it became quite porous, and now bears good crops annually. The soil, therefore, cannot be turned up too much, and if the subsoil is too poor to bring to the surface occasionally it may be at least turned over as explained under 'Double digging.'

In wet heavy soil all the stones and rougher portions may be placed at the bottom to act as drainage much in the same way as 'corks' in a flower-pot. Flower borders very often require to be thoroughly drained with a layer of brickbats, clinkers, stones, mortar-rubbish &c. at a depth of three or four feet when devoted to the cultivation of certain plants, such as *Oncocyclis Irises* (p 918), *Mariposa Lilies* (p. 872) and other plants which readily succumb to stagnant moisture at the roots in our climate.

The reason why wet ground is so injurious to plant life is because the temperature is lower than in drained land, and the passage of air gases through the soil is prevented. As long as the soil is in a wet condition so long will the heat of the sun be used to evaporate the water instead of warming the soil. Even in the hottest summer, the warm water will come to the surface, while the cold will sink down and chill the roots and retard, if not altogether stop, their absorptive process as described at p. 27. And thus the plants suffer perhaps in the midst of an abundance of plant food which is not placed at their disposal in a proper state owing to bad drainage.

LIMING THE SOIL

Besides digging and trenching the soil, it may, if in a wet condition, also be improved by the addition of lime, which is a most important agent in fertilising the soil. It not only 'sweetens' sour wet land, but makes it drier and more porous, and thus increases its temperature.

It also frequently liberates potash (one of the most important plant foods locked up in the soil), and it is also a great preventive of vermin in the shape of slugs, snails, caterpillars and grubs of all kinds. At the rate of from 10 to 20 cwts. per acre or $\frac{1}{2}$ lb. to 1 lb. per square yard may be applied during the winter months in a powdered state, when the soil is free from vegetation. But while there can be no doubt as to the fertilising properties of lime care must be taken not to be continually dressing the soil with it. It is a bad plan, not only with lime, but with all other fertilisers, to apply one kind only. A change is beneficial, and chemical changes take place between one and the other, but all the changes are more or less useful to the soil. See p. 1030.

Gas Lime also may be applied during the same season, but must be given in smaller quantities, say at the rate of 1 to 2 cwts. per acre, as in a fresh state it is very injurious to plant life. It is, however, a deadly enemy to insect pests. The fresher the gas lime the smaller the proportion of it should be used; about two or three ounces to the square yard would be quite sufficient. The longer it is exposed the less injurious to plant life does it become, as many of its poisonous gases escape into the atmosphere.

HOEING AND RAKING

Next to the spade and the fork the *hoe* is perhaps the most important tool used in garden cultivation. It is made in many forms, shapes and sizes, but that known as the 'Draw Hoe,' which the gardener pulls towards him as he walks forwards, and that known as the 'Dutch Hoe,' which he pushes from him as he walks backwards, are the best known and most used.

Whatever the shape, however, the object in view is the same. The hoe plays many parts in the garden. It is used for drawing drills for seeds, Potatoes or other tubers, for breaking and loosening the soil, for thinning out seedlings, for cutting up weeds, and for keeping the surface of the soil generally clean and in good condition. Like everything else connected with gardening, hoeing requires a good deal of intelligence and knowledge of the crops, otherwise the workman may soon do far more harm than good.

The *rake* also plays an important part in the improvement of the soil. It is indispensable for levelling the ground in the preparation of seed-beds, clearing the weeds and rubbish generally from borders, shrubberies, lawns &c., and its use in the hands of an intelligent workman can never be a drawback in keeping a garden in good order.

MULCHING

The reader will find this expression used many times in connection with the cultural directions given for the various plants described in this work. It is therefore advisable to explain its meaning and value.

A 'mulch' or 'mulching' in gardening language means an extra covering of soil, rotten leaves, or manure, either separately or combined, placed over the roots of plants either after the latter have been newly planted, or at any period during their growth when it may be considered advisable.

The advantages of mulching may be summed up as follows :—

(i.) During the hot and dry summer months it prevents excessive evaporation from the soil and thus not only preserves the moisture for the roots to absorb, but it also prevents the soil from becoming excessively hot by day, and cold by night, thus maintaining a more regular temperature.

(ii.) In winter it protects the roots from frost and also keeps the soil warmer.

(iii.) When a rich mulch is applied to newly planted trees and shrubs, it not only has the above advantages, but the manurial matters contained in it are washed down into the soil and enrich it with food for the benefit of the newly formed or forming roots.

(iv.) A good mulching of rich manure to all kinds of fruit trees after they have set their fruits is highly beneficial in assisting them to swell rapidly and ripen more quickly. Once a plant—no matter whether a tree, shrub, or annual—begins to develop fruit and seeds, a demand is made upon its reserve materials. If these are not quite sufficient to meet the demand, it is easy to conceive that the extra food supplied by means of a good mulching will supply the deficiency.

PLANT FOODS AND MANURES

BESIDES being a rooting medium for plants, the soil may also be regarded as a storehouse containing some of the particular kinds of food required to build up the stems, leaves, flowers, and fruits of plants in conjunction with other foods obtained from the air. A soil is said to be fertile when it contains an abundance of plant food, and sterile or barren when this food is scarce or altogether absent. The great object a gardener has in view therefore is to treat the soil in such a way that it shall always be in a more or less fertile condition, and never be deficient in any of the essential plant foods.

Plants require at least twelve different kinds of food to develop properly, and to bring their flowers or fruits to perfection. These foods are:—

<i>Oxygen</i>	<i>Sulphur</i>	<i>Lime</i>
<i>Carbon</i>	<i>Phosphorus</i>	<i>Soda</i>
<i>Hydrogen</i>	<i>Potash</i>	<i>Magnesia</i>
<i>Nitrogen</i>	<i>Iron</i>	<i>Chlorine</i>

These are present in all cultivated plants in greater or less quantities, besides many other things which are said to be non-essential. As a rule all the foods except Nitrogen, Potash, and Phosphorus are readily obtained from the air, soil, or water by the plants themselves. Lime is often present in sufficient quantities, and is very important for fruit or leguminous crops. Only a small trace of Iron is necessary, yet without its aid the green colouring of leaves cannot be developed. The air supplies Oxygen and Carbon, which are absorbed in a combined state by the leaves of plants and are afterwards split up—the Carbon being retained to build up the frame of the plant, while a large amount of the Oxygen is liberated by the pores of the leaves (see p. 33).

All the mineral substances are provided by the roots, but they must first of all be dissolved by water. Salt (chloride of sodium) is generally found in plants which grow naturally near the sea, and where these have been brought under cultivation, dressings of salt may be given to the soil occasionally, as in the case of Asparagus (p. 1145) and Seakale (p. 1121) &c.

Three important plant foods

The good growth of plants practically depends upon the presence of *Nitrogen*, *Potash*, and *Phosphorus* in such a state that they can readily enter into the plant and assist the other foods in building it up. The absence of any one of these three foods cannot be made good by an extra supply of the others. The gardener need not often worry himself in regard to the nine other foods mentioned above, with the exception of *Lime*; but he should always satisfy himself that his soil is not deficient to any great extent in any of these three foods, the peculiarities and properties of which are referred to below.

Nitrogen.—Although so abundant in the atmosphere—being four-fifths of the whole—this gas is very shy of uniting with others, or of being absorbed by the leaves of plants like carbonic acid gas. There

is an exception in the case of Leguminous plants (see pp. 322–355). It has been found that plants of this order have the peculiarity of developing small nodules on their roots. These nodules are supposed to be the work of bacteria which possess the power of absorbing large quantities of nitrogen from the air, thus bringing it into contact with and fertilising the soil. For this reason it is unnecessary to give Leguminous crops, such as Peas, Beans, Lupins &c., nitrogenous manures. Indeed dressing the soil growing such crops with nitrogenous manures is likely to do a good deal of mischief. The plants get as it were surfeited with a food which they are capable of obtaining easily for themselves. They may require potash and phosphatic manures but never or rarely ever nitrogenous ones. And soil poor in nitrogen may be enriched by the cultivation of Leguminous plants, afterwards digging or ploughing them into the soil.

Uses of Nitrogen.—Nitrogen promotes the growth of plants, giving the leaves a deeper colour and making them larger and more luxuriant. It is chiefly obtained from farmyard manure, and the droppings of various animals—pigs, horses, cows, chickens &c.—but never in a free state. Guano—the excreta of seabirds in South America—nitrate of soda, nitrate of potash and sulphate of ammonia are the principal artificial sources which supply nitrogen. The manures containing it require to be used in very small quantities.

Nitrate of Soda is a mineral salt found in Chili, Peru, and Bolivia, and has of late years become very popular as a quick-acting manure for all kinds of crops. It resembles dirty common salt in appearance, and like that substance readily dissolves in water. Care should therefore be taken when storing it to deposit it in a dry place, otherwise it will lose much of its value.

Care must be exercised in its use for garden crops. If too much is given the leaves of the plants will shrivel up as if they had been boiled. About 1 lb. to forty square yards is usually considered to be a safe dressing, and it may be applied with advantage to such crops as Potatoes, Cabbages and other Cruciferous crops (p. 1113), Beet, Tomatoes &c.

Owing to its fleeting character, and the ease with which it is washed out of the soil, it is obvious that nitrate of soda is only of real value to the roots of any crop of plants in an actively growing state. It should therefore be used to hasten the growth of young plants, or to bring others more quickly into a state of full growth.

As a rule it is best used by itself and not in conjunction with other manures, such as superphosphate which decomposes it. If mixed with farmyard or other organic manures which have the power of extracting

and destroying all its value, it is so much waste, and at the same time there is little use in applying it to any soil which is not actually well supplied with phosphates and potash—the two other important manures referred to above.

Sulphate of Ammonia.—This is very similar in appearance to Nitrate of Soda, but is if anything a little dirtier in colour. It is manufactured from the ammonia liquor of gas works, and is somewhat stronger and more durable in its action than Nitrate of Soda; consequently it need not be used in such large quantities. Although it may be mixed with Superphosphate, Sulphate of Ammonia should never be used in conjunction with lime or chalk, ashes, or a manure known as ‘Thomas’s phosphate’ or ‘basic slag,’ as these drive off the ammonia from it.

Gas Liquor.—This contains a good percentage of ammoniacal manures, and is stronger in action than Sulphate of Ammonia. A gallon of it should be diluted with at least four gallons of water, and may be used as a liquid manure.

Soot.—This is not only a good nitrogenous manure but also contains a certain amount of phosphoric acid and potash, and may therefore be said to be more or less ideal as it contains the three most important plant foods. It is valuable not only for its manurial properties but also for its great value in keeping away slugs, snails, and other vermin.

Other Nitrogenous Manures.—Under this heading may be placed almost all refuse which has been in a living state at one time or another. The refuse from slaughterhouses, such as dried blood, and meat, hoof-parings, old rags, hides, leather &c., are all more or less of manurial value, but they do not yield up their food until in a thoroughly decayed state. They are therefore rather slow-acting in the soil, but are nevertheless valuable for perennial crops.

Phosphatic Manures.—These are derived from phosphates, and have a marked effect in the production and early ripening of fruit, and all garden crops benefit by their presence, as they are compounds of potash, lime, and ammonia—all valuable plant foods. Superphosphate of lime, bones, phosphate of ammonia, and phosphate of potash, are the chief phosphatic plant foods used.

Superphosphate of Lime.—When in a good condition this is a fine greyish powder, dry and friable to the fingers, and not wet and sticky. It has a peculiar smell and tastes very sour or ‘limy.’ About 1 cwt. of it contains 12–14 lbs. of phosphoric acid, or more than is yielded by a ton of good farmyard manure. It should be used carefully, about 1 lb. to every 4 or 5 square yards being sufficient for vegetable and

fruit crops. A smaller quantity, however, is safer for the flower border, applied in spring and lightly forked into the soil as the plants are about to begin growth. The best time as a rule for dressing the soil with superphosphate is in spring when seeds are being sown. If the soil is in a poor condition, superphosphate by itself will not be of much use, and the ground should have had a good dressing of farmyard manure the previous autumn to make it valuable.

Bones.—The value of Bones as a phosphatic manure has long been recognised, and many gardeners are very partial to having a sprinkling of ‘bone-meal’ or ‘bone-flour’ always mixed with soil when repotting or replanting. Bones are, however, a very slow-acting manure, but the process of decomposition and consequent quicker action may be assisted by having them finely crushed. In the form of bone-meal, unadulterated and unsteamed bones contain about 45–50 per cent. of phosphate of lime, and also a small quantity—4–5 per cent.—of ammonia salts. Steamed or boiled bones contain about 60 per cent. of phosphate of lime, but not so much ammonia. The phosphate of lime, however, is not soluble in pure water, but when acted upon by the carbonic acid in ordinary water, rain &c. it gradually dissolves and fertilises the soil.

A manure called *dissolved bones* or *bone superphosphate* is produced by mixing a certain quantity of sulphuric acid (or oil of vitriol) with raw bone-meal—about 9 cwts. of sulphuric acid to 20 cwts. of bone-meal. About one-third of the insoluble phosphate of lime in the bones is changed by the chemical process into a soluble condition, and is thus more readily available for the roots of plants. A reasonable dressing for fruit and vegetable crops is about 1–2 lbs. to every ten square yards, and may be given in winter or spring.

Basic Slag.—This is a dark coloured powdery substance also known as ‘Thomas’s phosphate’ and ‘basic cinder.’ It contains a good deal of oxidised iron (commonly called ‘rust’), but not to any injurious extent. Its chief value lies in the amount of lime it contains in the form of a phosphate, and it is particularly valuable for improving soils which are destitute of lime or chalk, and also vegetable or animal remains called humus. It is best applied in autumn or winter at the rate of 4–8 ounces to the square yard, or 10–20 cwts. to the acre, more or less according to the poverty of the soil in regard to lime and humus. It is good for fruit trees and most garden crops, but will give disappointing results if applied in spring instead of autumn or winter as recommended.

Potash.—While nitrogenous food increases luxurious growth, and phosphatic food large crops of fruit, potash increases the quality and

flavour by manufacturing the sugary ingredients so noticeable in Apples, Pears, Plums, Grapes, Beetroot &c.

Garden soil is rarely lacking in potash, and a supply may always be liberated by the addition of lime. Soil which has been well manured with dung for years is very rich in potash, and in such cases it is scarcely necessary to trouble about obtaining special artificial manures. Where, however, the soil is poor in potash, it will be improved by lime, basic slag, and *kainit*—the latter a cheap and economical manure containing sulphate of potash, common salt, sulphate of magnesia (Epsom Salts) and chloride of magnesia. Besides these, sulphate of potash, muriate of potash, and phosphate of potash all yield potash, as do also the ashes of all vegetables and plants generally. Most fruit and vegetable crops, and particularly those belonging to the Cruciferous group, are improved by the addition or presence of potash manures in the soil.

Other manures.—Besides the above manures, which are all more or less artificially manufactured and brought into a more or less soluble condition so as to be available as plant-food, it is now necessary to refer to others which may be termed natural manures. Of these the best known is certainly :—

Farmyard manure.—This consists of the refuse of litter, solid and liquid excreta of all animals, &c. from stables. To be fit for use in the garden it should be turned over constantly and well watered, to prevent the escape of the volatile ammonia. The water however should not be allowed to drain away and be lost for ever, but means should be taken to secure it and use it as a liquid manure.

Good farmyard manure contains about 10–12 lbs. of *nitrogen*, 10–15 lbs. of *potash*, and 4–9 lbs. of *phosphate*, that is only 24–36 lbs. or less than $\frac{1}{2}$ cwt. altogether of essential plant foods out of a ton of material. The remaining $19\frac{1}{2}$ cwts. of straw or litter however are not absolutely valueless. The material has been alive at one time, and has been produced by the soil and air. When returned to the soil therefore it acts as a kind of tonic to the mineral particles in the soil, it retains moisture in hot weather, and keeps out cold in winter, and has other useful properties that make it on the whole an excellent and popular manure. Some gardeners have an inclination to do without farmyard manure altogether, and rely a good deal upon the chemical or artificial productions referred to above. It is a mistake, however, as mentioned before, to be always dressing soil with the same kinds of manures, and a medium course is best adopted. While farmyard manure may not give such good or clean results as chemical manures for some crops, such as Potatoes for example, that are subject to fungoid

diseases, the use of chemical manures entirely would leave the soil in the course of time impoverished owing to the absence of all humus, and this as already mentioned is a very important ingredient of most soils.

Peat-moss litter, now largely employed for bedding down animals, is also a good manure, but its heating qualities, although rapid, are not so lasting as ordinary stable manure. It however soaks up liquids from the stables much better and holds it in the tissues.

Poultry manure.—Where fowls are kept it is a mistake to waste the cleanings from their pens. A ton of chicken manure yields 18–25 lbs. of *nitrogen*, 12–24 lbs. of *phosphate*, and 6–12 lbs. of *potash*. The excreta should be used with care and should always be well mixed with soil, or made up in bags or sacks and sunk in tanks of water to yield a good liquid manure.

Pigeon manure is even richer in manurial value than that of chickens. A ton contains about 72 lbs. of *nitrogen*, 48 lbs. of *phosphates*, and 25 lbs. of *potash*. It may be used with care in the same way as chicken manure. Indeed the excreta of all animals make excellent manures and are well worth saving for garden purposes. A few experiments in using them will soon enable the gardener to find out the most useful quantities to use.

Guano.—This is the excreta and decayed bodies of the sea-birds that frequent the rocky islands near the coast of Peru. In a saleable state it is a dark brownish or snuff-coloured powder, with a peculiar smell of its own, and weighs about 70 lbs. to the bushel. As a manure its value depends mainly on the amount of ammonia, soluble and insoluble phosphates, and alkaline salts which it contains. One ton of good Peruvian Guano is considered to be equal in manurial value to either 33½ tons of farmyard manure; 20 tons of horse-dung; 38½ tons of cow-dung; 22½ tons of pig-dung; or 14½ tons of 'night soil' or human excrement. Looked at in another way it may be stated that out of 1 cwt. (112 lbs.) of good Guano, there is about 8 lbs. of *nitrogen*, 18 lbs. of *phosphoric acid*, and 3½ lbs. of *potash*—the quantity of each per ton of course being 20 times as much. For garden purposes about 2–4 cwts. per acre, or 1–2 ozs. to the square yard, is a reasonable dressing, but care should be exercised in its use, and it is better to give smaller amounts to most crops until the action has been tested. As a liquid manure it is very valuable, about a tea-spoonful—more or less—to a couple of gallons of water being a good stimulant for flowers. It is better not to wet the foliage of plants with liquid manures of any kind owing to their rather vigorous action.

When buying Guano or any other high class manure it is always

advisable to obtain a warranty as to the amount of available nitrogen, (or ammonia), phosphates, and potash contained in them.

Fish Guano.—This is the dried and powdered refuse from cod and herring and other fish factories, and may be regarded as containing a fair amount of *nitrogen* and *phosphoric acid*. According to the kind of fish used, this guano may contain from 7 to 14 per cent. of nitrogen in the form of ammonia; 13–30 per cent. of phosphate of lime; and only 2–3 per cent. of potash. To be of much value as a fertiliser the oily matters should have been extracted as far as possible, as the presence of oil retards the action of the manure and gives unsatisfactory results. The action of Fish Guano is somewhat similar to that of Peruvian Guano, but it may be used a little more freely, say about 2–10 cwts. per acre, or at the rate of 1–4 ozs. to the square yard.

The above are the principal manures in use, but in various seaside localities seaweed is much valued, chiefly owing to the *potash* salts contained in it. A ton of fresh seaweed contains about 10 lbs. of *nitrogen*, 10 lbs. of *phosphoric acid*, 30–45 lbs. of *potash*, and about 50 lbs. of common salt. It may be turned over several times in a heap and allowed to decompose like ordinary farmyard manure, and in this state may be dug into the soil in the same way.

Old rags, rapecake dust, meat refuse, horn shavings and almost any vegetable remains free from fungus diseases may also be used for manuring the soil.

Coal ashes, which are often recommended in ignorance, should never be applied to any decent soil, as they do more harm than good. If used at all, it should be only to make sticky clayey soil more porous.

PART II

THE HARDY FLOWER GARDEN

THE modern Flower Garden embraces the cultivation of such a variety of plants that it may be as well to enumerate the different groups or sections in which they are usually placed. Thus, many gardens have a place set apart purposely for the cultivation of rock-plants and alpines; also specially prepared borders for choice herbaceous perennials of all sorts; streams, pools, or lakes for water and marsh plants; and also sufficient space for the cultivation of ornamental trees and shrubs.

Although the plants belonging to the various groups are described in their natural orders in the following pages, and may easily be found by referring to the Index, there is a certain convenience in having a list of them all together for ready reference. To facilitate obtaining further information about them, the page at which any particular plant is described is given immediately after the name.

Should the reader, therefore, wish to have a list of the best Annuals, Herbaceous Perennials, Rock Plants, Water Plants, Bulbous Plants, Ornamental and Flowering Trees and Shrubs &c., he has only to consult the lists given below. If he does not know any plant mentioned, he will find a description of it with cultural information at the page quoted after the name.

At the same time should there be a plant in his or her garden the name of which is unknown it will be possible to 'run it down' or determine to which natural order or genus it belongs by means of the 'Key' given at p. 121.

Although the lists are fairly exhaustive the author does not recommend the cultivation of all of them in every garden. This would indeed be impossible in most cases, but a selection should be made according to the taste of the reader, and the known capability of his soil, and what it will grow. As a rule it is more satisfactory to grow a few different kinds of plants well, and study their peculiarities and tastes, their likes and dislikes for certain soils and situations &c., than to fill a garden with many kinds that may be quite unsuitable, or cannot be properly attended to.

ANNUALS AND BIENNIALS

ANNUALS are plants which spring from seed, flower, produce seed, and die in one year or season of growth. Many biennial or even perennial plants are treated as annuals, as it is less trouble to raise them from seeds every year than to house or protect the roots during the winter. 'Hardy' annuals are those plants which may be sown and grown from start to finish in the open air. 'Tender' or 'half hardy' annuals, on the other hand, require to be raised in gentle heat, and must not be planted out until all danger from frost is past; or if sown outside, the operation must be performed later than for hardy annuals.

Hardy annuals may be sown either in pots or pans, or in the places outside in the garden in which they are intended to bloom: whether in rows or patches of course depends on the grower. The soil should be well prepared, raked over, and levelled. The seed should be sown very thinly, and only slightly covered, and gently patted down with a flat board or the back of a spade, and the general instructions given from p. 42 to p. 46 must be borne in mind.

When flowers are required in summer or autumn, hardy annuals may be sown out of doors in March and April. If required in early summer or late spring, then the seeds should be sown early in September. When thinned out, the sturdy seedlings may be afterwards transplanted to their flowering positions, sufficiently early to become established before winter. For further particulars the reader is referred to the article on seeds and seed sowing, pp. 24, 42.

Biennials.—These are plants which usually require two years or seasons of growth to develop fully from seed before they die naturally. The seeds of hardy biennials are usually sown from June to August, and pricked out or transplanted in the autumn to the places in which they are to bloom the following year. Tender biennials must be sown in autumn in a frame or cool house, and the plants must be sheltered in these places until about the end of the following May, when they may be planted out.

The following is a selection of the best annuals and biennials, or plants that may be treated in the same way.

LIST I

A Selection of the most Ornamental Annual and Biennial Plants, or those that may be treated as such

The page at which description and cultural information for each are given appears after the name.

- Abronia umbellata, p. 760.
 Acroclinium roseum, p. 508.
 Adonis autumnalis, p. 145.
 Alyssum maritimum, p. 210.
 Amberboa moschata, p. 551.
 odorata, p. 551.
 Antirrhinum, vars., p. 710.
 Aphanostephus ramosissimus, p. 497.
 Arabis arenosa, p. 206.
 Asperula azurea setosa, p. 487.
 Baeria coronaria, p. 524.
 Balsam, p. 294.
 Brachycome iberidifolia, p. 497.
 Calandrinia discolor, p. 262.
 grandiflora, p. 262.
 Calendula officinalis, p. 544.
 Callistephus hortensis (the type) and various China Asters, p. 499.
 Campanula Loreyi, p. 567.
 macrostyla, p. 566.
 Medium, p. 566.
 sibirica, p. 568.
 spicata, p. 568.
 Candytuft, p. 218.
 Canterbury Bells, p. 566.
 Carnations, Marguerite, p. 241.
 Celosia, p. 762.
 Centaurea cyanus, p. 550.
 moschata, p. 551.
 Centauridium Drummondii, p. 496.
 Centranthus macrosiphon, p. 489.
 Cheiranthus, p. 204.
 China Aster, p. 499.
 Chrysanthemum carinatum, p. 531.
 coronarium, p. 531.
 Clarkia elegans, p. 452.
 pulchella, p. 453.
 Clintonia pulchella, p. 555.
 Cockscomb, p. 762.
 Collinsia bicolor, p. 717.
 Collinsia verna, p. 718.
 Collomia coccinea, p. 663.
 Convolvulus tricolor, p. 686.
 Coreopsis Drummondii, p. 518.
 Cosmidium burridgeanum, p. 522.
 Cosmos bipinnatus, p. 522.
 Datura, p. 692.
 Delphinium, annual vars., p. 158.
 Dianthus sinensis, p. 243.

THE HARDY HERBACEOUS BORDER

IN the flower garden proper, the hardy herbaceous border is undoubtedly the most important feature. Its beauty and variety depend almost entirely on the taste of the owner, and a knowledge of the plants used. Some herbaceous borders nearly always present a bright and attractive appearance owing to a good and tasteful selection of plants arranged with due regard to their various heights, their period of blossoming, and the contrasts produced by the colour of their flowers. Other borders, however, which receive but little or no attention present anything but an attractive appearance.

Many things have to be considered in the making of a good flower border—such as site, aspect, soil, habit, height, colour, and general requirements of each species, and whether they are better grown as individual specimens or in large or small masses or groups to produce the best effect. Indeed it may be said that the chief object in view in making a hardy herbaceous border is to secure a pleasing natural picture with plants and flowers of different habits, heights, colours &c.

The nature of the locality must always be taken into consideration,

and only those plants should be grown that will flourish with ordinary good care and attention. It must be borne in mind that some plants thrive in one locality and make glorious pictures in the flower border, while in other districts—perhaps not many miles distant—they prove to be utter failures, notwithstanding every attention to cultural details.

Unfortunately, this is one of the peculiar things that puzzle gardeners not a little. Many, of an experimental turn of mind, resolve to make a difficult plant grow by hook or by crook if good cultivation can do it. Very often they are highly successful, and very often not. And curiously enough, many of these so-called difficult plants to cultivate, when they fail under what is considered the best treatment, often astonish the disgusted cultivator by growing vigorously and flowering profusely when they have been neglected and left to shift for themselves. A writer in the 'Garden' has illustrated this point very clearly in connection with *Tropæolum speciosum* (see p. 291). He says:—This species was planted in many positions, care being taken to afford a porous root-run and a sufficiency of shade, for in the south it is almost impossible to establish this *Tropæolum* in a situation exposed to the full rays of the sun. After the planting was concluded a certain quantity of roots remained over, and these were placed in holes dug at the foot of a spreading young yew tree, the soil not being disturbed further than was necessary for covering the roots. After this was effected, these latter were not given another thought, as they were not expected to succeed, and had only been roughly planted as an alternative to being thrown away. In course of time all the carefully planted and tended *Tropæolums* disappeared, and for a couple of years the forgotten roots beneath the yew did nothing to advertise their existence. In the third year, however, a vivid splash of vermilion on one of the branches of the yew drew attention to the fact that the plants were not only alive, but in the best of health, in which state they have since remained, garlanding the sombre foliage during the summer months with an opulence of colour that year by year increases in extent.

The moral of this is that the reader must not be discouraged if he should fail to grow a plant under one set of conditions. Should this unfortunately happen, then he should at least try totally different conditions in his garden before finally rejecting the plant as unsuitable.

Site of Herbaceous Borders.—Where a large and varied selection of plants from all quarters of the globe is to be grown in the same border, the best general site is one facing any point of the compass between east and west. There are several choice plants—*Tropæolum speciosum*, mentioned above, for example—that will flourish facing north or east; but the great majority of choice border plants require a position

sheltered from the bleak cold winds of the east and north. This shelter is better and more picturesque if given by means of ornamental trees and shrubs, or thick evergreen hedges. When herbaceous borders are made against walls and outside greenhouses care should be taken not to have the back portion choked up with vegetation with an idea of hiding the wall. The latter object can be secured by training various plants and climbers like Ivies, Vitis, Smilax, Choisya, Clematis, Jasmine, Bignonia &c. over them.

But there is no necessity whatever to have beautiful flower borders near buildings or walls of any sort, or even fringing shrubberies, although all these situations are valuable if properly utilised. The flower border may stand alone in the grass and may be so arranged that sufficient shelter is afforded from a distance by hedges, trees, buildings &c.

Width.—The width of flower borders is often so great that the plants towards the back are so placed as to be too far off to be properly attended to without constantly walking over the border and treading the soil down into a perfectly hard state. Five to six feet wide is quite enough for any border, and it should be so arranged that it may be viewed from both sides. Where flowers are largely cut for room decoration this will be found a convenient width, as it will admit of the flowers being cut from the centre of the bed without trespassing on the soil or the intervening plants.

Where very broad stretches of ground may be used for the flower border, pathways of grass about 2 ft. wide may be left between the borders. This will allow for the erection at intervals of trellises, arches, pergolas &c., over which climbers from each side may be trained up. Where herbaceous borders run parallel with greenhouses or conservatories, as they frequently do, a pathway at the back by the walls will be a great convenience, and will also allow a freer circulation of air among the plants. The taste of the cultivator, however, will always decide where the borders are to be made, how they are to be planted, and the kinds of plants to be used.

Soil.—For general purposes a rich loamy well-drained soil is best. It may be leavened by the addition of manure, leafsoil, peat and sand, as may be required for any particular plant grown in it. It should be from 2 to 3 feet deep and, before planting, well dug or trenched as occasion demands. In the following pages there is frequent reference to 'ordinary good garden soil.' This means any soil which is well-drained and consists of loam, sand, leaf-mould and other vegetable and animal refuse, clay, peat &c., all of which have been thoroughly worked with the addition of manures for years past. It would be difficult without analysis to say of what such a soil was composed.

Planting.—As the herbaceous border is usually intended to last for several years, care should be exercised in selecting and arranging the plants properly at first, to avoid subsequent alterations. If the borders are arranged as recommended it will not be necessary to have all the tall plants at the back, the others sloping downwards to the dwarf ones in front, thus giving a painful air of symmetrical arrangement. Many of the taller kinds may be placed in the centre, and behind or in front of them the dwarfer ones may be planted, according as to whether they require plenty of sunshine or shadow. In fact, the plants should be made to assist each other as much as possible in this respect. A tall plant may be readily used for shading a dwarfer one by its shadow during the hotter and sunnier portion of the day. In the same way a tender plant may be sheltered from the winds if arranged near another of a more hardy constitution.

Massing or Grouping.—It often happens that one plant by itself fails to produce a good effect. It may be straggling in habit and small in flower, and is lost amid more showy surroundings. It is somewhat similar to a solitary soldier in a more or less gay uniform, and a whole battalion dressed in the same way. The individual looks commonplace and excites no comment, but when he is one of a thousand he contributes his share to the brilliant effect of the whole. So it is with many plants. When they are ineffective as single specimens they become handsome and desirable subjects in a flower border when grown together in large masses. If Violets, Primroses, Saxifrages, Asters, Aubrietias, Larkspurs, Anemones, Campanulas, Coreopsis, Gentians, Phloxes, Pentstemons &c. were grown simply as single plants at a great distance from each other, they would never produce the effect, or be so much appreciated as they are when grown in masses and groups.

Colour and Time of Flowering.—This is an important point to consider in arranging the plants. In the following lists some of the best flowers are arranged according to the principal predominating colour, so that the reader will find no difficulty in making a selection for himself. The period of blooming should also be taken into consideration, with a view to obtaining flowers in the open air for as long a period as possible. In this way the flower border will continue to maintain its interest from one year's end to another. As it is often useful to know what plants are likely to bloom in the dullest months of the year, a list of those which blossom between September and May is given at p. 94. It is scarcely necessary to give a detailed list of those which flower from May to September, as during this period there are so many, and there is no difficulty in finding them. In regard to the trees and shrubs, however, a list of which is given at p. 107, some pains have been taken

to give the months in the year at which representatives of most of them are usually in blossom.

General Arrangement of the Flower Border.—This has been treated so well by Miss Jekyll, of Munstead, in a paper read before the Horticultural Society that I take the liberty of reproducing her remarks here :—

‘ An essential feature in a garden of hardy flowers is a well-arranged mixed border. It is here that we can show the true summer flowers at their best, but it is here, more than anywhere else, that the “art of many sacrifices” must be put in practice. For the main spaces plants should be chosen of bold and striking beauty, but as a border of all large plants would have a kind of monotony, certain spaces, chiefly towards the front, but also running back in many parts among groups of taller things, should be planted with those of lower growth. The chief plants for such a border are Oriental Poppies (p. 191), Pæonies (p. 165), the boldest of the Irises (p. 917), Day-Lilies (p. 815), Herbaceous Spiræas (p. 364), *Oenotheras* (p. 453), a few of the best Campanulas (p. 562), Delphiniums (p. 158), Lilies (p. 842), three or four of the best perennial Sunflowers (p. 515), the tall blue Sea-Holly (p. 465), Tritomas (p. 817), Mulleins (p. 701), *Thalictrums* (p. 137), Dahlias (p. 519), Hollyhocks (p. 272), and a few others. These are the plants that will form the great effects of the border. The nearest parts, and some spaces between the taller growths, should have groups of plants of lower stature, and yet of a somewhat bold form of foliage. Of these the broad-leaved Saxifrages (p. 415), and Funkias (p. 816), are among the best. Still dwarfer plants, such as Pinks (p. 238), and Pansies (p. 233), are suitable for the extreme edge.

‘ Each kind of plant in the mixed border should stand in a bold group, and the groups, differing in size and shape, according to the aspect of the plant, should follow one another in a carefully arranged sequence of colour, keeping plants of a colour together, such as Mulleins with *Oenotheras*, and Tritoma with Oriental Poppy. In the case of the last named, it is convenient to actually intergroup the two kinds, for the foliage of the Poppies dies away early and the blank space it would have left becomes covered by the later-growing leaves of the autumn-blooming Tritoma.

‘ Groups of red, orange and strong yellow follow well, and help each other by forming a rich colour harmony. Flowers of a strong blue colour, like Delphiniums, seem to ask for a contrast, such as that of white Lilies (p. 846) or the pale yellow of *Oenothera lamarckiana* (p. 453), and *Verbascum phlomoides* (p. 702), the best of the Mulleins. In practice it is perhaps best to exclude bulbous plants from the mixed

border, "especially in light soils that need frequent enrichment," as the disturbing of the ground, occasioned by division of the plants and manuring, is perilous to the bulbs, the foliage of which has usually disappeared by autumn, and whose places are probably forgotten unless marked by unsightly labels. But exception should be made in favour of the three common Lilies, the White (p. 846), the Orange (p. 848) and the Tiger (p. 857). Labels must be absolutely abolished in the ornamental garden. (See p. 47.)

'Some families of plants, especially those whose beauty is in infinite variety, may best be enjoyed in places almost by themselves, where the eye would be undisturbed by the consideration of other kinds of flowers. A garden of Lilies may be made of great beauty, the groups of Lilies appearing among dwarf and moderate sized shrubs and hardy Ferns. The Pæony family (p. 165) is another example of a large range of summer flowers that deserve such treatment in addition to their use in other places. A whole wealth of garden beauty exists in this one tribe alone, for, apart from those best known—namely, the double varieties of the old garden kind, the Chinese herbaceous (p. 168) and the old Tree Pæony (p. 171)—there are many other kinds, both species and their cultivated varieties, that are happily available for garden use.

'Many a beautiful garden picture may also be made by the placing of quite a small number, or even a single example of some stately plant in a quiet place by itself, such as a group of *Lilium giganteum* (p. 849) with its noble flower spikes and its broad glistening leaves. A group of this grand Lily, in partial shade and backed by trees or small shrubs, shows one of the stateliest forms that can be seen of a flowering plant of one year's growth.

'Such another example is offered by the Californian Tree Poppy (*Romneya Coulteri*, p. 190) which, when well established, will grow in one season into a bush 7 feet high and as much through. It is a remarkably beautiful plant and to an eye trained to harmonies of colour singularly pleasing in the relation of its large milk-white flowers and pale blue-green leaves. It delights in a sunny well-sheltered place in a light soil.

'Old walls are easily made beautiful by sowing a few seeds of Wall-flowers (p. 240), Snapdragon (p. 710), Red Valerian (p. 490), and Rock Pinks (p. 245), and even a heap of hungry sand will grow to perfection the handsome Lyme Grass (p. 959) and the beautiful Sea-Holly (p. 465).

'There is no end to the interest of this kind of gardening, and the harder the problem the greater the triumph when, for instance, a difficult or ugly piece of ground has been *compelled* into beauty, and what was before unsightly is made delightful to the eye, and with such

skill that the result looks, not as if it had been *done*, but as if it had *happened*.

'It should be remembered that a beautiful garden is a place of pleasant labour and happy restfulness, and that the more it can be filled with perfect pictures, the more it gives delight to the eye and solace to the mind, and the nearer it approaches to the making of an earthly paradise.'

The following is a list of the best Herbaceous Perennial Plants for cultivation in the flower border. After each name the page at which information in regard to description, culture &c. is given is indicated in figures.

LIST III

A Selection of Herbaceous Plants etc. that will grow in more or less Shady Places. The description, culture, and propagation will be found at the page mentioned after the names.

- Acanthus, vars., p. 736.
- Achillea Ptarmica fl. pl., p. 529.
- Aconitum, vars., p. 162.
- Actæa, vars., p. 164.
- Ajuga reptans, p. 759.
- Anemone, vars., p. 139.
- Aquilegia vulgaris, p. 158.
- Aralia edulis, p. 470.
 nudicaulis, p. 470.
 racemosa, p. 470.
- Aristolochia, vars., p. 773.
- Artemisia, vars., p. 538.
- Arum Draunculus, p. 954.
 italicum, p. 955.
- Arundinaria, vars., p. 965.
- Asclepias, vars., p. 647.
- Asperula odorata, p. 487.
- Asphodelus ramosus, p. 822.
- Aster, vars., p. 500.
- Astilbe, vars., p. 414.
- Astrantia, vars., p. 466.
- Baneberry, p. 164.
- Baptisia, vars., p. 323.
- Betonica grandiflora, p. 755.
- Borago orientalis, p. 674.
- Bromus, vars., p. 959.
- Bupthalmum grandiflorum, p. 511.
 salicifolium, p. 511.
- Calystegia vars., p. 684.
- Campanula, vars., p. 563.
- Centaurea montana, p. 551.
- Chelidonium majus, p. 196.
- Clematis, vars., p. 131.
- Convallaria majalis, p. 813.
- Coreopsis lanceolata, p. 518.
- Cortusa Matthioli, p. 624.
- Corydalis nobilis, p. 200.
- Crambe cordifolia, p. 221.
- Cyclamen, vars., p. 626.
- Cynoglossum Omphalodes, p. 672.
- Cypripedium, vars, p. 892.
- Delphinium, vars., p. 158.
- Dicentra spectabilis, p. 199.
- Digitalis, vars., p. 722.
- Dodecatheon, vars., p. 626.
- Doronicum Pardalianches, p. 540.
 plantagineum, p. 540.
- Dracocephalum Ruyschia-num, p. 752.
- Echinops, vars., p. 547.
- Elymus arenarius, p. 959.
- Epigæa repens, p. 578.
- Epilobium angustifolium, p. 452.
- Epimedium, vars., p. 184.
- Equisetum sylvaticum, p. 1024.
 Telmateia, p. 1023.
- Eranthis hyemalis, p. 154.
- Eryngium alpinum, p. 465.
- Erythronium, vars., p. 869.
- Eupatorium, vars., p. 494.
- Ferula, vars., p. 468.

- Fragaria*, vars., p. 376.
Fritillaria, vars., p. 857.
Funkia, vars., p. 816.
Galanthus nivalis, p. 906.
 plicatus, p. 906.
Gaultheria, vars., p. 575.
Gentiana septemfida, p. 656.
Geranium, vars., p. 285.
Geum, vars., p. 374.
Gillenia trifoliata, p. 369.
Hedysarum, vars., p. 345.
Helianthus, vars., p. 515.
Helleborus, vars., p. 152.
Helonias bullata, p. 878.
Hemerocallis, vars., p. 815.
Heuchera, vars., p. 427.
Hieracium aurantiacum,
 p. 553.
Hop, p. 788.
Humulus Lupulus, p. 788.
Hypericum, vars., p. 265.
Inula Helenium, p. 510.
Iris, vars., p. 917.
Lamium, vars., p. 756.
Lathyrus, vars., p. 348.
Lavatera, vars., p. 274.
Leucojum, vars., p. 907.
Liatris spicata, p. 495.
Lilium, vars., p. 842.
Linnæa borealis, p. 482.
Lupinus polyphyllus, p. 326.
Lychnis diurna, p. 256.
 vespertina, p. 257.
Lysimachia, vars., p. 629.
Lythrum, vars., p. 451.
Malva, vars., p. 275.
Meconopsis nepalensis,
 p. 194.
 Wallichii, p. 194.
Medicago, vars., p. 333.
Melittis Melissophyllum,
 p. 754.
Mertensia, vars., p. 676.
Mimulus moschatus, p. 720.
Mitchella repens, p. 488.
Monarda, vars., p. 750.

Onopordon Acanthium,
 p. 548.
Ornithogalum, vars., p. 842.
Pæonia, vars., p. 165.
Panicum altissimum, p. 962.
 capillare, p. 962.
 virgatum, p. 962.
Phlomis, vars., p. 757.
Physostegia, vars., p. 754.
Podophyllum, vars., p. 185.
Polemonium reptans, p. 666.
Polygonatum multiflorum,
 p. 811.
Polygonum affine, p. 768.
 cuspidatum,
 p. 769.
Primula, vars., p. 604.
Pyrola, vars., p. 598.
Ranunculus aconitifolius, fl.
 pl., p. 146.
Rubus, vars., p. 371.
Rudbeckia californica,
 p. 514.
 hirta, p. 514.
 laciniata, p. 514.
 triloba, p. 515.
Ruscus aculeatus, p. 810.
 racemosus, p. 810.
Sanguinaria canadensis,
 p. 195.
Saponaria officinalis, p. 249.
Saxifraga cordifolia, p. 419.
 crassifolia, p. 419.
 Fortunei, p. 421.
 Geum, p. 421.
 umbrosa, p. 426.
Scilla, vars., p. 838.
Sedum spectabile, p. 441.
Smilacina bifolia, p. 813.
 stellata, p. 813.
Spigelia marilandica, p. 649.
Spiræa, vars., p. 364.
Symphytum, vars., p. 673.
Thalictrum, vars., p. 137.
Tradescantia virginica,
 p. 807.
Trillium grandiflorum, vars.,
 p. 880.
Trollius, vars., p. 151.
Tulipa, vars., p. 860.
Tussilago fragrans, p. 539.
Uvularia grandiflora, p. 879.
Valeriana, p. 488.
 officinalis, p. 489.
 Phu, p. 489.
Veratrum album, p. 881.
 nigrum, p. 881.
Vernonia, vars., p. 493.
Vinca, vars., p. 645.
Viola, vars., p. 228.
Xerophyllum asphodelioides,
 p. 878.

LIST IV

Trailing and Climbing Plants, for covering Bowers, Trellises, Railings, Old Trees, Stumps, Rockwork, Banks, Walls &c.

- Abobra viridiflora*, p. 462.
Actinidia polygama, p. 267.
Adlumia cirrhosa, p. 199.
Akebia quinata, p. 179.
Apios tuberosa, p. 351.
Aristolochia Siphon, p. 773.
 tomentosa,
 p. 773.
Bignonia capreolata, p. 731.
Bryonia dioica, p. 461.
Calystegia dahurica, p. 684.
 pubescens, p. 684.
Cissus davidiana, p. 309.
 japonica, p. 309.
 platanifolia, p. 309.
 viticifolia, p. 310.
Clematis, vars., p. 131.
Convolvulus arvensis,
 p. 685.
 mauritanicus,
 p. 685.
Eccremocarpus scaber,
 p. 734.
Grammatocarpus volubilis,
 p. 459.
Hablitzia tamnoides, p. 765.
Hedera, vars., p. 471.
Holboëllia latifolia, p. 179.
Humulus Lupulus, p. 788.
Ipomœa, vars., p. 683.
Jasminum nudiflorum,
 p. 636.
 officinale, p. 637.
 revolutum, p. 637.
Lapageria, vars., p. 810.
Lardizabala biternata,
 p. 179.
Lathyrus, vars. (Sweet Peas),
 p. 348.
Lonicera Caprifolium,
 p. 483.
 confusa, p. 483.
 flava, p. 483.
 japonica, p. 484.
 Periclymenum,
 p. 484.
Lycium europæum, p. 692.
Menispermum canadense,
 p. 178.
Mina lobata, p. 684.
Mutisia decurrens, p. 551.

Passiflora cœrulea, p. 460.
Periploca græca, p. 647.
Polygonum baldschuanicum,
 p. 768.
dumetorum,
 p. 769.

Smilax, vars., p. 808.
Solanum jasminoides, p. 689.
Stachyurus præcox, p. 268.
Tamus communis, p. 884.
Tecoma radicans, p. 732.
Thunbergia alata, p. 735.

Tropæolum, vars., p. 290.
Virginian Creeper, p. 309.
Vitis, vars., p. 307.
Wistaria sinensis, p. 338.

LIST V

A Selection of Hardy Plants with White Flowers

Achillea Clavennæ, p. 528.
Ptarmica pl.,
 p. 529.
serrata pl., p. 529.
umbellata, p. 529.
Aconitum Napellus albus,
 p. 163.
Actæa spicata, p. 164.
Allium neapolitanum,
 p. 831.
Alyssum maritimum, p. 210.
Ammobium alatum, p. 509.
Androsace Chamæjasme,
 p. 622.
Anemone alba, p. 139.
alpina, p. 140.
japonica alba,
 p. 142.
narcissiflora,
 p. 142.
nemorosa, p. 142.
sylvestris, p. 144.
thalictroides,
 p. 138.
trifolia, p. 144.
vitifolia, p. 144.
Antennaria dioica, p. 507.
Anthemis Biebersteini,
 p. 530.
Antirrhinum majus albus,
 p. 710.
Aquilegia vulgaris alba,
 p. 158.
Arabis, vars., p. 205.
Arenaria montana, p. 260.
verna, p. 260.
Argemone grandiflora,
 p. 193.
Asperula odorata, p. 487.
Asphodelus ramosus, p. 823.
Astilbe japonica, p. 414.
rivularis, p. 414.
Astragalus hypoglottis albus,
 p. 343.
Bellium, vars., p. 498.
Calla æthiopica, p. 955.
palustris, p. 955.
Callistephus hortensis, vars.,
 p. 499.
Campanula cæspitosa alba,
 p. 563.

Campanula carpatica alba,
 p. 563.
glomerata alba,
 p. 564.
lactiflora,
 p. 565.
lamiifolia,
 p. 565.
latifolia alba,
 p. 565.
Medium alba,
 p. 566.
nitida, p. 566.
persicæfolia
alba, p. 566.
pyramidalis
alba, p. 567.
rotundifolia
alba, p. 568.
speciosa,
 p. 568.
Trachelium
alba, p. 568.
Cardamine trifolia, p. 207.
Centranthus ruber albus,
 p. 489.
Cerastium, vars., p. 258.
Chrysanthemum Leucanthemum,
sinense, numerous
 white-flowered vars.,
 p. 531.
Clematis Flammula, p. 133.
montana, p. 134.
recta, p. 135.
Convallaria majalis, p. 813.
Crambe cordifolia, p. 221.
pinnatifida, p. 222.
Crocus, white vars., p. 936.
Cynoglossum linifolium,
 p. 671.
Dahlia, white vars., p. 519.
Dianthus Caryophyllus, white
 vars., p. 240.
deltoides albus,
 p. 244.
plumarius albus,
 p. 246.
Dictamnus Fraxinella alba,
 p. 296.
Digitalis, vars., p. 722.
Dryas octopetala, p. 374.

Epilobium angustifolium
album, p. 452.
Erinus alpinus albus, p. 723.
Erythronium Dens-canis
album, p. 870.
giganteum,
 p. 870.
grandiflorum,
 p. 871.
Hartwegi,
 p. 871.
Eupatorium ageratoides,
 p. 494.
aromaticum,
 p. 494.
Fritillaria Meleagris alba,
 p. 859.
Funkia grandiflora, p. 817.
Galanthus, vars., p. 906.
Galega officinalis alba,
 p. 337.
Gentiana asclepiadea alba,
 p. 653.
Geranium pratense albus,
 p. 286.
sylvaticum albus,
 p. 287.
Gladiolus Colvillei albus,
 p. 950.
Gypsophila elegans, p. 248.
paniculata,
 p. 249.
Helleborus niger, p. 153.
Hepatica triloba alba, p. 141.
Hesperis matronalis alba
plena, p. 213.
Hoteia japonica, p. 414.
Hutchinsia alpina, p. 220.
Hyacinthus, vars., p. 833.
Iberis corifolia, p. 218.
corræefolia, p. 218.
saxatilis, p. 219.
semperflorens, p. 219.
Iris florentina, p. 922.
germanica alba, p. 923.
pumila albida, p. 929.
Isopyrum thalictroides,
 p. 154.
Jeffersonia diphylla, p. 184.
Lamium maculatum albus,
 p. 756.

- Lathyrus latifolius albus, p. 348.
 Leucanthemum lacustre, p. 534.
 Leucojum aestivum, p. 907.
 vernum, p. 907.
 Libertia formosa, p. 942.
 Lilium Browni, p. 845.
 candidum, p. 846.
 japonicum, p. 850.
 longiflorum, p. 851.
 speciosum album, p. 855.
 washingtonianum, p. 857.
 Linum monogynum, p. 284.
 perenne album, p. 284.
 Lupinus polyphyllus albus, p. 326.
 Lychnis vespertina fl. pl., p. 257.
 Malva moschata alba, p. 275.
 Michauxia campanuloides, p. 560.
 Muscari botryoides alba, p. 832.
 Myosotis sylvatica alba, p. 678.
 Narcissus poeticus, p. 903.
 Nicotiana affinis, p. 695.
 Nierembergia rivularis, p. 698.
 Nymphæa alba, p. 186.
 Nymphæa hybrids, p. 187.
 Oenothera eximia, p. 454.
 speciosa, p. 454.
 taraxacifolia, p. 455.
 Onosma albo-roseum, p. 681.
 Ornithogalum arabicum, p. 842.
 pyramidale, p. 842.
 Ornithogalum umbellatum, p. 842.
 Oxalis Acetosella, p. 293.
 Pæonia, vars., p. 165.
 Pansy, vars., p. 233.
 Paradisia Liliastrum, p. 823.
 Phlox, numerous white hybrids, p. 662.
 subulata alba, p. 662.
 Platycodon grandiflorum album, p. 559.
 Polianthes tuberosa, p. 915.
 Potentilla alba, p. 377.
 Primula involucrata, p. 610.
 Munroi, p. 610.
 nivalis, p. 612.
 pubescens alba, p. 614.
 Prunella grandiflora alba, p. 754.
 Pyrethrum Parthenium fl. pl., p. 536.
 roseum album, p. 537.
 serotinum, p. 535.
 Ranunculus aconitifolius plenus, p. 146.
 alpestris, p. 146.
 amplexicaulis, p. 146.
 Romneya Coulteri, p. 190.
 Sagittaria sagittifolia plena, p. 806.

 Zinnia, vars., p. 512.

LIST IX

Plants that flower between September and May. The Dates are approximate only. For Trees and Shrubs see p. 107.

September and October

- Abronia umbellata, p. 760.
 Aconitum japonicum, p. 163.
 Alyssum maritimum, p. 210.
 Amaryllis Belladonna, p. 912.
 Ammobium alatum, p. 509.
 Anemone japonica, p. 142.
 Aster, vars., p. 501.
 Bulboecidium autumnale,
 p. 877.
 Calandrinia Menziesii, p. 262.
 umbellata, p. 262.
 Callistephus hortensis,
 p. 499.
 Chrysanthemum, vars.,
 p. 531.
 Colchicum autumnale,
 p. 876.
 speciosum,
 p. 876.
 variegatum,
 p. 876.
 Coreopsis, vars., p. 518.
 Cosmos bipinnatus, p. 522.
 Dahlia, vars., p. 519.
 Erianthus Ravenneæ, p. 960.
 Erigeron aurantiacus, p. 506.
 Gaillardia, vars., p. 527.
 Gazania, vars., p. 546.
 Gladiolus, vars., p. 947.
 Glycerium argenteum, p. 960.
 Gypsophila elegans, p. 248.
 Heuchera sanguinea, p. 427.
 Lobelia fulgens, p. 557.
 Lychnis haageana, p. 257.
 Montbretia crocosmiæflora,
 p. 946.
 Œnothera, vars., p. 453.

Pentstemon, vars., p. 712.
 Phlox, vars., p. 658.
 Phygellus capensis, p. 711.
 Pyrethrum Parthenium fl. p.
 p. 536.
 vars., p. 536.
 Rudbeckia, vars., p. 514.
 Saponaria calabrica, p. 250.
 Sternbergia, vars., p. 908.
 Tagetes, vars., p. 525.
 Tritoma, vars., p. 817.
 Venidium calendulaceum,
 p. 545.
 Verbena, vars., p. 740.
 Zauschneria californica,
 p. 452.
 Zinnia, vars., p. 512.

November to January

Colchicum autumnale, p. 876.
 Cyclamen, vars., p. 626.
 Galanthus nivalis, p. 906.

Helleborus niger, p. 153.
 Iris stylosa, p. 933.
 Petasites fragrans, p. 539.
 Viola, p. 228.

February and March

Anemone angulosa, p. 140.
 apennina, p. 140.
 Hepatica, p. 142.
 Aubrietia deltoidea, p. 209.
 Bulbocodium vernum, p. 877.
 Cheiranthus, p. 204.
 Chionodoxa Luciliæ, p. 837.
 Eranthis hyemalis, p. 154.
 Erica mediterranea, p. 581.
 Galanthus, p. 906.
 Helleborus, p. 152.
 Iris persica, p. 928.
 Leucojum vernum, p. 908.
 Narcissus, vars., p. 893.
 Scilla sibirica, p. 840.
 Viola, p. 228.

April

Adonis vernalis, p. 144.
 Æthionema grandiflorum,
 p. 217.
 Anemone fulgens, p. 141.
 Aquilegia cærulea, p. 156.
 Auricula, p. 618.
 Caltha palustris, p. 150.
 Centaurea montana, p. 250.
 Convallaria majalis, p. 813.
 Dielytra spectabilis, p. 199.
 Doronicum, vars., p. 540.
 Fritillaria imperialis, p. 858.
 Gentiana, vars., p. 652.
 Hoteia japonica, p. 414.
 Kaulfussia amelloides,
 p. 498.
 Pæonia, vars., p. 165.
 Primroses, p. 604.
 Reineckia carnea, p. 814.
 Tulips, p. 860.

LIST X

A Selection of the finest Hardy Bulbous and Rhizomatous Plants for the Outdoor Garden. Most of these belong to the Orders Amaryllideæ (p. 893), Liliaceæ (p. 808), and Irideæ (p. 916), but a few to other Orders.

Acis autumnalis, p. 908.
 Agapanthus umbellatus,
 p. 826.
 Allium, vars., p. 830.
 Alstroemeria, vars., p. 914.
 Amaryllis Belladonna, p. 912.
 Anomathæca cruenta, p. 944.
 Anthericum, p. 825.
 Antholyza, vars., p. 914.
 Arum crinitum, p. 953.
 Dracunculus, p. 954.
 italicum, p. 954.
 Asphodelus, vars., p. 822.
 Brodiaea coccinea, p. 827.
 congesta, p. 828.
 grandiflora, p. 828.
 Bulbocodium vernum,
 p. 877.
 Calla palustris, p. 955.
 Calliprora lutea, p. 829.
 Calochortus, vars., p. 872.
 Calopogon, p. 891.
 Calypso borealis, p. 890.
 Camassia, p. 841.
 Chionodoxa, p. 891.
 Colchicum, vars., p. 875.
 Crinum, p. 911.
 Crocosma aurea, p. 945.
 Crocus, vars., p. 936.

Cypripedium acaule, p. 892.
 Calceolus,
 p. 892.
 guttatum,
 p. 892.
 spectabile,
 p. 893.
 Eremurus, vars., p. 824.
 Erythronium, vars., p. 869.
 Fritillaria, vars., p. 857.
 Funkia, vars., p. 816.
 Galanthus, vars., p. 906.
 Galtonia, vars., p. 831.
 Gladiolus, vars., p. 947.
 Hemerocallis, vars., p. 815.
 Hippeastrum, p. 910.
 Hyacinthus, vars., p. 833.
 Iris, vars., p. 917.
 Ixiolirion, p. 913.
 Kniphofia, vars., p. 817.
 Leucojum æstivum, p. 908.
 vernum, p. 908.
 Lilium, vars., p. 842.
 Lycoris, p. 912.
 Merendera Bulbocodium,
 p. 877.
 Montbretia crocosmiæflora,
 p. 946.
 Muscari, vars., p. 832.

Narcissus, vars., p. 893.
 Ophrys, vars., p. 892.
 Orchis, vars., p. 891.
 Ornithogalum, vars., p. 842.
 Polianthes tuberosa, p. 915.
 Polygonatum, vars., p. 811.
 Puschkinia scilloides, p. 837.
 Richardia africana, p. 955.
 Schizostylis coccinea, p. 943.
 Scilla, vars., p. 838.
 Sisyrinchium, vars., p. 943.
 Sparaxis pulcherrima, p. 943.
 Sprekelia, p. 910.
 Sternbergia lutea, p. 909.
 Tigridia Pavonia, p. 936.
 Tricyrtis hirta, p. 879.
 Trillium grandiflorum,
 p. 880.
 Tritoleia uniflora, p. 830.
 Tritoma, vars., p. 817.
 Tritonia, p. 946.
 Tulipa, vars., p. 860.
 Watsonia, vars., p. 945.
 Xerophyllum, p. 878.
 Zephyranthes Atamasco,
 p. 909.
 candida,
 p. 910.

THE ROCK GARDEN

THIS is one of the most important and picturesque features in the modern flower garden. Although many of the plants recommended for the Rock Garden will grow perfectly well in the flat flower border, still they appear in a different light and often to better advantage when cultivated among the plants usually associated with alpine heights.

The rockery is an attempt to imitate nature on a small scale by arranging masses or boulders of rock and earth more or less artistically and growing upon them, or between the chinks, plants usually found at high elevations on the mountains of Europe and other parts of the globe. It is only within the last twenty-five or thirty years that the formation of beautiful rockeries has been seriously taken in hand. Before that time all kinds of material did duty for a rockery, but usually not the slightest attempt at copying nature or studying the interests of the plants was made. And it was not until Mr. Robinson, in his valuable little book dealing with 'Alpine Plants,' opened the eyes of the public to a better and more rational method of building rockeries and growing alpine plants upon them, that anything like a good rock garden was to be found in the kingdom. Now there are many good and several bad ones, but as the light is spreading we may hope to see the latter dwindling in number every year.

Formation of a Rock Garden.—The Rev. C. Wolley-Dod, of Edge Hall, Malpas, Cheshire, who has for very many years been an expert cultivator of all kinds of hardy herbaceous and alpine plants, writing about the formation of a rockery a few years ago in the Royal Horticultural Society's 'Journal,' made the following observations, which deserve every attention :—

'The forms in which the rockery, usually so called, can be constructed may be divided into three: (1) the "barrow-shaped" rockery, (2) the "facing rockery," and (3) the "sunk rockery." The first may be raised anywhere, the other two depend partly upon the configuration of the ground. No wood or tree roots should be used to supplement any of them; they must be all stone. The kind of stone is seldom a matter of choice; everyone will use what is most handy. The rougher and more unshapely the blocks the better. The size should vary from 40 to 50 lbs. to 3 or 4 cwt. No mortar or cement for fixing them together must ever be employed; they must be firmly wedged and

interlocked, and depend upon one another, and not upon the soil between them, to keep them in their places. This rule is of the utmost importance; if it is neglected, a long frost or an excessive rainfall may cause the whole structure to collapse. Each successive part of the stone skeleton must be put together before the soil is added. This applies to all rockeries.

‘**Size, Aspect, &c.**—The most convenient size for the barrow-shaped rockery is about 4 ft. high, and 6 or 7 ft. through at the base. The length is immaterial. If the long sides face north-east and south-west it will afford perhaps the best variety of aspect; but the amount of sunshine each plant gets will depend on the arrangement of each stone as much as upon the main structure.

‘There cannot be too many projections, and care must be taken to leave no channels between the stones by which the soil can be washed down to the base. Overhanging brows beneath which plants can be inserted are very useful; large surfaces of stone may here and there be left exposed, and irregularity of form is far better than symmetry. A formal arrangement of flat pockets or nests offends the eye without helping the cultivator, as the tastes of alpine plants as regards slope of surface and moisture at their roots are very various.

‘As for the degree of slope from base to the summit of the barrow, it will not be uniform. In some places there will be an irregular square yard of level on the top, bounded by large cross key-stones, for which the largest stones should be reserved. In other parts the sides will slope evenly to the ridge; or the upper half may be perpendicular, leaving only wide crevices to suit the taste of certain plants.

‘If the blocks are very irregular in form, and their points of contact as few as possible, providing only for secure interlocking, there will be plenty of room for soil to nourish the plants. Ever-changing variety of stone surface, both above and below the soil, is the object to be aimed at, and any sort of symmetry must be avoided.

‘**The “Facing Rockery.”**—The second form, or “facing rockery,” is dependent upon the natural shape of the ground surface. Wherever there is a steep bank facing south or east, it may be utilised for the growth of alpine plants. The stones, as before advised, should be large and unshapely, and be buried to two thirds of their bulk, and form a very uneven surface, all being interlocked from top to bottom as described.

‘Rockeries of this form are less liable to suffer from drought; if the surface covered is large, access to all parts should be provided by convenient stepping stones, because, although every stone in the structure ought to be capable of bearing the weight of a heavy man without

danger of displacement, it is better not to have to tread upon the plants.

‘**The “Sunk Rockery.”**—This is perhaps the best of all, but entails rather more labour in construction. Where subsoil drainage is perfect, a sunk walk may be made, not less than 10 to 12 feet wide, with sloping sides. The sides may be faced with stones, as described in the “faced rockery,” and all or part of the excavated soil may be made into a raised mound, continuing the slopes of the excavated banks, above the ground level, and thus combining the facing rockery and the barrow rockery.

‘If the outer line of this portion above the ground be varied by small bays, every possible aspect and slope may be provided to suit the taste of every plant. However, unless drainage is perfect, a sunk walk, rising to the ground-level at each end, would not be feasible. But a broad walk, excavated into the side of a hill and sloping all one way, could be adapted to a structure nearly similar to that described; or the ground may be dug out in the form of an amphitheatre to suit the taste or circumstances.

‘But whatever the form of the rockery adopted, let the situation be away from the influence of trees, beyond suspicion of the reach of their roots below, or their drip, or even their shade, above. Trees which shelter from only high winds are so far serviceable, and so are walls and high banks. There are few alpine plants for which a storm-swept surface is good, but trees are objectionable where they lessen the light, which is an important element in the welfare of most mountain plants. The shade and shelter afforded by the stones and form of the structure itself is the best kind of shade and shelter.

‘**Soil for Alpine and Rock Plants.**—We now come to the subject of soil, which is very important, though I attach less importance to it than others do who have written on the subject. I hold that where atmospheric and mechanical conditions are favourable, the chemical combination of the soil is of secondary consideration.

‘It is true that in nature we find that the flora of a limestone mountain differs in many particulars from that of a granite mountain, and on the same mountain some plants will thrive in heavy retentive soil, while others will be found exclusively in peat or sand. But for one who is beginning to cultivate alpine plants to have to divide them into lime-lovers and lime-haters, lovers of sand and lovers of stiff soil, is an unnecessary aggravation of difficulties.

‘So large a proportion of ornamental plants are contented with the soil which most cultivators provide for all alike—even though in nature they seem to have predilections—that where an amateur has only one rockery it would be too perplexing to study the partiality of every plant,

and to remember every spot where lime-lovers or their opposites had been growing. While saying this, I confess that I have some rockeries where both soil and rock are adapted exclusively for lime plants ; others from which lime is kept away, and where both soil and rock are granitic ; but the great majority of plants thrive equally well on both. . . .

‘ With regard to soil, then, we must take care that it does not retain stagnant moisture and yet it must not dry up too readily. Plants must be able to penetrate it easily with their roots, the lengths of some of which must be seen to be believed. Good loam, with a little humus in the form of leaf-mould or peat, and half or three-quarters of the bulk composed of stone riddlings from the nearest stone quarry, and varying in size from that of rape seed to that of horse beans, make up a soil with which most alpine plants are quite contented. . . .

‘ Where you are convinced that lime is useful, it may be added as pure lime, not planting in it till thoroughly slaked by mixture with the soil. Rough surface dressing is a thing in which all alpine plants delight, as it keeps the top of the soil sweet and moist and prevents their leaves being fouled. Use for this purpose riddled stone, which is better than gravel, as round pebbles are easily washed off the slope by rain or in watering.

‘ **Raising Alpine Plants from Seed.**—A few words may be in place here about raising alpine plants from seed ; for constant succession is necessary, the duration of their life in cultivation being, for many obvious reasons, far shorter than in their native home. Reproduction from seed, where seed can be obtained, ensures the healthiest and finest growth ; and there is no better way of getting seed than saving it yourself.

‘ In several cases the first hint I have had that a plant has ripened fertile seed has been the recognition of a seedling near the parent ; and this experience has taught me always to look carefully for seed after the flowering of rare specimens.

‘ I need not say, therefore, that I disapprove of the practice of cutting off flower-heads as soon as they wither ; in some cases the seed-head is nearly as ornamental as the flower ; but I have before said that discretion must be used even in this, as seedlings of some things are troublesome from their number.

‘ When ripe seed is gathered I recommend its being sown at once. It is then more likely to come up quickly ; and as all such plants as we grow on rockeries are better sown in pans, there is seldom difficulty in keeping small seedlings through the winter. The greatest enemy we have in the process is the growth of Lichen, the worst being the *Marchantia* or Liverwort, which completely chokes tender growth.

A coating of finely sifted burnt earth on the surface, and a piece of glass laid over the pan, especially if no water is used for them unless it has been boiled, reduces this trouble to a minimum. But sowings of choice and rare seed should be carefully watched, and the Liverwort picked off at the first appearance.

‘**Division and Cutting.**—Many alpine seem never to ripen seed in cultivation, and must be reproduced by division or cuttings. The skill required to do this varies greatly with different subjects: where a shoot can seldom be found more than half an inch long, as in the case of two or three hybrid alpine Pinks, the “striking” needs delicate manipulation. Other things grow very slowly, though not long-lived, and a constant succession from cuttings must be ensured. Some of the terrestrial Orchids—such as Bee, Fly, and Spider, excellent subjects for rockery—we must be contented to keep as long as they choose to live, as they never seem to increase in cultivation at all, though they may flower well year after year.

‘But there are not a few plants which refuse to be tamed, and from the time they are planted in our gardens seem always to go from bad to worse, and are never presentable in appearance for two seasons together. Of these I may instance *Gentiana bavarica* (p. 653) and *Eritrichium nanum* (p. 673), which I believe no skill has ever kept in cultivation without constant renewal, and which perhaps are never likely to repay the trouble of trying to keep them alive on an English rockery. In all alpine gardening there will be (even where equal skill is exerted) different degrees of success according to the surrounding conditions, and it must not be expected that the same soil and treatment which keeps a hundred rare alpine in perfect health at Edinburgh will be equally fortunate at Kew.

‘**Cold Frames.**—Where the area of rockery is considerable a cold frame (see p. 47) should be assigned for keeping up the supply of plants for it—cuttings and seedlings—in pots. The best treatment of these plants in winter has been much discussed in gardening journals. I may say that I think all attempts to imitate natural conditions, such as snow and long rest, by unnatural means are mistakes. During warm winters, mountain plants will grow and must be allowed to grow, and to keep them unnaturally dark or drying when growing is fatal to their health. Even in severe frosts air must be given abundantly in the daytime and the frames must not be muffled up. Stagnant air, whether damp or dry, is their worst enemy; but if the weather is warm enough to set them growing, they may easily die for want of moisture. I will not say more than this, for experience is the best guide, and every one thinks he can manage his frames better

than his neighbour; but of the use of frames for flowering alpiners in pots I must add a few words.

‘There are certain very early flowering alpiners upon which a mixture of admiration and lamentation is bestowed at the end of every winter. Their flowers are often beautiful in a treacherous fortnight at the beginning of February, and are suddenly destroyed by a return of winter in its severest form. I may mention, among others, *Saxifraga burseriana* and *sancta*, and their near relatives and hybrids, *Primula marginata* and *intermedia*, *Androsace carnea*, *Chamaejasme*, and *Laggeri*, several dwarf species of *Alyssum* and *Iberis*, and there are a good many more. Pots or pans containing these may be grouped together in an open sunny spot, and plunged in sand or coal-ashes, in a rough frame made for them, so that the lights may be not more than three or four inches above the pots. These lights should be removed in the daytime when the weather is fine, and air should be admitted, according to the temperature, at night. Such a sheet of elegant beauty, lasting, if well ranged, through February, March, and April, may be obtained in this way that I often wonder why amateurs attempt to flower early alpiners in any other fashion.

‘With me April is the earliest month in which I can expect to have anything gay on the open rockery without disappointment. I am obliged to disfigure the slopes with sheets of glass and handlights to preserve through winter at all *Omphalodes Luciliæ*, *Onosma tauricum*, *Androsace sarmentosa*, and others which cannot endure winter wet, and the real pleasure of the rockery begins when the frame alpiners are waning. I recommend those masses of covered pots in early spring to all cultivators of alpiners.

‘**Alpiners on Walls.**—A few years ago I was driving through Dorking, and I noticed a smooth and by no means ancient brick wall covered, above the reach of boys’ hands, with *Erinus alpinus*. Rough stone walls I had often seen well clothed with alpiners, but from that time I became aware that there is hardly any garden wall, of whatever material, of which the parts otherwise bare might not be made ornamental with flowers. I do not suggest that such things should supersede climbing Roses and wall-fruit, but how often we see bare walls on which nothing is grown at all! The capabilities of rough stone walls for growing mountain plants are very great. Falls of *Aubrietia* and *Iberis*, groups of *Saxifraga*, and similar subjects may make many a corner gay instead of bare. Some very pretty things I grow on walls which have defied all my attempts to cultivate them elsewhere. I may specify *Lychnis Lagasceæ*, a fragile evergreen plant of shrubby growth, easily multiplied by seed, which alternate snows and thaws generally

crush up, but in this way it continues to thrive, and is covered during early summer with crimson flowers.'

LIST XI

Selection of Alpine and other Plants suitable for the Rock Garden

Those marked with an asterisk (*) make suitable carpets or masses of green on the surface of the soil.

- **Acæna microphylla*, p. 381.
Acantholimon glumaceum, p. 601.
 **Achillea*, vars., p. 528.
Aconitum Napellus, p. 163.
Actæa spicata, p. 164.
Æthionema, vars., p. 216.
 **Alchemilla alpina*, p. 381.
Alyssum maritimum, p. 210.
 montanum, p. 210.
 pyrenaicum, p. 211.
 saxatile, p. 211.
 serpyllifolium, p. 211.
 spinosum, p. 211.
Andromeda, p. 578.
Androsace, vars., p. 621.
Anemone, vars., p. 139.
 **Antennaria*, vars., p. 507.
Anthemis Aizoon, p. 530.
Anthyllis montana, p. 334.
Antirrhinum, vars., p. 710.
Aquilegia pyrenaica, p. 157.
 **Arabis albida*, p. 205.
 androsacea, p. 206.
 mollis, p. 206.
 procurrens, p. 206.
 rosea, p. 206.
Aralia, vars., p. 469.
 **Arenaria*, vars., p. 259.
Armeria, vars., p. 603.
Arnebia echioides, p. 680.
Artemisia frigida, p. 538.
Arundo Donax, p. 958.
Asperula odorata, p. 487.
Aster alpinus, p. 501.
Astragalus monspessulanus, p. 343.
 **Aubrietia*, vars., p. 208.
Azalea sinensis, p. 595.
Bambusa, dwarf kinds, p. 968.
Bellis cærulescens, p. 498.
Berberis Darwini, p. 181.
 empetrifolia, p. 181.
 stenophylla, p. 182.
Bulbocodium, p. 377.
Buxus, vars., p. 783.
Calandrinia umbellata, p. 262.
Callitriche involucrata, p. 276.
 pedata, p. 276.
Calystegia dahurica, p. 684.
 pubescens pl., p. 684.
Campanula abietina, p. 563.
 Allioni, p. 563.
 cæspitosa, p. 563.
 ,, *alba*, p. 563.
 Elatines, p. 564.
 fragilis, p. 564.
 garganica, p. 564.
 isophylla, p. 565.
 Mariesii, p. 559.
 portenschlagiana, p. 567.
 pulla, p. 567.
 Raineri, p. 567.
 rotundifolia, p. 568.
 waldensteini, p. 569.
 &c. &c.
Cerastium Biebersteini, p. 258.
 grandiflorum, p. 258.
 tomentosum, p. 259.
Chimaphila, vars., p. 598.
Choisya ternata, p. 296.
Clematis (the new varieties of the *lanuginosa* section, and many species), p. 131.
Colchicum, vars., p. 875.
Convolvulus arvensis, p. 685.
 mauritanicus, p. 685.
Cornus canadensis, p. 474.
Coronilla iberica, p. 345.
 varia, p. 345.
Cotoneaster horizontalis, p. 410.
 integerrima, p. 410.
 microphylla, p. 411.
 thymifolia, p. 411.
Cratægus Lalandi, p. 409.
Crocus, vars., p. 936.
Cyananthus lobatus, p. 560.
Cyclamen, vars., p. 626.
Cypripedium, vars., p. 892.
Cytisus kewensis, p. 331.
Cytisus purpureus, p. 332.
Daphne blagayana, p. 777.
 Cneorum, p. 778.
 fioniana, p. 778.
 rupestris, p. 778.
 **Dianthus alpinus*, p. 239.
 ,, *cæsius*, p. 239.
 deltoides, p. 244.
 Knappi, p. 245.
 neglectus, p. 245.
 petræus, p. 245.
 &c. &c.
Diotis maritima, p. 530.
Diplopappus chrysophyllus, p. 509.
 **Draba*, vars., p. 211.
Dracocephalum, vars., p. 751.
Dryas Drummondii, p. 374.
 octopetala, p. 374.
Edraianthus tenuifolius, p. 559.
Empetrum nigrum, p. 805.
Epigæa repens, p. 578.
Epilobium orbiculatum, p. 452.
Erica, vars., p. 580.
Erinus alpinus, p. 723.
Erodium, vars., p. 287.
Erpetion, vars., p. 229.
Erythræa diffusa, p. 651.
Erythronium, vars., p. 869.
 Euonymus radicans var., p. 302.
Euphorbia Myrsinites, p. 783.
Fragaria indica, p. 376.
Fritillaria, dwarf vars., p. 857.
Galanthus, vars., p. 906.
Gaultheria, vars., p. 575.
Genista andreaana, p. 332.
 germanica, p. 329.
 pilosa, p. 329.
 sagittalis, p. 329.
 tinctoria, p. 329.
Gentiana, vars., p. 652.
 **Geranium argenteum*, p. 285.
 cinereum, p. 286.
 subcaulescens, p. 285.
Geum minimum, p. 374.
Globularia, vars., p. 738.

- **Gypsophila cerastioides*,
p. 248.
repens, p. 249.
- Haberlea rhodopensis*, p. 731.
- Hedera*, vars., p. 471.
- Helianthemum*, vars., p. 226.
- Helleborus*, vars., p. 152.
- **Herniaria glabra*, p. 761.

ORNAMENTAL AND FLOWERING TREES AND SHRUBS

ONE can hardly imagine a garden of any size which does not contain a flowering or ornamental tree or shrub of some kind or another. And yet until comparatively recent years the cultivation of this particular class of plants was more or less neglected, while a vast amount of time and labour was spent on that gaudy and ephemeral work known as 'carpet-bedding.' Fortunately, a more rational and natural view of plants in general is now taken, and there is no part of a garden which is not eminently suitable for the cultivation of some plant or another, either native or exotic, and whether tree, shrub or herb.

In the British Islands we are of course confined to the cultivation of those kinds of trees and shrubs which are natives of temperate climates like our own, but a perusal of the list given below will show that there are already a very considerable number which can be grown successfully in various parts of the kingdom. They come from all parts of the world, from China and Japan, North and South America, Europe, Asia and New Zealand, and with few exceptions they adapt themselves to our climate with the greatest ease. A visit to Kew Gardens at any season of the year will give some idea of the great beauty and variety of the trees and shrubs which may be used to beautify the landscape.

Planting for Effect.—The arguments used in favour of massing herbaceous plants in borders apply with equal force to the planting of flowering shrubs, but not to large trees. The latter, on account of their size, are best planted in advantageous positions so that they will give the best possible effect to the landscape. Shrubs, on the other hand, which grow from two or three to ten or twelve feet high—like Dogwoods, Forsythias, Cotoneasters, Diervillas, Mock Orange, Viburnums, Andromedas, Azaleas, Rhododendrons, Barberries, Ceanothus, Dabœcia, Deutzias, Ericas, Spiræas &c.—may be grown in masses on the lawn, in the pleasure ground, or wilder parts of the garden.

In what is usually called the 'shrubbery' many choice shrubs are spoiled and distorted by being crammed in anyhow, as if the chief object of the planter was to hide the ground altogether, and prevent any chance of the plant's natural development. They are pushed away in holes and corners under large overhanging trees, and often smothered with the vigorous-growing Snowberry (p. 481), and when by chance they survive, they only manage to stretch forth a lean and almost leafless branch to obtain a little sunshine.

Even in shrubberies, plants would look much better in groups or masses not too close together; and as much thought and attention should be given to the soil and position in which they are placed as one would bestow on choice fruit trees, Roses, or rock-plants.

Planting.—Trees and shrubs are usually best planted in the autumn when the sap is in a more or less quiescent state. Many, however, which do not begin to grow until the usual time in spring may be planted up to the end of February. Mild open weather should always be chosen for performing the work, and the soil should be in a dryish and easily workable condition. If the ground is covered with frost or snow, the work is best suspended until a more favourable opportunity presents itself. The actual planting itself should be done as carefully as if a fruit tree were being placed in the soil. The operation is explained at p. 1032, to which the reader is invited to turn.

Pruning and Training Ornamental Trees.—If there were no more trouble taken over the pruning and training of fruit trees than is usually taken over that of flowering trees and shrubs, the fruit garden would not only very soon present a neglected appearance but also show a big falling off in the returns of the fruit crops. All our Apples, Pears, Plums, Cherries &c. are more or less regularly attended to in the matter of training, pruning, thinning out &c.; but their cousins, which are valued chiefly for their beautiful flowers and ornamental appearance, are often left to look after themselves, sometimes maybe for years, until they almost cry out for some little attention to be given them.

Matters, however, in this respect are gradually becoming better, and trees and shrubs, other than those grown for their fruits, are receiving a proper share of attention in the way of training and pruning. The chief principles of pruning are the same as detailed for fruit trees at p. 1031. There is, however, far more variety in trees and shrubs, and the gardener should exercise his intelligence when dealing with any particular species. Its nature may be readily gleaned from its relation to others with which he may be well acquainted. Being arranged in botanical families in this book, that will still further aid him in his practical work. For instance, all the Hawthorns (*Cratægus*, p. 408), Almonds (*Prunus*, p. 356) &c. in the main follow the same principles of growth as other trees in the Rose Order (p. 355), such as Apples, Pears, Plums, Cherries &c., and require almost the same kind of pruning—due attention being given to the special peculiarities of any particular species.

As a general rule the main point is to keep up a good supply of the younger wood, and gradually cut away the old and useless branches. On the branches that are left there are usually two kinds of buds, some

plumper than the others, and these are generally the ones that produce the flowers. As the proper time for pruning is mentioned under each class of plants described it is unnecessary to discuss the matter further here.

The way in which cuts are to be made when pruning fruit trees is explained and illustrated at p. 1033. It will be noticed, however, that the buds on most of the branches are arranged not exactly opposite each other, but usually in an alternate manner so that there is little danger of injury to the buds when making a cut. In some trees, however, like the Lilac (fig. 134), the Ash (fig. 135), Forsythias, and many others, the buds are usually arranged opposite each other as shown in the sketches. In such cases, when pruning, the branch should be cut where the buds or joints are not situated exactly opposite each other. In fig. 135 of the Ash taken from nature the thin transverse lines show where a shoot may be cut across so as to leave the bud immediately beneath the cut to develop and carry on a branch almost in line with that below it, and thus add to the symmetry of the tree.

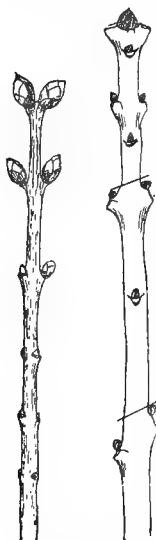

FIG. 134. LILAC.
FIG. 135. ASH.

The following is a list of the best trees and shrubs worth growing in the open air either for their beautiful flowering qualities, or their ornamental appearance. The generic name only is given, as the species follow in alphabetical order at the pages indicated.

It often happens that a list of ornamental trees and shrubs that bloom at any particular period of the year is required, and to supply this want an asterisk (*) has been placed after the names in the list to show the months when plants belonging to any particular genus may be found in blossom. As might be naturally expected, there are a very large number of trees and shrubs in bloom during April, May, June, and July, but it will also be seen that every month in the year has some particular plant in blossom. By means of the list, therefore, it will be possible to make a selection so as to have flowers in the border or shrubbery all the year round. It may be noted that species are not mentioned, but a reference to the page given after each genus will enable the reader to find what species belonging to it bloom during the months under which an asterisk appears.

It may also be remarked that many trees and shrubs are more remarkable for their beautiful bright coloured berries, rather than their blossoms, such as Aucubas, Euonymus, Pernettyas, Sea-Buckthorn, Skimmias, while many others are remarkable for both flowers and fruit, such as the Cherries, Cotoneasters, Barberries, Hawthorns, Med-

AUTUMN TINTS

While the spring-time is remarkable for the beautiful and brilliant greens of the foliage of the numerous trees and shrubs which have awakened from their winter sleep, the autumn is no less remarkable for the great change of colouring that has come over this same foliage. In a few short months from May to October, the leaves have been hard at work assimilating food and building up the tissues of the plants. When they burst from their protecting winter buds, either from the branches or the seeds, they proceed to perform their natural functions with the greatest energy. But as the hot summer approaches, and then the autumn with its shorter days, the energy of the protoplasm (see p. 22) within the cells gradually subsides and ultimately ceases altogether in the case of those leaves which are termed 'deciduous,' or that remain on the branches but one season.

It is unnecessary to dilate here upon the scientific reasons as to the falling of the leaves in autumn; but it may be remarked that all the food manufactured for the plants is not wasted by the dropping of the foliage. Before this it has been drafted down the stems and to the roots in the case of perennials and root crops by means of the fibre bundles referred to at p. 30 as composing the main nerves and veins

of the leaves. During the process of withdrawal a change in colour comes over the foliage. The more or less brilliant greens are gradually replaced by yellow, orange, red, purple, and a variety of intermediate shades until most beautiful pictures are produced upon the landscape by this autumnal colouring. The masses of gold presented by the stately Elms, the deeper amber yellow of the Horse Chestnuts, the beautiful russety-brown of the Beech and Oaks, the purple-red of the Virginia Creeper, and the tints of all our native trees and shrubs are sufficiently well known and never fail to call forth our admiration during the autumn. But there are many other trees and shrubs natives of other climes quite as remarkable for their vivid colouring at this period, and they are well worthy of a place in gardens where they can be grown to produce an effect in conjunction with the various hues of the numerous evergreens of the Conifer Family, the Common Holly &c. It has been noticed in connection with autumn colouring that leaves covered with hair or down undergo but very little change in colour, and it therefore looks as if the change in the cells was due to the light. While all deciduous trees and shrubs are more or less beautiful in the colouring of their foliage in autumn, some are particularly fine and deserve especial mention in the following list. The name of the genus only is mentioned, as the species can easily be found at the page referred to after the name.

LIST XIII

Trees, Shrubs, and Climbers remarkable for the Autumnal Colouring of their Foliage

Acer, p. 313.	Corylus, p. 797.	Prunus, p. 356.

HARDY WATER AND BOG PLANTS

It is only of late years that any particular attention has been given to seriously utilising pieces of water in gardens. The common white Water Lily (p. 186) and the yellow Brandy Bottle (p. 185) were looked upon more or less as beautiful aquatic weeds. But the numerous hardy and brilliantly coloured hybrids that are now in cultivation (see p. 187) have revolutionised former ideas in regard to the use of water in the garden, and have served to call attention not only to Water-Lilies but to many other ornamental plants which may be grown with advantage either in water or on its banks.

The following is a list of the best water and bog plants. The descriptions, cultural information &c. will be found at the pages given after each name.

LIST XV

A Selection of Ornamental Water and Bog Plants

 Ranunculus aquatilis, p. 147.

Ranunculus Lingua, p. 149.
 Richardia africana, p. 955.
 Rumex Hydrolapathum,
 p. 768.
 Sagittaria sagittifolia fl. pl.,
 p. 806.

Scirpus lacustris, p. 972.
 Sparganium, vars., p. 953.
 Stratiotes aloides, p. 883.
 Thalia dealbata, p. 884.
 Typha in var., p. 953.
 Water Lilies, p. 186.

A Selection of Plants thriving in Marshy or Boggy Ground

Arundo Donax, p. 958.
 Bamboos, Hardy, p. 964.
 Botomus umbellatus, p. 806.
 Calla palustris, p. 955.
 Caltha, vars., p. 150.
 Carex pendula, p. 971.
 Chrysobactron Hookeri,
 p. 826.
 Coptis trifolia, p. 154.
 Cornus canadensis, p. 474.
 Crinum capense, p. 911.
 Cypripedium spectabile,
 p. 893.
 Dodecatheon Jeffreyanum,
 p. 626.
 Meadia and var.
 alba, p. 626.
 Drosera, vars., p. 444.
 Eomecon chionantha, p. 195.
 Epilobium album, hirsutum,
 &c. p. 451.
 Eupatorium, vars., p. 494.
 Galax aphylla, p. 600.
 Gentiana Pneumonanthe,
 p. 655.
 Gunnera scabra, p. 446.
 Helonias bullata, p. 878.
 Houttuynia californica,
 p. 774.
 cordata, p. 774.
 Iris foetidissima, p. 922.
 fulva, p. 923.
 graminea, p. 923.
 Kämpferi, p. 925.
 Monnieri, p. 927.
 ochroleuca, p. 927.
 Pseudacorus, p. 929.

Iris sibirica, p. 931.
 Juncus spiralis, p. 882.
 Leucanthemum lacustre,
 p. 534.
 Leucocjum æstivum, p. 908.
 Hernandezii,
 p. 908.
 Liatris pycnostachya, p. 495.
 spicata, p. 495.
 Lilium canadense, p. 845.
 carolinianum, p. 856.
 pardalinum, p. 853.
 superbum, p. 856.
 Linnæa borealis, p. 482.
 Lobelia cardinalis, p. 556.
 Lychnis Flos-Cuculi fl. pl.,
 p. 256.
 Lysimachia clethroides,
 p. 629.
 Nummularia,
 p. 629.
 thyrsiflora,
 p. 630.
 vulgaris, p. 630.
 Lythrum, vars., p. 450.
 Monarda didyma, p. 750.
 Myosotis palustris, p. 678.
 Nierembergia rivularis,
 p. 6
 Nyssa aquatica, p. 476.
 Orchis, vars., p. 891.
 Osmunda palustris, p. 1022.
 regalis, p. 1022.
 Oxycoccus, vars., p. 573.
 Parnassia, vars., p. 428.
 Phormium tenax, p. 816.
 Pinguicula, vars., p. 728.

Polygonum compactum,
 p. 769.
 Sieboldi, p. 769.
 Primula denticulata, p. 607.
 farinosa, p. 608.
 involucrata, p. 610.
 japonica, p. 610.
 Munroi, p. 610.
 Parryi, p. 613.
 Reidi, p. 614.
 rosea, p. 615.
 sikkimensis, p. 616.
 Pyrethrum uliginosum,
 p. 535.
 Rhexia virginica, p. 449.
 Rodgersia podophylla, p. 415.
 Sagittaria, vars., p. 806.
 Samolus littoralis, p. 632.
 Sarracenia purpurea, p. 189.
 Saxifraga Hirculus, p. 421.
 peltata, p. 424.
 Scirpus zebrina, p. 972.
 Senecio pulcher, p. 542.
 speciosus, p. 543.
 Spigelia marilandica, p. 649.
 Spiræa Aruncus, p. 364.
 astilboides, p. 364.
 kamtschatica, p. 364.
 palmata, p. 365.
 Ulmaria, p. 365.
 Swertia perennis, p. 657.
 Symlocarpus foetidus,
 p. 955.
 Thalictrum anemonoides,
 p. 138.
 flavum, p. 138.
 Tradescantia virginica,
 p. 807.

LAWNS

ALL other things being equal, there is nothing that lends a greater charm and repose to a garden than a well-kept lawn. Where such exists it should always be carefully attended to, as once a lawn is allowed to become wild, it takes a long time to bring it back to a really good condition.

In the pages of this work many plants are mentioned as being suitable for lawn decoration. It must not, however, be taken for granted that each and every plant thus mentioned is to be grown on the lawn. It would be far better to leave the lawn quite free from all except its natural vegetation than to spoil it by dotting groups of plants, or solitary specimens, all over it in a meaningless kind of way. The lawn should not be treated as if it were an orchard or a shrubbery, and anything that tends to interfere with its repose, or jars upon the taste, is to be avoided.

Making a Lawn.—Lawns are made in two ways—either by sowing seed or laying turf. Both ways are good, but some have a preference for one rather than the other. When a lawn has been made by sowing grass it takes about three years before a really good foundation has been made, and during that period numerous rollings, cuttings, and waterings must have been given. The advantage of making a lawn with turf is that a good one can be obtained practically in one season—with the aid of frequent cuttings, rollings, and waterings. If the turf is good and free from weeds it is on the whole a better and quicker method of producing a lawn.

Whether seeds or turf are used, the first and all-important point is to have good soil with a surface properly levelled and quite free from hillocks and hollows, however slight. The soil should be well dug and manured and afterwards trodden down with the feet, or rolled; but the roller should not be too heavy—one weighing about one cwt. will be sufficient, or the ground will be pressed into a caked condition, more or less impervious to the passage of water.

Levelling.—This is readily accomplished by means of a spirit level attached to the edge of a level board. Special implements are used for the purpose, but a stout quadrangular pole, about 8 ft. (or half a rod) long will do equally well, provided its edges are perfectly level.

Where the lawn is to be of some size, wooden pegs must be driven into the soil at such intervals that the levelling rod can reach from one to the other. Having fixed one peg at what is to be the ultimate height and level of the lawn, all other pegs must be fixed or driven into the soil until the top of each peg is on a level with that of the next. This can be easily ascertained by means of the spirit level.

The ground itself should also be carefully gone over with the level, resting the rod in all directions with a view to finding any risings or depressions. Where such occur they must be reduced or filled up by means of the rake until the entire surface is as flat and as level, but not necessarily as smooth, as a billiard table.

This point having been reached, and the soil having settled down properly, seeds of the best lawn grass may be sown during mild showery weather in March or April, as it then germinates in a very short time. Seeds may also be sown under similar circumstances in September, so that the seed shall germinate and the young grass become established before the setting in of winter.

To ensure a thick and even sward, from 60 to 80 lbs. (or 3-4 bushels) of grass seed will be required to sow an acre of ground. The seed should be sown broadcast and as evenly as possible. The soil is afterwards raked over lightly and a light roller may also be used to bring the seeds and soil in closer contact, and give a finish to the work. If the weather is not showery, a good watering is also necessary and may be repeated from time to time if necessary.

When the grass has grown sufficiently long, it should be cut with a scythe—not with a mowing machine, as the latter is apt to tear roots and all up at first. It is as a rule safer to have the first few cuttings done with a scythe, so that the grass may become strong and tufted, and thus better able to stand the mowing machine afterwards.

When turf is used, the chief point to remember is : keep the surface level. Each turf is about 3 ft. long, 1 ft. wide, and an inch or so thick. The thickness, however, varies a good deal, and where thin turves are used a little fine soil should be placed beneath to bring them to the proper level. As three turves go to a square yard it is easy to estimate the number required for any particular piece of ground. The turf cutters, however, generally cut a shade under rather than over the dimensions, and it is therefore always safer to have a few extra ones in case of necessity.

When the turves have all been laid down neatly edge to edge, a little fine soil is sprinkled over the surface, and brushed into the crevices. The whole surface may then be thoroughly beaten with a turf beater (a thick flat-faced piece of wood, with a long handle let in obliquely in the centre at the back) so as to reduce any slight inequalities. Failing this, beating the turf with the back of a strong spade will be almost equally efficacious. The first cuttings should be done with a scythe, and frequent rollings and waterings will soon make a fine greensward.

General Treatment.—Once well established, a lawn should never be neglected. If looked after regularly, it will last in good condition for years, but if not, it will in the course of a few years show signs of wearing out.

Weeding.—This should be done regularly in spring and autumn so as to keep such plant pests as *Plantain*, *Daisies*, *Dandelions*, and other

weeds down. Frequent cutting with the machine will prevent them flowering and ripening seed. Where, however, they take a strong hold they may be eradicated by dropping a little vitriol (sulphuric acid) or arsenic down the centre of each with a pointed skewer. The latter should be pushed down into the weeds, as some of them have tap-roots which, unless killed, will throw forth other shoots after the first ones have been destroyed. An intelligent lad can do this work easily, but great care must be taken in using the poison.

Where the use of poison is feared or disliked, the only safe way to destroy weeds on lawns is to grub them up with an old knife or 'daisy-grubber.' It takes a long time, but if done systematically is very effective. An excellent plan is to strain two white lines about 2 feet apart on the grass and proceed to root up all the weeds between them. In this way the work is done systematically and in such a narrow space there is little chance of overlooking the weeds. When one portion has been cleaned, one line may be taken up and stretched 2 feet from the other on the opposite side, proceeding with the work in the same way.

Manuring Lawns.—In the course of time the grass will begin to look poor, and lack vigour and freshness in growth, unless it has some plant food put into the soil in some way. Covering the lawn with short well-rotted manure is practically out of the question in most cases, owing to its unsightliness. Liquid manures of cow-dung, guano, sulphate of ammonia &c. may, however, be given at frequent intervals, care being taken that they are not too strong, otherwise the grass may be 'burnt' and present a brownish appearance. About 6–8 lbs. of basic slag and 3–4 lbs. of kainit, mixed together, may be used in the autumn or winter months, and will sprinkle over about 40 square yards. About 3 or 4 lbs. of superphosphate of lime will also cover the same area and may be applied, not with the basic slag and kainit, but the following spring. Rape-dust or fine bone-meal at the rate of about 4 lbs. to about 40 sq. yds. may also be used.

Mossy Lawns.—Moss-covered lawns are very unsightly, and sometimes very difficult to clean. The moss should be well raked out with a good rake in moist weather during the autumn. The lawn should be gone over in two or three different directions, and although the grass will have the appearance of being torn up by the roots, it will in reality be injured very little. After being well cleared of moss, some fine rich soil and wood ashes may be strewn over the surface, and a little basic slag and kainit, as recommended above, may also be added. The surface is then levelled and lightly rolled. In spring any vacant spot should be sown with grass seed, so as to bring the whole surface into a green state.

Renovating old Lawns.—Where lawns, notwithstanding every care, show unmistakable signs of decay, there is only one thing left to be done. That is to lift the turf in autumn, and give the soil beneath a thorough digging and manuring as if about to lay turves in the first place. After the preparation and levelling of the soil in the way indicated above, the turves may be replaced, beaten down and rolled, and receive the same treatment generally as a newly made lawn.

LIST XVI

Ornamental Plants suitable for large Lawns, Parks &c., and for Subtropical Gardening

Abutilon, p. 278.	Cordyline australis, p. 822.	Paulownia, p. 712.
Acanthus, p. 736.	Cortaderia, p. 960.	Phormium tenax, p. 816.
Agave, p. 916.	Eucalyptus globulus, p. 447.	Phyllostachys, p. 969.

Cineraria maritima, p. 541.	Musa Ensete, p. 888.	Zea Mays, p. 964.

GARDEN WALKS AND PATHWAYS

WHILE it is an excellent thing to have beautiful Lawns, Flower Borders, Rock Gardens, and patches of Fruits and Vegetables in a garden, it is no less excellent to be able to reach any or all of these particular spots by means of pleasant walks, paths, or roadways. In designing any garden, therefore, it is a matter of the greatest importance to allow a proper amount of space for walks and pathways. Whether these are perfectly straight or more or less curved, wide or narrow, will depend a good deal upon individual taste and the size of the garden. Some people seem to have a mania for making walks in every possible place, and this results in cutting the surface of the garden up into a kind of patchwork, with little triangles here, circles there, horse-shoes, rectangles, and many other fantastic and useless shapes for flower beds &c. dotted about here and there. As few footpaths as possible should be in the garden, and space given only to those absolutely necessary. This will not only allow of more space for flowers, fruit, or vegetables, but will not necessitate so much labour in the up-keep of the pathways.

Gravel Paths.—As these are undoubtedly the most important, it is necessary that they should be well made at first, as nothing will give so much trouble and inconvenience afterwards as badly constructed gravel paths. The main object in making a good pathway is to secure a firm and pleasant surface for walking upon in all weathers and seasons. The surface should be such that it will not work up into large pebbles in summer or sticky mud in winter. Pathways should always have a gentle slope away from dwellings or other buildings, and the highest point should be a few inches at least below what builders call the ‘damp course’ in houses.

Drainage.—To secure a good pathway it is first of all necessary to consider the question of drainage, and also the nature of the soil beneath the surface. In wet heavy soils the drainage requires to be in a more perfect condition than when walks are constructed on a gravelly bottom. At p. 44 the drainage of flower-pots &c. for sowing seeds has been mentioned. Almost precisely the same principle must be carried out with pathways. In heavy soils there should be 1–2 ft. of old brickbats, rubble, clinkers &c. well rammed down and made perfectly hard without being mixed with any finer materials. Above this layer some finer rubble, stones, clinkers &c. may be placed and also rammed down firmly and evenly. This will give a perfectly porous layer between the surface and the soil beneath, and if the drainage is to be made still more perfect, as is often necessary with important walks and drives in public gardens, provision must be made at first to have drain pipes laid at the sides to receive the surface water in times of heavy rain or sudden downpours. The drainage having been made perfect, the surface may then be covered 2–4 in. deep—more or less—with the best yellow gravel. Care must be exercised in selecting this, as some kinds have far too much clayey matter, and others too much sand and grit, to bind properly when rolled. What is technically known as ‘hoggin’ in the London neighbourhood is an excellent gravel for pathways. It binds well, has a good colour, and when properly rolled down and watered gives a neat and finished appearance to the garden. In some large parks and gardens the gravel walks are covered with ground shells. These make a good surface for walking on in dry weather, although at first the colour is somewhat trying to the eyes, and in wet weather they are not an improvement on good gravel. Pathways made of gravel should have a slightly convex top, so that the sides slope gently away from the centre. This will throw the rain off towards the sides, and give a good foothold in the centre, even in very wet weather, on well-constructed pathways.

Weeding &c.—Pathways, like lawns, require constant attention to keep them free from weeds and neat in appearance. It becomes

necessary occasionally to have the surface pricked up all over, and raked into proper positions so as to get rid of any hollows caused by wear and tear. Frequent rolling is also necessary to keep a good surface. Weeds if not eradicated by the hoe or hand may be destroyed by one of the many weed killers now on the market. Great care should be exercised in using these, and the instructions given by sellers may be followed out to avoid accidents to other vegetation and animals.

Asphalt Paths.—Of late years Asphalt as used for making pavements has been used a good deal for garden paths, and when well made they seem to be very satisfactory, especially between tiled edgings. They have a smooth and agreeable walking surface in all weathers, and when constructed with a slightly convex surface—arching from the centre to the sides—the rain is readily drained away. They have another advantage in being nearly always quite free from weeds. This is a double-barrelled boon—it saves labour and the cost of weed-killers. Notwithstanding these advantages, however, the gravel pathway still holds its own in most gardens, chiefly perhaps on account of its colour, and because when the grass edgings adjoining asphalt paths are cut they leave a conspicuous narrow border of soil between the asphalt and the turf; and asphalt cannot be so readily laid as gravel to cover unsightly spaces.

Grass Walks.—There is nothing to equal the pleasure derived from walking on a beautiful greensward, whether it be a well-kept lawn or an alley between the flower borders. In small gardens it may be, and of course is in many cases, impossible to have grassy walks; but in large parks and gardens many parts now covered with gravel might be more appropriately covered with grass.

A visit to the Royal Gardens, Kew, will give one a good idea of how well grassy avenues, vistas, and pathways may be made, and how beautiful they look between the trees, shrubs, and flower beds. Years ago a long vista from the Palm House to the banks of the Thames facing Syon House was an ugly and very pebbly broad walk which no one ever walked upon unless obliged to by wet weather. The gravel, however, has vanished, and the greensward has taken its place, much to the advantage of the gardens and the comfort of visitors. This might be imitated with advantage in other gardens. The only disadvantage a grass walk can have is in wet weather, but at such a time there is but little inducement to use pathways at all—whether gravel or grass—only in the case of necessity. The short time during the year that grass may be unfit to walk upon should not, however, prevent its being used when possible for walks during the greater portion of the year.

CLASSIFICATION OF PLANTS

IT is a natural and almost unconscious process to place any two or more plants similar in appearance and character into the same group and say that they are more or less closely related, although they differ from each other in minor details. This is practically classifying plants according to their relationship to each other into natural groups, and by such a process the gardener is enabled to deduce many points that may be of importance to him in the actual work of cultivation.

It would, for instance, be a very poor observer indeed who could not *see* the difference between, say, a Buttercup and a Lily, but it might be somewhat difficult for him to explain in words exactly the points wherein they differ. Just imagine for a moment a person who had never seen a Buttercup or a Lily asking what they were and how he was to distinguish one from the other, and some idea will be gained as to the difficulty in giving the information in such a way that the Buttercup or Lily will not be mixed up with an Orchid, or a Rose, or a Tulip, or any other plant.

When plants are so common that they are grown by almost everybody, their general features or characteristics become impressed on the mind, and the names which botanists have given them usually come tripping off the tongue with ease. But when a strange plant appears without a name, an effort is at once made, almost unconsciously, to place it near some plant already known. The roots, stems, leaves, flowers, fruits &c. are carefully and critically examined and compared one by one, and the plant is said to come near such and such a species but differs from it in many respects.

If the cultivator of such a plant has even only a slight knowledge of the way in which plants have been grouped more or less naturally by botanists, he may, by the aid of his books, run the unknown plant very close, if not quite, to its own group, from the characters he sees. But if his books have the plants arranged simply in alphabetical order according to their names and not according to their relationship, he may as well give up his search at once, unless he has the time and inclination to wade through every name from A to Z. Indeed, descriptive plant-books arranged in purely alphabetical order are only of value when the *proper name* of the plant about which information is required is already known. This is a *sine qua non* to the use of such books. 'To call a Rose by any other name' would in such cases probably lead to unlooked-for and perhaps not altogether satisfactory results when the cultural details came to be applied.

For these reasons chiefly, and also because the majority of amateurs often find a difficulty in remembering the botanical names of plants, it has been considered best to have the plants described in this work arranged in their natural groups or Orders, so that in the event of a cultivated plant being nameless, it may with very little trouble soon be found by means of the 'Key' given below. Where the name of a plant is already known, a reference to the Index at the end of the work will at once give the page at which description, culture, propagation and other information may be found concerning it. The amateur and the professional gardener will both find it an excellent and interesting proceeding, however, to try to place or determine any particular plant into its proper group by means of examining the characters of the flowers, leaves, stems, roots &c.

The 'Key' to the natural Orders of Plants described in this work will be found useful in trying to place a plant whose name is unknown in its proper group, and, it is hoped, will ultimately lead to its identification. Although an attempt has been made to dispense as far as possible with botanical or technical terms, the use of some was unavoidable. Such terms will be found explained in the Illustrated Glossary at p. 1.

KEY to the NATURAL ORDERS of PLANTS described in this work

The Vegetable Kingdom may be divided into two Great Groups or *Sub-Kingdoms*, namely:—

I. FLOWERING PLANTS, or PHANEROGAMS.

These are trees, shrubs or herbs with more or less conspicuous flowers provided with stamens and pistils in the same or separate flowers, and seeds containing a distinct embryo, as in annuals and biennials, herbaceous plants, trees, shrubs &c.

II. NON-FLOWERING PLANTS, or CRYPTOGAMS.

These include the FERNS (*Filices*), HORSETAILS (*Equisetum*), CLUBMOSSES (*Lycopodium*), MUSHROOMS (*Agaricus*), and all the lower vegetable organisms.

Flowering Plants (or Phanerogams) are divided into Two *Classes*:—

(i.) **ANGIOSPERMS.**—This group includes all the flowering plants popularly known as annuals, biennials, herbaceous perennials and trees and shrubs, described in this work from p. 131 to p. 972. They are characterised by having roots, stems, leaves, and flowers, and have their seeds enclosed or hidden in an ovary,

seed vessel, or fruit. It is this latter characteristic that gives the name to the group, the word 'angiosperm' being derived from 'angios,' hidden, and 'sperma,' a seed.

(ii.) **GYMNOSPERMS.**—In these plants the flowers are strictly unisexual, that is either all female or all male, and the perianth, ovary, and styles are absent. The ovules are naked (not enclosed in carpels), and are fertilised by direct contact with the pollen, and not by means of a pollen tube (see p. 24).

Cotyledons (seed-leaves) 2, or sometimes in whorls of 3 or more.

Natural Orders with these Characters.—**GNETACEÆ**, p. 972, **CONIFERÆ**, p. 972.

The Angiosperms (or plants having their seeds enclosed in an ovary) are also divided into two main groups or *sub-classes*, viz. :—

1. **DICOTYLEDONS** (p. 131) and 2. **MONOCOTYLEDONS** (p. 805), the characters of which are given below with the various groups belonging to them.

Sub-Class I. **DICOTYLEDONS** (p. 131 to p. 805).

The plants belonging to this group are described in this work from p. 131 to p. 805, and are characterised by having stems with bark, pith, and wood, and when perennial, increasing in diameter by an annual layer of wood added to the outside of the old wood, and another of bark to the inside of the old bark. Leaves usually with netted veins. Flowers with the parts usually in fours or fives, and usually with a distinct perianth. Ovules in closed carpels, through the tissues of which the pollen tube passes to effect fertilisation as described at p. 24. Embryo with 2 cotyledons or seed leaves.

Dicotyledons are subdivided into 3 main divisions, viz. :—1. *Poly-petala*; 2. *Disciflora*; and 3. *Calyciflora*, each of which is again subdivided into series, cohorts, and natural orders as below.

Division I. **POLYPETALÆ** (p. 131 to p. 477).

Flowers with both calyx (sepals) and corolla (petals). Petals free or distinct from each other.

Series I. **THALAMIFLORÆ** (p. 131 to p. 284).

Sepals usually free. Petals definite, often numerous. Stamens inserted on a torus or receptacle, hypogynous, numerous or definite. Carpels free (apocarpous) or united (syncarpous).

Cohort 1. **RANALES** (carpels usually free).—Stamens numerous. Perianth consisting of calyx only, or of calyx and corolla.

Natural Orders with these Characters.—**RANUNCULACEÆ** (p. 131), **CALYCANTHACEÆ** (p. 172), **MAGNOLIACEÆ** (p. 173), **ANO-**

NACEÆ (p. 177), MENISPERMACEÆ (p. 178), BERBERIDEÆ (p. 178), NYMPHÆACEÆ (p. 185).

Cohort 2. PARIETALES (placentas parietal).—Stamens numerous or definite in number. Ovary 1-celled or with spurious dissepiments. Ovules usually many.

Natural Orders with these Characters.—SARRACENIACEÆ (p. 188), PAPAVERACEÆ (p. 189), FUMARIACEÆ (p. 198), CRUCIFERÆ (p. 201), RESEDACEÆ (p. 222), CISTINEÆ (p. 223), VIOLARIBÆ (p. 227), BIXINEÆ (p. 235).

Cohort 3. POLYGALINEÆ.—Sepals and petals 5, rarely 4 or 3. Stamens equal to or twice as many as the petals or sepals. Carpels usually 2, cohering in a more or less perfectly 2-celled ovary. Flowers regular or irregular.

Natural Orders with these Characters.—PITTOSPOREÆ (p. 236), POLYGALÆÆ (p. 237).

Cohort 4. CARYOPHYLLINEÆ (placentas free central).—Sepals 2–5, rarely 6, free or united. Petals equal in number, or more, or fewer by abortion. Stamens as many as petals, or twice as many, rarely more or fewer. Ovary usually 1-celled.

Natural Orders with these Characters.—FRANKENIACEÆ (p. 238), CARYOPHYLLEÆ (p. 238), PORTULACÆÆ (p. 261), TAMARISCINEÆ (p. 264).

Cohort 5. GUTTIFERALES (stamens numerous, calyx imbricate).—Sepals 2–5, often 4 or 5, rarely numerous. Petals as many as sepals, rarely more. Ovary usually 3- or more celled. Flowers regular.

Natural Orders with these Characters.—HYPERICINEÆ (p. 265), TERNSTRÆMIACEÆ (p. 267).

Cohort 6. MALVALES (stamens numerous, calyx valvate).—Calyx lobes or sepals 5, rarely 2–4. Petals usually 5, rarely none. Stamens free or united in one bundle. Ovary usually 3- or more celled.

Natural Orders with these Characters.—MALVACEÆ (p. 270), STERCULIACEÆ (p. 280), TILIACEÆ (p. 280).

Series II. DISCIFLORÆ (p. 284 to p. 322).

Flowers regular with parts usually in fives. Calyx usually free from the ovary. Stamens often definite inserted below or above or around a disc. Ovary usually superior or immersed in the disc. Carpels usually united.

Cohort 1. GERANIALES.—Disc often beneath the stems or adnate to the staminal column, or reduced to glands alternating with the petals. Ovary entire or often lobed, or with almost free carpels.

Natural Orders with these Characters.—LINEÆ (p. 282), GERANIACEÆ (p. 284), RUTACEÆ (p. 295), SIMARUBEÆ (p. 298).

Cohort 2. OLACALES.—Disc cup-shaped or ringed, free, or bearing the stamens and petals, or divided into glands. Ovary entire. Leaves simple.

Natural Order with these Characters.—ILICINEÆ (p. 299).

Cohort 3. CELASTRALES.—Disc cushion-like or adnate to the calyx. Stamens inserted around or on the margins of the disc. Ovary usually entire. Leaves simple or rarely compound.

Natural Orders with these Characters.—CELASTRINEÆ (p. 301), RHAMNEÆ (p. 303), AMPELIDEÆ (p. 307).

Cohort 4. SAPINDALES.—Disc various. Stamens inserted beneath, above or around it. Ovary entire or often lobed. Leaves pinnate, or rarely simple or digitate. Flowers often polygamous dioecious.

Natural Orders with these Characters.—SAPINDACEÆ (ACERINEÆ) (p. 310), ANACARDIACEÆ (p. 319), CORIARIEÆ (p. 321).

Series III. CALYCIFLORÆ (p. 322 to p. 477).

Calyx tube enclosing the ovary or adnate to it. Petals in one series enclosed by the calyx tube. Stamens many or definite, inserted on the calyx tube. Ovary inclosed by calyx tube or inferior.

Cohort 1. ROSALES.—Flowers regular or irregular, often hermaphrodite. Carpels solitary or numerous, free or united at the base. Styles usually distinct. Leaves variously compound, or simple.

Natural Orders with these Characters.—LEGUMINOSÆ (p. 322), ROSACEÆ (p. 355), SAXIFRAGEÆ (p. 414), CRASSULACEÆ (p. 437), DROSERACEÆ (p. 443), HAMAMELIDEÆ (p. 444), HALORAGEÆ (p. 446).

Cohort 2. MYRTALES.—Flowers regular or nearly so, usually hermaphrodite. Ovary syncarpous, inferior or enclosed by calyx tube. Style undivided. Leaves simple, entire, rarely toothed.

Natural Orders with these Characters.—MYRTACEÆ (p. 447), MELASTOMACEÆ (p. 449), LYTHRARIEÆ (p. 449), ONAGRARIEÆ (p. 451).

Cohort 3. PASSIFLORALES.—Flowers regular or nearly so, rarely irregular. Ovary syncarpous, inferior or superior, usually enclosed by the calyx tube, 1-celled. Styles more or less divided or entire, or distinct from the base. Leaves entire, lobed, or dissected.

Natural Orders with these Characters.—LOASEÆ (p. 457), PASSIFLOREÆ (p. 459), CUCURBITACEÆ (p. 460), BEGONIACEÆ (p. 462).

Cohort 4. FICOIDALES.—Flowers regular or nearly so, with numerous petals and stamens. Ovary syncarpous, half superior or

superior, 1- or more celled. Styles free, or divided at the apex. Leaves entire, or absent on fleshy stems.

Natural Orders with these Characters.—CACTEÆ (p. 463), FICOIDEÆ (p. 464).

Cohort 5. UMBELLALES.—Flowers regular. Ovary inferior, 2- or more celled. Styles distinct or united at the base. Stamens usually definite.

Natural Orders with these Characters.—UMBELLIFERÆ (p. 464), ARALIACEÆ (p. 469), CORNACEÆ (p. 473).

Division II. GAMOPETALÆ or MONOPETALÆ (p. 477 to p. 759).

Flowers with both calyx and corolla. Petals more or less united into a 2- or more lobed corolla.

Series I. EPIGYNÆ (p. 477 to p. 571).

Ovary inferior. Stamens usually equal in number to the lobes of the corolla. Mostly herbs, often with milky juice. Shrubs in Caprifoliaceæ and a few Compositæ.

Cohort 1. RUBIALES.—Leaves usually opposite or verticillate. Stamens attached to the corolla (epipetalous). Ovary 2- or more celled, each cell with 2 or more ovules.

Natural Orders with these Characters.—CAPRIFOLIACEÆ (p. 477), RUBIACEÆ (p. 486).

Cohort 2. ASTERALES.—Stamens attached to the corolla. Ovary 1-celled, 1-ovuled.

Natural Orders with these Characters.—VALERIANEÆ (p. 488), DIPSACEÆ (p. 490), COMPOSITÆ (p. 492).

Cohort 3. CAMPANALES.—Stamens usually free from the corolla. Ovary 1- or more celled, each with 1 or many ovules.

Natural Order with these Characters.—CAMPANULACEÆ (p. 555).

Series II. HYPOGYNÆ (p. 571 to p. 759).

Ovary often superior. Stamens free from the corolla, opposite the lobes, or twice or more than twice as many in number.

Cohort 4. ERICALES.—Flowers regular, hermaphrodite. Stamens twice as many as the lobes of the corolla, or equal in number and alternate with them.

Natural Orders with these Characters.—VACCINIACEÆ (p. 571), ERICACEÆ (p. 574), DIAPENSIACEÆ (p. 599).

Cohort 5. PRIMULALES.—Flowers regular, hermaphrodite or polygamous by abortion. Stamens equal in number to lobes or petals of the corolla and opposite them. Ovary 1-celled.

Natural Orders with these Characters.—PLUMBAGINEÆ (p. 600), PRIMULACEÆ (p. 604).

Cohort 6. EBENALES.—Trees or shrubs. Flowers regular, hermaphrodite or unisexual. Stamens equal in number to, or twice as many as, or more than, the corolla lobes. Ovary 2- or more celled.

Natural Orders with these Characters.—EBENACEÆ (p. 632), STYRACEÆ (p. 633).

Cohort 7. GENTIANALES.—Leaves usually opposite. Corolla regular. Stamens alternate with the corolla lobes and equal in number, or if fewer often alternate with the carpels.

Natural Orders with these Characters.—OLEACEÆ (p. 636), APOCYNACEÆ (p. 644), ASCLEPIADEÆ (p. 646), LOGANIACEÆ (p. 648), GENTIANEÆ (p. 650).

****Ovary usually superior. Carpels 2, or rarely 1 or 3.*

Cohort 8. POLEMONIALES.—Leaves usually alternate. Corolla regular. Stamens alternate with the corolla lobes and equal in number.

Natural Orders with these Characters.—POLEMONIACEÆ (p. 658), HYDROPHYLLACEÆ (p. 666), BORAGINEÆ (p. 670), CONVULVULACEÆ (p. 682), SOLANACEÆ (p. 687).

Cohort 9. PERSONALES.—Corolla often irregular or oblique. Upper stamen smaller than the others, or often reduced to a staminode or absent.

Natural Orders with these Characters.—SCROPHULARINEÆ (p. 701), LENTIBULARIEÆ (p. 728), GESNERACEÆ (p. 729), BIGNONIACEÆ (p. 731), PEDALINEÆ (p. 734), ACANTHACEÆ (p. 735).

Cohort 10. LAMIALES.—Corolla often irregular, oblique or 2-lipped. Upper stamen often reduced to a staminode or absent. Carpels 1-ovuled or collaterally 2-ovuled. Fruit often enclosed by the calyx, indehiscent.

Natural Orders with these Characters.—SĒLAGINEÆ (p. 737), VERBENACEÆ (p. 738), LABIATÆ (p. 742).

Division III. MONOCHLAMYDEÆ, INCOMPLETÆ, or ACHLAMYDEÆ (p. 759 to p. 805).

Flowers in which the corolla is usually and the calyx often absent.

(a) Flowers hermaphrodite, or unisexual or polygamous in a few genera.

Natural Orders with these Characters.—NYCTAGINEÆ (p. 759), ILLECEBRACEÆ (p. 761), AMARANTACEÆ (p. 761), CHENOPODIACEÆ (p. 765), PHYTOLACCACEÆ (p. 766), POLYGONACEÆ (p. 767).

(b) Herbs or shrubs. Ovary apocarpous, syncarpous or monocarpous.

Natural Orders with these Characters.—ARISTOLOCHIACEÆ (p. 772), PIPERACEÆ (p. 773).

(c) Ovary usually monocarpous. Trees or shrubs, very rarely herbs. Flowers often hermaphrodite. Stamens perigynous.

Natural Orders with these Characters.—LAURINEÆ (p. 774), PROTEACEÆ (p. 776), THYMELÆACEÆ (p. 777), ELÆAGNACEÆ (p. 779).

(d) Trees or shrubs, sometimes herbs. Flowers usually strictly unisexual. Perianth calyx-like, minute or none. Ovary syncarpous or monocarpous.

Natural Orders with these Characters.—LORANTHACEÆ (p. 781), EUPHORBIACEÆ (p. 782), URTICACEÆ (p. 785), PLATANACEÆ (p. 789), JUGLANDEÆ (p. 790), MYRICACEÆ (p. 792), CUPULIFERÆ (p. 793), SALICINEÆ (p. 802), EMPETRACEÆ (p. 804).

Sub-Class II. MONOCOTYLEDONS (p. 805 to p. 972).

The plants belonging to this class have stems without bark, pith, or concentric rings, and do not increase in diameter by annual layers of wood. Leaves usually with parallel veins, but net-veined in AROIDEÆ (p. 953) and SMILACINEÆ (p. 808). Flowers with the parts mostly in threes or fours, never in fives. Embryo with a single seed-leaf (cotyledon). First-formed leaves alternate; radicle not branching, but throwing out adventitious roots.

Division I. PETALOIDEÆ (p. 805 to p. 952).

Flowers hermaphrodite, rarely unisexual. Perianth rarely absent, usually in two series; the inner series or corolla usually petal-like; the outer series or calyx often also petal-like.

Series 1.—HYPOGYNAE.—Ovary superior, carpels more or less free and distinct from each other, or completely united.

Natural Orders with these Characters.—NALADACEÆ (p. 805), ALISMACEÆ (p. 805), COMMELINACEÆ (p. 807) LILIACEÆ (p. 808), JUNCACEÆ (p. 882), PONTEDERIACEÆ (p. 882).

Series 2.—EPIGYNAE.—Ovary inferior. Flowers regular, irregular, or zygomorphic. Stamens in threes or sixes, sometimes reduced to one only, and sometimes in waxy pollen masses.

Natural Orders with these Characters.—HYDROCHARIDEÆ (p. 883), DIOSCOREACEÆ (p. 884), SCITAMINEÆ (p. 884), HÆMODORACEÆ (p. 889), ORCHIDEÆ (p. 890), AMARYLLIDEÆ (p. 893), IRIDEÆ (p. 916).

Division II. SPADICIFLORÆ (p. 952 to p. 956).

Flowers small, usually on a spadix, sometimes solitary, frequently unisexual, but sometimes dioecious. Perianth often wanting, never petal-like.

Natural Orders with these Characters.—*TYPHACEÆ* (p. 952), *AROIDEÆ* (p. 953), *PALMEÆ* (p. 955).

Division III. *GLUMIFLORÆ* (p. 956 to p. 972).

Flowers hermaphrodite or unisexual, and then mostly monœcious, usually in heads or spikelets invested by imbricate bracts. Perianth absent or scaly. Ovary superior, 1- or more celled.

Natural Orders with these Characters.—*GRAMINEÆ* (p. 956), *CYPERACEÆ* (p. 971).

SUMMARY OF THE ABOVE

Sub-Kingdom I. FLOWERING PLANTS (p. 131 to p. 1008).

Class I. ANGIOSPERMS (p. 131 to p. 972).

Sub-Class I. Dicotyledons.

Division (i). Polypetalæ (p. 131 to p. 477).

Series (a) *Thalamifloræ* (p. 131 to p. 284).

„ (b) *Discifloræ* (p. 284 to p. 322).

„ (c) *Calycifloræ* (p. 322 to p. 477).

Division (ii). Gamopetalæ (p. 477 to p. 759).

Series (a) *Epigynæ* (p. 477 to p. 571).

„ (b) *Hypogynæ* (p. 571 to p. 759).

Division (iii). *INCOMPLETEÆ* (p. 759 to p. 805).

Sub-Class II. Monocotyledons.

Division (i). *Petaloideæ* (p. 805 to p. 952).

Series (a) *Hypogynæ* (p. 805 to p. 883).

„ (b) *Epigynæ* (p. 883 to p. 952).

Division (ii). *Spadicifloræ* (p. 952 to p. 956).

Division (iii). *Glumifloræ* (p. 956 to p. 972).

Class II. *GYMNOSPERMS* (p. 972 to p. 1008), including *GNETACEÆ* (p. 972), and *CONIFERÆ* (p. 972).

Sub-Kingdom II. NON-FLOWERING PLANTS (p. 1008 to p. 1024).

FERNS (p. 1008), *HORSETAILS* (p. 1023), *CLUBMOSSES* (p. 1024).

How to use the 'Key.'—It may perhaps be as well to give an idea as to the way in which the 'Key' is to be used for finding out the order, genus, and species to which any particular plant may belong. First of all, the plant should be carefully examined in regard to the roots, stem, leaves, flowers &c., noting size, shape, colour &c., and the 'Key' should then be used in the following sequence, as shown in the summary

above. 1. Sub-Kingdom. 2. Class. 3. Sub-Class. 4. Division. 5. Series. 6. Cohort or subordinate group of each series. 7. Natural Order. 8. Genus. 9. Species.

For the sake of example, let the reader assume that he has a Wallflower but does not know that it is a Wallflower. He is then to proceed as follows to find out what it is from the 'Key.'

1. He consults the two sub-divisions of the Vegetable Kingdom ((1) 'Flowering' and (2) 'Non-Flowering' Plants) and decides that it belongs to the flowering one, as it has flowers and is therefore what botanists call a 'Phanerogam.'

2. He then refers to the two 'Classes' of Flowering Plants (Angiosperms and Gymnosperms), and having discovered that the flowers have (i) a distinct perianth, and (ii) ovules (young seeds) enclosed in carpels or pods, the plant is regarded as belonging to the group called 'Angiosperms,' or plants with seeds hidden or concealed within an ovary or fruit.

3. The two sub-classes of Angiosperms, *i.e.* 'Dicotyledons' and 'Monocotyledons,' are next referred to, and as it has (i) net-veined leaves, (ii) bark or rind to the stem, and (iii) the parts of the flower arranged in fours or fives, he places it down as a 'Dicotyledon.'

4. There are three divisions of Dicotyledons: namely, *Polypetalæ* (p. 122), *Gamopetalæ* (p. 125), and *Incompletæ* or *Monochlamydeæ* (p. 126); and it is found that the Wallflower belongs to 'Polypetalæ,' (i) because the flowers have 'both calyx and corolla,' and (ii) because the petals are 'free or distinct from each other.'

5. Polypetalæ is divided into three groups or 'series'—Thalamifloræ (p. 122), Discifloræ (p. 123), Calycifloræ (p. 124), and it will be found that the Wallflower belongs to Thalamifloræ, because (i) the stamens are hypogynous and are inserted on a torus, thalamus, or receptacle, and not on the calyx tube as in Calycifloræ, and (ii) the flowers are not in fives as in most of the Discifloræ.

6. When a series is divided into 'cohorts' or sections the characters of each of these are examined in the same way. The Wallflower evidently does not belong to the cohort 'Ranales,' (i) because the carpels are not free, and (ii) because the stamens are not numerous. But owing to the ovary, or seed pod, being 1-celled, and containing many ovules or seeds, it may be safely assumed to belong to the 'Parietales' group, which has such characters.

7. Under this group there are eight distinct natural orders mentioned. The point now is to find out to which one of them the Wallflower belongs. They are taken in rotation, and the characters of each will be found at the page given in brackets. It is unnecessary to

detail the reasoning process with each order, but the reader may take it for granted or reason it out as above that the Wallflower belongs to the natural order 'Cruciferae,' because it agrees in the main with all the essential characters of the order as set forth at p. 201, and it cannot be made to fit into any other order.

8. Having found the order, the genus or surname of the plant has next to be found. The genera in each Order follow in natural (not alphabetical) order, and the reader will find that his Wallflower will not fit into the first genus, 'Matthioli' or Stock (p. 201), nor into the second, 'Parrya' (p. 203), but it agrees in almost every detail with the characters of the third genus, 'Cheiranthus' (p. 204). It is therefore placed under that genus and bears its name.

9. The last step in the identification of the plant is to discover what species it is. As there are generally only a few of these in each genus, they have been described in alphabetical order, for the sake of convenience. The characters of each species have been given in sufficient detail to enable the reader to decide for himself which specific (or as it were christian) name he is to apply to the plant. He may regard species in the same light as brothers and sisters, differing from each other in details, but all having the same family or surname.

10. *Varieties*.—Besides the above nine steps to be followed in tracing or running down any plant, it may be added that there are often many 'varieties' or forms of one species (see, for example, *Clematis heracleæfolia*, p. 133). These varieties usually agree in almost every detail with the species, but often have flowers of a different shade of colour, or the leaves may be broader or narrower, hairy or smooth, and so on. Where such characters are constant, a varietal name, often describing the peculiarity, such as *alba*, *rosea*, *purpurea*, *tomentosa*, is sometimes given.

11. *Florists' Varieties*.—What are known as florists' varieties, however, are quite distinct from natural varieties. The custom now is to give popular fancy names to florists' varieties, and they represent often only the slightest variations in colour shades, which may differ with good or bad cultivation, shadow or sunshine &c., and can in no way be kept constant if the plants are increased from seeds.

It therefore matters little what name is given to florists' varieties of such plants as *Clematis*, *Pæonia*, *Carnation*, *Pink*, *Polyanthus*, *Primrose*, *Violet*, *Pansy*, *Phlox*, *Pentstemon*, *Hollyhock*, *Rose*, *Dahlia*, *Chrysanthemum*, *Gladiolus*, and many others, although for the sake of convenience one must use them when they represent really fine garden plants.

THE
HARDY FLOWER GARDEN

DESCRIPTION, CULTURE, AND PROPAGATION OF THE MOST
DESIRABLE HERBACEOUS AND ALPINE FLOWERS, ORNAMENTAL
AND FLOWERING TREES AND SHRUBS, BAMBOOS, FERNS, &c.,
SUITABLE FOR THE OPEN AIR IN THE BRITISH ISLANDS.

Division I. *POLYPETALOUS DICOTYLEDONS*
Series I.—*THALAMIFLORÆ* (see p. 122).

I. *RANUNCULACEÆ*—Crowfoot or Buttercup Order

Chiefly herbaceous plants, rarely shrubs, with alternate or opposite (as in *Clematis*) and generally much-divided leaves, the stalks of which are dilated at the base, forming a sheath half clasping the stem. Flowers regular or irregular, with 3–6 hypogynous deciduous sepals, usually imbricate in bud. Petals 3–15, hypogynous, in one or more rows, sometimes assuming very remarkable forms, as in Larkspur (*Delphinium*), Columbine (*Aquilegia*), and Monkshood (*Aconitum*). Stamens usually numerous, hypogynous. Carpels numerous, one-celled, free, or occasionally united into a many-celled pistil. Fruit either consists of dry, indehiscent achenes, as in Buttercup; or berries, as in Baneberry; or follicles, as in the Pæony.

The order contains about 1,000 known species, chiefly natives of damp, cold climates. A few are found in the tropics, but at very high elevations.

CLEMATIS (TRAVELLER'S JOY; THE VIRGIN'S BOWER).—A genus of shrubs which creep or climb by their leaf-stalks, and have opposite compound leaves, without stipules. Calyx consists of 4 petal-like sepals (garden forms have more) usually valvate. There is no corolla, and the fruit is a head of sessile or stalked achenes, with long, generally feathered awns or styles, which give the plants a beautiful appearance even in winter.

Culture and Propagation.—Clematises like a rich loamy soil with a certain amount of chalk or lime, and are benefited

by a mulching of good rotten manure in autumn. The plants are very ornamental trained over walls, trellises, arbours, &c. They may be propagated by sowing the seeds in spring in light sandy soil, in gentle heat; or in cold frames as soon as ripe, afterwards pricking the seedlings out and giving more space for a sturdy development. Planting out may take place in spring or early in autumn. Clematises may also be increased by layers outside put in at any time, but care must be taken that they are not separated from the parent plants until well rooted.

Cuttings may also be made from the young shoots, cut almost to every eye and placed in a hotbed in sandy soil early in spring. The garden hybrids are generally grafted in spring on the roots of such species as *C. Vitalba*, *C. Viticella* and *C. Flammula*, but unsatisfactory results often follow owing to an imperfect union between stock and scion, and also perhaps because growth in spring begins, or tries to begin, in one before the other. If the scion, for example, would naturally start into growth on its own roots a week or so in advance of the stock, it is easy to see that trouble would arise from this cause; and the same with the stock starting into growth before the scion was naturally ready to absorb the sap. Increase by cuttings and layers is now more general in many places, but many kinds also admit of being divided at the root in spring or autumn in favourable weather.

C. æthusifolia.—A graceful climber, 4–6 ft. high, from N. China, with small twice or thrice pinnatisect leaves with narrow linear lobes. The bell-shaped or tubular flowers are half an inch or more long, yellowish-white, and are produced in great profusion in summer. The variety *latisecta* is distinguished from the type by its larger leaf segments.

Culture &c. as above.

C. alpina (*Atragene alpina*; *A. austriaca*; *A. sibirica*).—A pretty climber from the mountains of Europe. The biternate leaves have ovate-lance-shaped, pointed, serrate leaflets. Flowers in May vary from blue to white; petals 10–12, linear at the base, dilated at the apex. There is a white-flowered variety named *alba*.

Culture &c. as above.

C. apiifolia.—A vigorous species about 10 ft. high, native of China and Japan. It has ternate leaves, and dull white flowers, 3–4 in. across, in August and September.

C. brevicaudata (or *C. Pieroti*), with pinnate or twice ternate leaves, and small white flowers, is very near this.

Culture &c. as above.

C. aromatica (*C. cærulea odorata*).—A slender sub-shrubby species, 4–6 ft. high, probably of hybrid origin between *C. integrifolia* and *C. recta*. The leaves have five shortly stalked or almost sessile lobes more or less ovate-oblong in shape. The sweet-scented solitary flowers appear

in summer and are about 2 in. across and of a deep violet-blue.

Culture &c. as above.

C. cærulea (*C. azurea grandiflora*).—A Japanese species with spreading hairy ternate leaves, having ovate-acute entire leaflets. The large violet-coloured flowers with deep purple stamens are produced about June and July.

Many garden forms have originated from this species.

Culture &c. as above.

C. calycina (*C. balearica*, A. Rich).—This species—a native of Corsica and Minorca—is hardy only in the south of England and the milder parts of the British Isles. The ternate leaves have 3-lobed stalked and deeply toothed leaflets, which in winter assume a fine bronzy tint. The greenish-yellow bell-shaped flowers are about 2 in. across, and heavily spotted with reddish-purple. They are produced from January to April in clusters of four or five and look very attractive at that season.

Culture and Propagation.—This species should be sheltered by growing on a south wall. It likes a rich loamy soil, and is best left to ramble about at will, as it dislikes the use of the knife. The foliage is evergreen, and during the autumn and winter months may be used for room decoration with flowers, owing to its rather attractive tints.

C. campaniflora.—A Portuguese climber, 12–18 ft. high, having biternately cut leaves, subdivided into about twenty-four entire or 3-lobed leaflets. The pale violet or white bell-shaped flowers are about one inch across, and are freely produced in June and July.

Culture &c. as above.

C. cirrhosa (*C. balearica*, Pers.).—An evergreen climber 8–10 ft. high. Native of Spain, Algiers, and the mountains of N. Africa. Leaves ovate, somewhat heart-shaped, toothed. Flowers dull white or cream-coloured, about 1½ in. across, downy outside, smooth within, produced in drooping clusters about March and April.

Culture &c. as above.

C. coccinea (*C. texensis*).—A beautiful species from Texas, with stems 6–10 ft. high, which in this country usually die down in winter. The flowers vary in colour from crimson to scarlet, and are swollen at the base, the tips of the 4 leathery sepals being recurved. They

appear during the early summer months and at once attract attention by their vivid colour. This species has been used in the production of various hybrids. The variety *major* has larger flowers than the type.

Of late years several beautiful hybrids between this and some of the leading hardy kinds have been raised by Messrs. Jackman, of Woking, the most notable being 'Countess of Onslow,' 'Duchess of York,' and 'Duchess of Albany.' All were figured in the 'Garden' for October 16, 1897.

Culture &c. as above.

C. connata.—A beautiful Himalayan climber with woody stems and coarsely toothed leaflets 3-5 in. long, and sometimes more or less 3-lobed. Flowers in autumn, bell-shaped, clear yellow, recurved at the tips.

Culture &c. as above.

C. crispa (*C. cylindrica*; *C. Simsi*).—A hardy evergreen from N. America, 3-4 ft. high, with purplish stems. Leaves entire, 3-lobed or ternate, acute. The nodding pale lilac, white, or purple fragrant flowers appear from June until the autumn. There seems to be great variation in the leaves and colour of the flowers of this species.

Culture &c. as above.

C. Douglasi.—Although discovered many years ago on the Rocky Mountains, this species is not yet well known in British gardens. The flowers are about an inch long, bell-shaped, and recurved at the tips, deep purple within, paler outside. They are produced in summer.

Culture &c. as above.

C. Flammula.—This native of Southern Europe is one of the oldest Clematides in cultivation, and at the same time one of the most vigorous and free-flowering of climbers. Leaves pinnate, smooth, with roundish, oval, oblong, or linear entire or 3-lobed deep green leaflets, which remain on the plants well into the winter. The creamy white, fragrant flowers are less than an inch across, and appear in late summer and autumn, giving place to white and feathery fruits.

Culture &c. as above.

C. florida.—A Japanese species 9-12 ft. high, with ternately decompound leaves, and ovate-acute entire leaflets. When fully open the creamy white solitary flowers, consisting of 6 or 8 oval lanceolate sepals, are from 2-4 in. across with purple stamens in the centre. They appear from April to September.

There is a well-known and beautiful form with double flowers.

Culture &c. as above.

C. Fortunei.—A splendid species, also from Japan, with leathery trifoliolate leaves, and roundish heart-shaped leaflets. The white fragrant flowers, about an inch across, consist of numerous oblong-lanceolate stalked segments, and appear during the summer months.

Culture &c. as above.

C. Fremonti.—A dwarf species 1-2 ft. high, from North America. The rarely branched stems bear numerous unstalked leathery leaves, 3-4 in. long, and drooping purple flowers recurved at the tips produced during the summer. The tails or awns of the fruits are downy when young.

Culture &c. as above.

C. fusca.—A somewhat shrubby species from N. Asia with prostrate rather than climbing stems, 6-8 ft. long. The reddish-brown bell-shaped flowers appear in summer and are covered with a short thick brownish wool. The hairy fruits form a globular head about one inch in diameter.

Culture &c. as above.

C. Hendersoni (*C. eriostemon*).—This is supposed to be a hybrid between *C. Viticella* and *C. integrifolia*, and originated at Mr. Henderson's nursery, St. John's Wood, in 1835. It reaches a height of 8-10 ft. and produces from June to September deep blue, faintly perfumed flowers over two inches across.

Culture &c. as above.

C. heracleæfolia (*C. tubulosa*).—*Hyacinth Clematis*.—A dwarf, sturdy species from N. China, with more or less trailing stems, large lobed leaves, and short stalked corymbs of purplish-blue tubular flowers, like those of a Hyacinth, produced during the summer and early autumn months.

The variety *davidiana* is often regarded as a species. It has trailing stems 4-5 ft. long, and large ovate leaflets often about 6 in. long. Flowers tubular, bright lavender-blue, about $\frac{3}{4}$ in. long, the tips of the petals reflexed.

The variety *Hookeri* has large pinnately 3-foliolate leaves with elliptic acute toothed leaflets, and tubular lilac flowers.

Culture &c. as above. The plants are readily increased by division of the roots in spring.

C. indivisa.—A charming New Zealand species growing several feet high, having dull green or purplish stems and ternate leaves, the latter being composed of 3 oblong ovate leathery deep green smooth leaflets $2\frac{1}{2}$ –3 in. long. The pure white starry flowers, about 3 in. across, and consisting of 6–8 oblong sepals surrounding a cluster of greenish or yellowish-white stamens, appear out of doors in April and May, but in February if the plants are grown in greenhouses. They are borne in loose panicles, sometimes as many as 20 in one truss. The variety *lobata* has flowers exactly like those of the type, but it is readily recognised by means of its more or less lobed or sinuated leaflets.

Culture and Propagation.—Unfortunately this fine species is hardy only in the mildest parts of the south and west, but in other parts of the kingdom it is well worth growing in a cool greenhouse for the sake of its attractive flowers. It likes a rich sandy loam and warm situations out of doors, and is usually increased by grafting upon stocks of the Common Traveller's Joy (*C. Vitalba*). Cuttings of the half-ripened shoots, however, will root readily in early summer if placed in sandy soil in gentle bottom heat in a hotbed or greenhouse. Amateurs will probably find it more convenient to obtain established plants from a nurseryman. Pruning, if necessary, is best done immediately flowering has ceased, and not while new growths are being made.

C. integrifolia.—A European species with erect stems 2–3 ft. high. Leaves unstalked, 2–4 in. long, entire, ovate-lanceolate. The drooping blue flowers are borne singly from June to August near the top of the stems in the axils of the united and cup-shaped leaves.

The variety *Durandi* has 5-nerved leaves 4–5 in. long, with a purplish downy margin, and purple beneath. Flowers deep violet-purple, each sepal with a prominent deeper coloured keel behind. Stamens in a thick cylindric silky cushion, white and yellow.

Culture &c. as above.

C. lanuginosa.—A fine Chinese species 5–6 ft. high. Leaves usually simple, broadly heart-shaped, acute, smooth above, with a greyish wool on the under surface. The solitary flowers appear early in summer, lasting till autumn, and

are 6–7 in. across, with 6 or 8 spreading and overlapping sepals of a pale lavender, pure white or deep rich purple colour.

The variety *pallida* has flowers 9–10 in. across.

C. lanuginosa is the parent of many of the most beautiful garden hybrids described below.

Culture &c. as above.

C. ligusticifolia.—A species with stems about 30 ft. long, from North America. Leaves composed of 5 leaflets, each $1\frac{1}{2}$ –3 in. long, 3-lobed or very coarsely toothed. Flowers white, about $\frac{3}{4}$ in. across, are produced in summer, the pistillate or female flowers being on one plant, and the staminate or male on another.

Culture &c. as above.

C. montana (*C. anemonæflora*).—This beautiful and well-known species is a native of the Himalayas. Its stems will cover walls to a height of 20 ft. or more, and are furnished with smooth ternate leaves, with oblong toothed and pointed leaflets. During April and May the large white flowers are produced in great profusion, either singly or several together, and almost cover the foliage with a sheet of white.

Culture &c. as above. This species will flourish under almost any circumstances and in any soil.

C. ochroleuca.—A native of the Eastern United States, with stems 1–2 ft. high, and entire ovate leaves, the younger ones being silky beneath. Flowers in summer, solitary, cream-coloured within, yellowish outside.

Culture &c. as above.

C. orientalis.—A native of India and W. Asia, requiring some protection in this country during severe winters, especially in the less favoured parts. The stems climb from 12 to 30 ft. Leaves pinnate with smooth wedge-shaped leaflets having pointed lobes. Flowers in August and September, greenish-yellow, sweet-scented, tinged with russet, and borne in great abundance. The fruits have elegant silky tails. This species is also known as *C. graveolens*, a name having reference to the rather heavy odour of the blossoms.

Culture &c. as above. Easily increased by cuttings or seeds.

C. Pallasi.—A pretty plant 3–4 ft. high with trailing stems, pinnate leaves

and shortly stalked, ovate, lance-shaped, acute, leathery leaflets 1-1½ in. long, with sunken veins. Flowers in June, white with greenish-yellow stamens, and oblong spoon-shaped sepals.

Culture &c. as above.

C. paniculata. — A Japanese species the stems of which attain a length of about 30 ft. Leaves pinnate with entire oval heart-shaped acute leaflets. From July to September the dullish white flowers, which resemble those of *C. Flammula*, and have a Hawthorn- or Daphne-like fragrance, are produced in many-flowered panicles.

Culture and Propagation.—This plant does best trained against a sunny wall, or for covering old tree stumps, pillars &c., in warm southern parts. The stems may be cut down to within a foot or so of the ground in winter to keep the plant within bounds.

C. patens.—Also a native of Japan, 6-10 ft. high with leaves composed of 3-5 segments smaller and narrower than in *C. lanuginosa* to which it is akin. Flowers in May and June, with 6-8 delicate mauve sepals.

Many garden varieties, some of which are mentioned below, have larger flowers with white, deep blue, or violet sepals.

Culture &c. as above.

C. Pitcheri (*C. coloradensis*).—A pretty and distinct plant 9-12 ft. high, native of Colorado and Western America. Its leaves consist of 3-9 ovate or heart-shaped, entire or 3-lobed leaflets, the uppermost leaves being often simple. The dull purplish, bell-shaped flowers, each about 1 in. long and ¾ in. wide at the swollen base, appear during July and August, and have narrow recurved sepals, the tips of which are often yellow. The reddish-purple fruits have thread-like tails slightly silky.

The variety *lasiostylis* is distinguished by the recurved sepals being tipped with deep purple-blue and by the deeper coloured and more hairy fruits; and *Sargentii* is a small-flowered form of the type.

Culture &c. as above.

C. recta (*C. erecta*).—A species with erect herbaceous stems 2-3 ft. high, native of Southern and Eastern Europe. The pinnate leaves have entire, ovate, pointed,

stalked leaflets. Flowers from June to August, numerous, in dense corymbs, white and sweetly scented, each about an inch across. The variety *flore pleno* is not often seen. It differs in having double flowers in rather denser clusters.

Culture &c. as above. This species may be increased by dividing the roots.

C. reticulata.—A climber from the S. United States with leathery prominently net-veined leaves; the upper ones simple elliptic; lower ones pinnate with 7-9 variable leaflets. Flowers in September, dull green outside, purple within, solitary, drooping on long stalks. Sepals united, recurved at the tips, and thick and fleshy in texture.

Culture &c. as above.

C. rhodochlora.—A garden variety with simple broadly oval, or somewhat heart-shaped shortly stalked leaves. Flowers about 2 in. across, with 2 small wine-red sepals and 2 large green ones.

Culture &c. as above.

C. Robertsiana.—This species has only recently been discovered 10,000-11,000 ft. up on the mountains of Afghanistan, and is probably not yet in cultivation. Flowers solitary, 3-5 in. across, pale lemon-yellow, closely resembling *C. alpina* in shape.

Culture &c. as above

C. Stanleyi.—A remarkable species 2-3 ft. high, native of S. Africa. It is shrubby rather than climbing in habit, and the stems die down to the ground every winter, new ones sprouting up in spring. The leaves are twice pinnate with variously cut lobes, and are mostly covered with soft silky white hairs, although a few leaves are greenish but hairy. The flowers are produced during the summer months in the axils of the leaves, and vary from 2 to 3 in. across, the sepals being at first cup-shaped, but afterwards spreading out flat. They vary in colour from deep violet or puce to rose-purple, and almost white, and are in strong contrast to the large bunch of bright yellow stamens in the centre. When in fruit the plants present an elegant appearance, owing to the long silvery-white tails resembling miniature ostrich feathers.

Culture and Propagation.—In mild winters this species is fairly hardy as far north as the Thames Valley, but it is

safer to protect the roots with a layer of dry leaves, litter, bracken &c. in the event of severe weather. Seeds are freely produced and may be sown in cold frames as soon as ripe, although they may not sprout freely until the following spring. The seedlings must be pricked out and grown on until the following spring, so that strong sturdy plants will be ready for planting out. Established clumps may be carefully divided at the roots.

C. Stans.—A striking Japanese species with herbaceous stems 4–5 ft. high and dark green downy leaves, with roundish toothed leaflets, more or less 3-lobed. Flowers in September and October in terminal panicles or clusters in the axils of the leaves, each about $\frac{3}{4}$ in. long, pale blue, more or less bell-shaped, and Hyacinth-like.

Culture &c. as above.

C. verticillaris (*Atragene americana*). A native of N. America with stems 10 ft. or more in length. Leaves whorled, in fours, with stalked heart- or lance-shaped pointed leaflets, somewhat lobed or serrated. Flowers in May, 2–3 in. across, purplish-blue, with acute sepals.

Culture &c. as above.

C. Viorna (*Leather Flower*).—This N. American species attains a height of 10 to 12 ft. and is not a particularly vigorous grower. The smooth pinnate leaves have entire 3-lobed or ternate leaflets, ovate-acute in shape. About June the drooping balloon-shaped flowers appear, having thick leathery connivent sepals of a dull reddish-purple, and reflexed at the tips.

Closely related to this species is *C. Addisoni*, a native of the Alleghany mountains. It has dark violet-purple sepals, with reflexed yellow tips.

Culture &c. as above.

C. virginiana.—This is the common Virgin's Bower of the United States and Canada. Its stems reach a length of 15 to 20 ft., and bear ternate leaves with heart-shaped, acute, largely toothed or lobed leaflets. The small white fragrant flowers appear from June to August, and like *C. ligusticifolia* the male and female flowers are borne on separate plants.

Culture &c. as above.

C. Vitalba (*White Vine*; *Old Man's Beard*; *Traveller's Joy*, &c.).—This is the only Clematis really indigenous to

England, but does not appear to be a native of Scotland or Ireland. It climbs luxuriantly in hedges and thickets, and is most common on chalky soils. The pinnate leaves have ovate, heart-shaped, entire toothed or lobed leaflets. The greenish-white scented flowers are about an inch across, and are produced from July to September. The fruits have a white feathery tail an inch or so in length, and these give the plants a very attractive appearance late in the year, and during the winter months.

In the Duke of Rutland's garden at Belvoir Castle there is a specimen 20 ft. high and 30 ft. in diameter.

Culture &c. as above.

C. Viticella (*Vine Bower*).—An elegant twiner 8–12 ft. high, and native of S. Europe and Western Asia. The leaves are entire or ternately decomposed with entire lobes. The drooping blue, purple, or rose-coloured flowers, each about 2 in. across, are borne in summer. There are now many varieties of this species with many shades of colour, and most of them are superior to the type. The form called *magnifica* has purple flowers about $4\frac{1}{2}$ in. across.

Culture &c. as above.

HYBRID CLEMATIS.—By means of fertilising the carpels of one species with the pollen from another, gardeners have succeeded in raising a vast number of hybrids or cross-breeds, many of them being of the greatest value for the flower garden, and superior to any of the species found in a state of nature. (See Hybridisation, p. 37.)

It is, however, not only impossible but quite unnecessary to give a long list of the various hybrids here, as new names are continually being added, often without any justification, whenever the slightest change of colour is noticed.

Special mention must be made of the beautiful *Clematis Jackmanni* and its many forms. This fine hybrid was raised by Mr. George Jackman of Woking, and first flowered about 1862. It is one of the earliest and best, and its large deep violet-purple flowers with 4–6 sepals are produced during the summer and autumn. The two species concerned in its production were *C. Viticella* and *C. lanuginosa*, natives of widely different parts of the Old World. The species chiefly concerned with the other garden varieties are

given below in sections, and it will be seen that only a few have yet been utilised by the hybridiser out of the many kinds described above.

The following is a list of the best kinds for the flower garden. They are arranged in the botanical sections to which they belong, and the usual period of flowering is given, so that a succession of kinds may be arranged. The culture and propagation are as described above under the genus, p. 131.

'FLORIDA' SECTION

The following produce large handsome double flowers in summer from the old or ripened wood. Care must therefore be taken, when pruning or thinning, not to cut the ripe wood away.

Belle of Woking, beautiful silver-grey, June.

Countess of Lovelace, bright bluish-lilac, very fine, June.

Duchess of Edinburgh, pure white, deliciously scented, June and July.

John Gould Veitch, lavender.

Lucie Lemoine, white, with the centre in the form of a rosette.

'JACKMANNI' SECTION

These are all summer and autumn bloomers, flowers mostly large, produced in masses on the current year's shoots.

Alexandra, pale reddish-violet, very free.

Gypsy Queen, dark velvety purple, attractive.

Jackmanni, intense violet-purple, a universal favourite.

Jackmanni alba, a tinted white var., very beautiful.

Jackmanni 'Snow White', pure white, free.

Jackmanni superba, very dark violet-purple, larger and of deeper colour than *Jackmanni*, very profuse bloomer.

Madame Ed. André, a free and distinct variety with velvety-red flowers.

Madame Grange, flowers crimson-violet, with red bar in centre, a rich colour, sepals prettily crimped at the edges.

Prince of Wales, deep purple.

Star of India, reddish-violet, with purple tinge and red bars.

'LANUGINOSA' SECTION

These flower summer and autumn, producing their large flowers in succession on short lateral shoots.

Alba Magna, a very large white-flowered variety of free growth.

Beauty of Worcester, double and single flowers of a lovely bluish-violet, with white stamens.

Blue Gem, pale blue.

Excelsior, rich deep mauve.

Fairy Queen, pale flesh with pink bar.

Henry, large creamy white, finely formed, one of the best white autumn-flowering Clematises.

La France, deep violet-purple, dark anthers, large and vigorous.

Lady Caroline Neville, delicate bluish-white with mauve bars, large and finely formed.

Marie Lefebvre, a fine mauve variety with single flowers.

Mme. Van Houtte, white suffused mauve, free-flowering and a strong grower.

Mrs. Hope, silvery-mauve.

Nivea, large white, fine.

Otto Fræbel, greyish-white.

Princess of Wales, deep bluish-mauve, with satiny surface, very fine.

Purpurea elegans, deep purple.

'PATENS' SECTION

These produce their large flowers in spring and summer, on the old ripened wood, a fact to be borne in mind when thinning out.

Lady Londesborough, bluish-lilac, with pale purple bar.

Miss Bateman, white, chocolate-red anthers.

Mrs. George Jackman, satiny white with a creamy bar, flowers large and produced in profusion spring and autumn.

'VITICELLA' SECTION

These varieties flower during the summer and autumn in profuse masses.

hybrida Sieboldii, lavender.

Lady Bovill, flowers greyish-blue, cup-shaped, fine.

rubra grandiflora, bright claret-red, profuse bloomer.

THALICTRUM (MEADOW RUE).—

A genus embracing about fifty species of hardy herbs with perennial stems, nearly all natives of the North temperate and frigid regions. The leaves are ternately decomposed, and usually elegant in appearance; when present on the stems, alternate. Flowers green, yellow, purple, or white, often polygamous, borne in panicles or racemes, usually small, with the stamens conspicuously protruding.

Involute and petals absent. Sepals 4-5, petal-like. Carpels numerous. Fruit an achene, often stalked and compressed.

Culture and Propagation.—The Meadow Rue will grow well in any ordinary garden soil, and are easily multiplied by dividing the rootstocks in autumn or spring.

When grown in masses or clumps in the border or rock garden, they lend a light and feathery grace to the surroundings. For cutting purposes the foliage and flowers are very useful when mixed with larger and more showy blossoms. Seeds may be sown out of doors or in cold frames as soon as ripe, or in spring, afterwards pricking the seedlings out in mild, showery weather.

T. alpinum.—This is a native of the British Isles, although somewhat rare in Ireland in a wild state. It will thrive in marshy or boggy places and requires peaty soil. The foliage is glaucous beneath, and the purplish flowers with drooping stamens appear in July and August.

Culture &c. as above.

T. anemonoides (*Rue Anemone*).—This N. American species has a stem about 6 in. high arising from a cluster of thickened tuberous roots. The white flowers appear in April and May, and have yellowish stamens. The leaves are 2-3-ternate with roundish somewhat 3-lobed leaflets on long stalks. A useful rock plant. There is a double variety with smaller flowers.

Culture &c. as above. This species is often called *Anemone thalictroides*. It is as a rule best raised from seeds, owing to the fact that if established clumps are divided they often take a long time to recover themselves. A partially shaded situation in the rockery, such as under a jutting boulder of rock, and a deep moist peaty soil suit it admirably.

T. angustifolium.—A pretty species 3-4 ft. high, native of W. Europe, having masses of light and graceful, deeply cut foliage. The clear greenish-yellow flowers are produced in feathery clusters in June and July, and give the whole plant a fine effect.

Culture &c. as above.

T. aquilegifolium (*Feathered or Tufted Columbine*).—A native of Europe and Asia with purple mealy pipe-like stems 1-3 ft. high. Leaves like those of the

Columbine, thrice pinnate with rounded, smooth deeply toothed leaflets. Flowers in early summer. Sepals white, fleeting; stamens usually purple, sometimes white.

The variety *atropurpureum* has dark purple stamens and stems; the variety *formosum* dark purple stamens, dilated at the apex; and the variety *roseum* has rose-coloured sepals.

Culture &c. as above.

T. Chelidoni.—A pretty little species about 6 in. high, native of Thibet. The twice ternate leaves are divided into downy and roundish 3-lobed and toothed leaflets each $\frac{1}{2}$ - $\frac{3}{4}$ in. across, and the lilac-purple flowers with a bunch of yellow stamens in the centre droop from thread-like stalks in August, like those of *T. Delavayi*.

Culture &c. as above. This is a pretty rock plant, but to be effective should be grown in bold masses.

T. Delavayi.—A charming Chinese species 2-4 ft. high, with pinnate leaves ternately divided into roundish and somewhat 3-lobed and toothed leaflets. The flowers appear during the summer months gracefully drooping or nodding from the ends of slender thread-like stalks. They are lilac-purple in colour with a large bunch of yellowish stamens in the middle, and in conjunction with the elegantly cut foliage look extremely handsome.

Culture &c. as above.

T. flavum (*False Rhubarb; Fen Rue*).—A native of the British Islands, growing in wet places, and worthy of a place among marsh or bog plants in the garden. The stout stems arise 2-4 ft. high from a yellow creeping rootstock, and bear ternately 2-3-pinnate leaves, with 3-lobed leaflets 1-1 $\frac{1}{2}$ in. long. Flowers pale yellow, anthers bright yellow, produced in July and August.

Culture &c. as above.

T. foetidum (*Fetid Meadow Rue*).—A native of Europe and Asia, about 1 ft. high. Leaves decomposed clothed with a clammy pubescence, 2-3-pinnate, with roundish heart-shaped leaflets, 3-5-lobed at apex. Flowers small, nodding, produced in early summer in an erect, spreading panicle. Sepals reddish outside; anthers yellow.

Culture &c. as above.

T. glaucum.—A South European species, with round, erect, striped and mealy stems 2-5 ft. high. The leaflets are

ovate, rounded, 3-lobed, the lobes deeply toothed. In June and July the flowers, having four or five yellow sepals, are borne on erect, compound panicles.

Culture &c. as above.

T. minus (*Maidenhair Meadow Rue*).

A native of the British Isles, growing in dry places. The stems vary from 6 in. to 4 ft. high, stout, rigid, often zig-zag, striped more or less throughout, and usually furrowed when dry. Leaves Fern-like, cut into numerous small smooth roundish glaucous leaflets, toothed at the apex. Flowers in summer, small, and drooping in a loose panicle. Sepals yellowish-green or pale purple with white edges.

Owing to the beautiful frond-like foliage of this plant, it is suitable for rockeries, borders, and even as a pot-plant. For mixing with cut flowers in vases, the foliage is very ornamental, and lasts much longer than Maidenhair Fern.

Culture &c. as above.

T. petaloideum.—A Dahurian species with round almost naked stems about 18 in. high. Leaves ternately cut, with smooth, ovate, obtuse, entire or 3-lobed leaflets. Flowers produced in corymbs in June and July, with white, nearly round sepals, flesh-coloured filaments, and yellow anthers.

Culture &c. as above.

T. rhynchocarpum.—A very remarkable and handsome species, about 3 ft. high, native of the Transvaal. The foliage resembles some of the finer forms of the Maidenhair Fern. The flowers are borne in large panicles during the summer months, and are succeeded by the fruits, which are borne on long stalks and present a novel and attractive appearance.

Culture and Propagation.—This species likes a warm, moist, and shaded spot in the rockery, and will not flourish in strong sunshine. The soil must be well drained, and a little protection in winter may be necessary. Increased by seeds and division.

T. tuberosum.—A Spanish species about 12 in. high, with 2-3-pinnate crowded leaves, and smooth roundish 3-lobed leaflets. Flowers borne in loose corymbs in June, and having 5 white oval, blunt sepals.

Culture &c. as above.

ANEMONE (WIND FLOWER).—The generic name is derived from *anemos*, the wind, in allusion to the light and feathery seeds of some species which are easily blown about by the wind.

A genus of about 70 species of ornamental hardy perennials, with radical leaves much cut or lobed. There is an involucre of 3 cut leaflets some distance from the flower. Sepals 4-20 petal-like. Petals absent, or consist of the outer stamens changed into stalked glands.

The sub-genus *Hepatica* is now included in *Anemone*, and may be distinguished by having an involucre of 3 entire leaflets just under the flowers, and a calyx of 6-9 petal-like sepals.

Culture and Propagation.—*Anemones* are best grown in a rich sandy loam, but most of them will thrive in ordinary garden soil. Where special treatment is required for any particular species, directions will be found in the proper place.

There are various methods of increasing Windflowers, and although division of the rootstock and cuttings of the roots are employed in autumn or early spring, most of the species may be obtained from seeds. These should be sown as soon as ripe in pans or boxes, and may be protected in a cold frame. The other directions given under Seed Sowing at p. 42 will be found useful.

A. alba.—A Siberian species about 6 in. high, with ternate or quinate leaves, purple on the underside; segments deeply toothed at top. Flowers in June, white, rising singly above the leaves, and having 5 obovate, concave sepals. May be used in borders or rockeries, in deep fibrous loam. Increase by seed or division.

Culture &c. as above.

A. albana.—A handsome and distinct dwarf species 4-6 in. high, found in a wild state from the borders of Armenia across Central Asia to Siberia, growing on the mountain sides. The nodding cup-shaped flowers are produced very freely in April and May, and although only of a dullish yellow, they look very handsome over the green carpet of foliage. After the flowers have withered, the seed-heads present a very ornamental appearance. Forms with purple or violet flowers have been recorded, but do not appear to be in cultivation.

Culture and Propagation.—This species grows well either in the ordinary flower border, or in the rockery in ordinary

garden soil. It prefers an exposed sunny spot, and will live for several years without being disturbed. Seeds ripen freely and may be sown as soon as ripe in cold frames. The young plants are pricked out and grown on but will not begin to flower until the third year, according to Mr. Wolley Dod.

A. alpina (*Pulsatilla alpina*).—A very handsome alpine species from the mountains of Central Europe, growing from 6 to 24 in. high. Leaves biternate with pinnate and deeply serrated lobes, sometimes smooth, and sometimes covered with long crowded silky hairs. Flowers produced in May, with 6 spreading elliptic sepals varying in colour from white to cream, white and purple, and yellow.

The variety *sulphurea* has soft yellow cup-shaped flowers, 2–3 in. across when fully expanded, the sepals having a silky down outside. The white-flowered form of *A. alpina* is a vigorous plant and delights in rich loam, peat and leaf soil, with the addition of a little lime rubble.

Culture &c. as above. The best way to increase this variety is to sow seed as soon as ripe in a rather moist peaty bed and allow the seedlings to remain for one or two seasons, and then transplant in the spring to a fully exposed, well-drained and moist position. A little lime rubble or old mortar mixed with the soil is usually beneficial to *A. alpina* and its varieties.

A. angulosa (*Hepatica angulosa*).—A beautiful species from Transylvania, 6–12 in. high, with leaves 3 in. broad, palmately 5-lobed, the lobes coarsely toothed. Flowers in February and March, 2 in. across, of a fine sky-blue, with numerous black anthers surrounding a tuft of yellow styles. Suitable for partially shaded places in the rock garden, margins of borders, shrubberies &c., in deep rich soil. There is a fine variety called *atrocærulea* with large deep purple flowers.

Culture &c. as above. Increase by seed or division.

A. apennina (*Apennine Windflower*). A tuberous blackish-rooted species from S. Europe, growing about 6 in. high. The leaves of the stem are in whorls of 3, ternate with long blunt lobes, all somewhat pubescent; the root-leaves biternate. Flowers about 2 in. across, bright sky-blue, appear on single stalks in March.

There is a white (*alba*) and also a rose-coloured (*rosea*) variety.

Culture &c. as above. This species prefers sandy loam or peat, and thrives under the partial shade of trees. It makes a beautiful carpet of blue, and should be grown for this purpose in large patches. Increased by division.

A. baldensis.—A rare tuberous-rooted species about 6 in. high, native of Switzerland. The leaves are twice ternate with many-parted linear-lobed segments. The solitary flowers appear in May, and have 8–10 oblong oval sepals, white, hairy outside, and reddish tinged with blue.

Culture &c. as above. Shady parts of the rockery suit it best.

A. blanda (*Blue Winter Windflower*). A lovely tuberous-rooted species from Greece. It grows about 6 in. high and closely resembles *A. apennina*. Leaves 3-partite or cut, with stalked or sessile 3-partite, cut segments; those of the involucre deeply cut and stalked. The deep blue flowers, each nearly 2 in. across, appear in winter or early spring, having 9–14 oblong linear sepals. The variety *scythinica* from N. Kurdistan has pale blue and white flowers.

Culture &c. as above. This species likes a rich, light, and well-drained loam and a warm sheltered place in rockeries sunny banks, or warm grassy slopes. Increase by seed or division.

A. coronaria (*Poppy Anemone*).—This is an important species, inasmuch as it has given rise to the many single and double florists' varieties which appear in such abundance in the early spring and summer, are so varied in colouring, and so popular in price. The typical species grows about 6–9 in. high, and has ternate deeply cut leaves with numerous narrow pointed segments. The flowers have 6 oval rounded sepals varying from red to white, purple and pink. It is a native of S. Europe.

Culture and Propagation.—The Poppy Anemone thrives in warm deep loam. The roots of the more select varieties may be taken up when the leaves wither, and planted at intervals in September and October or from January to March to secure a succession of flowers. If allowed to remain in the ground, however, it often happens that the warm rains of late summer will cause the plants to

grow and flower again later in the year if the weather is mild.

Seeds, which should be selected from the finest varieties, may be sown as soon as ripe in a spot where it will be possible to afford shade and moisture—the essentials to a rapid germination. The seedlings may be allowed to flower where sown or transplanted in September or October.

Among the many forms of the Poppy Anemone the following deserve special mention :

1. *The Chrysanthemum-flowered Anemone*.—This is a fine race of double-flowered Anemones, having the appearance of some Chrysanthemums or China Asters. There are many varieties, chiefly distinguished by colour, which varies a good deal, the principal tint being lilac-rose, deep violet, crimson, carmine, rose, purple, &c.

2. *Caen Anemones*.—These are well known by their vigorous growth, the great size of their flower stalks, and their large and brilliantly coloured flowers. Both single and double varieties are represented. The 'Cardinal's Hat' and 'Double Nice' Anemones are particularly fine forms, the first being deep scarlet with slight variations, the second of a beautiful rosy flesh colour.

A. decapetala.—A distinct N. American Windflower 12–18 in. high, with deep green 3-parted leaves, the lobes of which are cut into numerous linear segments. The creamy white or pale primrose flowers about 1–2 in. across appear in May and June.

Culture &c. as above. This pretty species, although perhaps not so ornamental as many of the other Windflowers, is valuable for planting in shady places.

A. Fannini.—A very beautiful and remarkable Windflower, native of Natal, where it grows at an elevation of 3,000–4,000 ft. In a wild state it attains a height of about 5 feet, and the roundish, angled, Rhubarb-like leaves a width of 2 ft. or more. In a cultivated state, however, it grows only about 2 ft. high, and the leaves rarely measure more than a foot in diameter. The beautiful sweet-scented star-like flowers are quite as large as in wild specimens. They appear in April and May and are 2–3 in. across, the oblong acute segments being at first greenish-yellow, but afterwards a pure snowy white

within, surrounding a mass of yellow stamens in the centre.

Culture and Propagation.—This species seems to be perfectly hardy at least as far north as Kew, when grown in rich and well-manured loamy soil in warm positions facing south. It is best left undisturbed for several years so that it may become thoroughly established. The leaves die down every winter and during that period the plants may be mulched with a layer of rich manure, and in the event of severe weather some litter or dry leaves may be placed over the crowns. The plants may be increased by carefully dividing the roots in spring or by sowing imported seeds under glass, afterwards pricking the young plants out.

A. fulgens (Scarlet Windflower).—This is a native of S. Europe, growing about 1 ft. high, with bright green 3-lobed cut and toothed leaves. The large solitary flowers which appear in May are 2 in. or more across, and of a brilliant scarlet-crimson colour, sometimes with a paler zone at the base around the jet black bunch of stamens in the centre.

Culture and Propagation.—This plant does best in rich loamy soil with a dash of lime in it, and is suitable for the partially shaded spots in the rockery or flower border. Stagnant moisture at the roots is fatal to it, hence the necessity for good drainage. The roots may be planted almost at any time, but during early autumn is the best time. Increased by dividing the roots, or from seeds. *A. fulgens major* is a fine form, and *A. Pavonina* (the Peacock Anemone) is a double form.

A. Halleri (Pulsatilla Halleri).—A Swiss plant about 6 in. high, with pinnate hairy leaves, cut into lance-shaped pointed divisions. Flowers in May, the 6 oval lance-shaped sepals being of a purple or deep lilac colour, and in strong contrast to the conspicuous bunch of yellow stamens in the centre. *A. Hackelsii* seems to be a form of this species, but differs in having more woolly stems, less finely cut leaves, and larger blossoms.

Culture &c. as above. This is a suitable plant for sunny positions in the rockery or the edges of flower borders. May be increased by seeds or division.

A. Hepatica (Hepatica triloba).—This is the common Hepatica of S. Europe. It grows 4–6 in. high, with heart-shaped

leaves, having 3 entire ovate pointed lobes. The blue flowers, with 6-9 sepals, usually appear about February, and are very attractive.

Among the many varieties of this species may be mentioned *alba* with pure white flowers; *cerulea*, single and double forms of which exist, with blue flowers; *rubra* (double and single) with reddish-pink flowers; *vilacina*, a pretty mauve kind; *splendens*, a single red; and *Barlowi*, a richly coloured sky-blue sport from the single blue, besides others.

Culture &c. as above. Hepaticas are charming spring flowers. They are of a deep-rooting nature, and prefer a rich porous soil in sheltered places. When left undisturbed for a few years they form fine clumps and often produce seedlings in favourable spots.

A. japonica (*Japanese Anemone*).—A fine autumn-flowering Japanese species about 2-3 ft. high with ternate unequally lobed and toothed leaves. The rosy-carmine flowers, which are borne on long stalks, are over 2 in. across, and have numerous conspicuous golden stamens in the centre, last a long time in perfection and make the garden gay from August up to the approach of frost.

The variety *alba*—also known as *Honorine Jobert*—is a splendid variety, with masses of pure white flowers each about 3 in. across.

The variety *elegans* (also called *rosea* and *hybrida*) is a variety with a more tufted habit, broader leaves, and pale rose flowers.

Culture and Propagation.—The Japanese Anemone and its varieties thrive in deep rich soil, and if allowed to remain undisturbed for several years produce a grand effect either in groups by themselves, or in the borders with other plants. They may be increased by division, or from root cuttings placed in a hotbed. It is very rarely indeed that *A. japonica* ripens seed in cultivation, but it has done so on one or two occasions. The seeds were sown with the result that varieties called *Lord Ardilaun* and *Lady Ardilaun* were raised. The latter is very fastidious and almost refuses to grow at all in some gardens, especially if the soil has been heavily dressed with rich manure. It has, however, been found to flourish in deep and well-dug loamy soil, with the addition of a little leaf mould at the time of planting. It grows about 4 ft. high,

and may be recognised by its Vine-like foliage and white flowers flushed outside with violet-purple. When well grown it produces seeds freely. *Lord Ardilaun* is usually better, but neither variety is at present equal in beauty and vigour to the parent. Another variety named *Whirlwind* has been introduced from America, and a nearly double-flowered variety has been raised in France under the name of *Coupe d'Argent*.

A. lancifolia.—A very rare tuberous-rooted species from Pennsylvania growing only about 3 in. high. The stalked ternate leaves are cut into lance-shaped roundly toothed segments, and the white solitary flowers with 5 ovate-acute sepals appear in May. A plant for the rockery.

Culture &c. as above.

A. multifida (*A. hudsoniana*).—This N. American species grows 6-12 in. high and has ternate leaves, the wedge-shaped segments of which are much cut into linear lobes. The small red, whitish-yellow or citron-coloured flowers appear in June, having 5-10 elliptic-obtuse sepals.

Culture &c. as above. Suitable for rockery or border. Increased by division or seed.

A. narcissiflora (*Narcissus-flowered Anemone*).—This very variable and beautiful species, native of Europe and N. America, grows about 12 in. high. The somewhat hairy radical leaves are 3-5-parted with deeply toothed lobes. The many-flowered umbels of white or purple blossoms appear in May, and have 5-6 ovate, blunt or acute sepals.

Culture &c. as above. This species prefers a somewhat calcareous or sandy soil in borders or rockeries, and may be increased by division.

A. nemorosa (*Wood Anemone*).—This charming native species adorns the woods and copses all over the country as well as in Europe and N. America. It has a horizontal woody rootstock and reaches a height of 4-8 in. The stalked leaves, which are covered with silky hairs when young, are divided two or three times into long narrow segments. The white (rarely purple) solitary flowers with 6 oval veined sepals are 1-2 in. across, and appear in April and May. The variety *robinsoniana*, which is probably identical with *cerulea*, has sky-blue flowers and is very beautiful. A new form of this called *Alleni* is a more vigorous grower and has larger and more

highly tinted blossoms. The double variety (*flore pleno*) is a pretty plant with white blossoms which last longer than those of the type. It is best grown in clumps in rich loamy soil.

There is also a single and double variety *rosea*, with rose-coloured flowers, and a double form called *bracteata flore pleno* having white flowers surrounded by a large involucre.

Culture &c. as above. Although the Wood Anemone is far more effective in its native state, it is a lovely plant for the rockery or flower border in somewhat shaded situations.

A. obtusiloba.—A Himalayan species with very hairy 3-lobed heart-shaped leaves cut into broadly wedge-shaped, deeply crenated segments. The flowers have 5 cream-coloured obovate sepals, and appear in June.

Culture &c. as above. A warm and sheltered position is required for this plant.

A. palmata.—This is a distinct tuberous-rooted plant about 6-8 in. high, from the Mediterranean region. The roundish heart-shaped leathery leaves are bluntly 3-5-lobed, slightly toothed and hairy. The large, glossy, golden-yellow flowers with 10-12 oblong obtuse sepals appear in May and June, opening in the sun. The double variety, *flore pleno*, and the white one, *alba*, are both pretty but very scarce.

Culture and Propagation.—*A. palmata* grows best in flat and dampish places in deep turfy peat, or loam and leaf soil, into which it roots deeply and forms strong clumps. It is increased by dividing the rootstocks or from seeds.

A. patens.—A species of N. Europe, with pinnate 3-parted toothed leaves, which appear after the flowers. In June the purplish or rarely yellow flowers with 5-6 sepals appear, being almost directly seated on the involucre. The variety *nuttalliana* is a pretty border plant about 1 ft. high from N. America. The flowers are purple and cream-coloured with connivent sepals hairy on the outside.

Culture &c. as above.

A. polyanthes.—A Himalayan species 12-18 in. high, with round 5-7-lobed and toothed leaves 2-4 in. across, borne on stout stalks 4-10 in. long. The white flowers 1½-2 in. across appear in May and June and are borne on branched umbels at the top of a stout stalk, the base of the umbel having

a leafy involucre of broadly wedge-shaped lobed and toothed bracts or stalkless leaves.

Culture &c. as above. This plant is not yet well known and is rather tender. It requires to be grown in warm sheltered spots and may be increased by careful division in spring as growth is about to commence.

A. pratensis (*Pulsatilla pratensis*).—This N. European species is closely related to the Pasque Flower (*A. Pulsatilla*), and differs chiefly in having smaller flowers with narrower and more acute sepals connivent at the base, and reflexed at the tips. It is about 6-12 in. high, with many-parted linear-lobed leaves, and dark purple drooping flowers which appear in May.

Culture &c. as above.

A. Pulsatilla (*Pulsatilla vulgaris*).—The Pasque Flower is a native of our chalky downs and limestone pastures, and also distributed throughout Europe to N. Asia. It grows from 3 to 12 in. high. The leaves, which spring from a stout woody rootstock, and develop after flowering, are thrice pinnatifid, with linear segments, those of the involucre being sessile and cut to the base into long linear portions. The dull purple flowers, each about 1½ in. across, appear in May and June, having 6 erect silky sepals, outer stamens reduced to glands, and fruits with long feathery tails. There are several varieties, among which may be mentioned *dahurica*, very dwarf, with very hairy oblong sepals; *lilacina*, with lilac flowers; and *rubra*, a red-flowered form with blunter sepals.

Culture and Propagation.—The Pasque Flower delights in deep, light and well-drained soil, forming strong clumps, and flowering freely, either in rockeries or the edges of borders. Increased by seeds or division.

A. ranunculoides (*Yellow Wood Anemone*).—A tuberous-rooted species of S. Europe, growing 4-6 in. high, with 3-5-parted leaves having deeply toothed somewhat trifid segments. The clear golden-yellow flowers, with 5 or 6 elliptic sepals, appear in March either singly or in pairs. There is a Pyrenean variety with purple flowers, and one named *pallida* with sulphur-coloured ones.

Culture &c. as above. This charming little plant is occasionally found naturalised in English woods, and likes the

same treatment as the Pasque Flower. It looks best grown in broad patches in light and rather sandy soil.

A. rivularis.—A very distinct plant from N. India. It grows about 2 ft. high, and has 3-parted hairy leaves, with cut and toothed wedge-shaped lobes. Large loose umbels of white flowers, with 5 oval sepals, and purple anthers, are borne in April.

Culture &c. as above. The shaded banks of streams or ponds, or damp situations in the flower border, suit this species best.

A. sibirica.—The typical form of this Siberian rock plant is very rarely seen. It is 6 in. high, with ternate leaves, and segments deeply toothed and ciliated. The white flowers, with 6 rounded sepals, appear in June.

Culture &c. as above.

A. stellata (*Star Windflower*).—This is identical with *A. hortensis* and *A. pavonina*. It is tuberous-rooted, and native of S. Europe, growing about 8 or 10 in. high. Leaves 3-parted, with deeply toothed, wedge-shaped lobes. The star-shaped flowers with 10–12 oblong bluntish sepals appear in April, and are red, purple, rose or whitish in colour. Double-flowered varieties are sometimes met with.

Culture &c. as above. This plant likes a warm and sheltered position in well-drained soil, and may be increased by seeds or division.

A. sylvestris (*Snowdrop Windflower*). This handsome species is 6–18 in. high and a native of Central Europe. It has creeping roots, from which arise ternate or quinate leaves, hairy beneath and with segments deeply toothed at the top, those of the involucre being stalked. The slightly drooping, pure white, solitary flowers, which in bud suggest Snowdrops, appear in April. When fully open they are 2–3 in. across, fragrant and with 6 elliptic sepals, and remind one very much of those of the white-flowered *A. japonica*.

The variety *major* has larger and better flowers than the ordinary form, and *flore pleno* is a new double form worth growing. *Baicalense* is a larger flowering variety, dwarfed in growth than the type, with flowers purple on the outside.

Culture and Propagation.—A light soil, rich in humus, and a shaded, moist situation are best for the Snowdrop

Anemone. Increased by dividing the roots as recommended above.

A. trifolia.—This is a native of the woody hillsides of Piedmont, the Tyrol, and Siberia, and is closely related to the Wood Anemone (*A. nemorosa*). It is 4–6 in. high, with a creeping habit and ternate leaves divided into ovate-lanceolate acute and toothed segments. The white flowers with 5 blunt elliptic sepals appear in April. There is a rose-coloured variety from Austria.

Culture &c. as above.

A. vernalis (*Pulsatilla vernalis*).—This is known as the Shaggy Anemone and grows about 2–8 in. high, the whole plant being covered with long tawny hairs. The pinnate leaves are cut into wedge-shaped lanceolate segments, while the erect bell-shaped flowers which appear in April are solitary and terminal with 5–6 oval sepals, whitish inside, violet and clothed with silky down outside.

Culture &c. as above. It is a native of the Alps and Pyrenees and should be grown in moist and well-drained sandy soil or peat. Increased by dividing the roots or by seed.

A. virginiana.—A N. American species 1–2 ft. high with ternate leaves cut into trifid, pointed and deeply toothed segments. About May the purplish-green or pale purple flowers appear, having 5 elliptic sepals, with a silky down on the outside.

Culture &c. as above. This species requires a damp situation and may be increased by division or seeds.

A. vitifolia (*Vine-leaved Anemone*).—A Himalayan species about 1–2 ft. high, related to the white Japanese Anemone. Leaves heart-shaped, 3–5-lobed, with pointed deeply toothed segments, the under surface and stems being covered with a white wool. The white flowers appear in July, and are 2 in. or more across, with eight oval-oblong sepals, thickly covered with down on the outside.

Culture and Propagation.—This plant does not thrive in all places, but where it does it is worthy of being naturalised. It requires a warm sheltered position and peaty soil.

ADONIS (PHEASANT'S EYE).—This genus includes a few species of handsome annual or perennial herbaceous plants

characterised by alternate leaves divided into numerous narrow segments, and solitary terminal flowers with 5-8 coloured deciduous sepals, 5-16 conspicuous petals often spotted at the base, and numerous carpels.

Culture and Propagation.—All the plants grow freely in ordinary garden soil, but prefer a rich, light sandy loam. They are excellent border and rockery plants, but to be seen at their best should be planted in good patches. They flower very freely for the most part, and, if anything, prefer slightly shaded situations to those fully exposed to the scorching rays of the sun. The annual kinds are very useful, and although occasionally a little weedy in habit they may be kept in bounds by a few short sticks and string.

The annual species must of course be raised from seed sown in the spring or autumn each year, either in the open border or in cold frames; the perennials may also be raised from seed in the same way, or by division of the roots in autumn or early spring.

A. æstivalis (Pheasant's Eye).—A S. European annual about 1 ft. high, with an almost simple lengthened stem. The deep crimson flowers having flat oblong obtuse petals appear in June.

Culture &c. as above.

A. amurensis.—This species is of recent introduction from N. China, and is somewhat like *A. vernalis*, but has denser foliage. The flowers are bright shining yellow, about 1½ in. across, and usually appear in January and February before any of the other species.

Culture &c. as above.

A. autumnalis (Red Morocco).—A native annual about 1 ft. high, with much-branched, very leafy stems and deep green leaves, very much divided into linear segments. From May to September the terminal solitary globose flowers appear, the sepals being greenish, and the broad concave petals scarlet, with a dark spot at the base.

This is an excellent border or rock plant. The fleshy flower stems, when cut, will last a long time in water or moist earth or moss, and the flowers will retain their beauty and freshness.

Culture &c. as above.

A. distorta (A. apennina).—This pretty perennial is a native of the Alps and is

intermediate between *A. pyrenaica* and *A. vernalis*. It grows 9-12 in. high, and produces its large bright yellow flowers just as those of *A. vernalis* are nearly finished.

Culture &c. as above. It is an excellent plant for massing in moist and partially shaded places in the rockery.

A. pyrenaica (Pyrenean Pheasant's Eye).—A Pyrenean perennial, with much-branched stems about 1 ft. high. The lower leaves are on long stalks with trifid petioles and many-parted segments, the upper ones stalkless, much cut, with linear entire divisions. The yellow flowers with 8-10 obtuse petals are almost sessile, and appear about July.

Culture &c. as above. It is difficult to establish in some gardens, and when first planted should be guarded from slugs. Once well established it is safer not to disturb this species. The soil may be replenished annually with a good mulching of well-rotted manure or leaf mould.

A. vernalis (Ox-Eye).—A beautiful European perennial about 1-2 ft. high with green feathery Fennel-like foliage. From March to May the bright yellow Anemone-like flowers, each with 10-12 oblong somewhat incurved petals, are borne at the tips of the branches. The sepals are purplish-green and about half as long as the petals, and the flowers are often 3-3½ in. across when fully open.

The variety *sibirica* has somewhat larger flowers than the type.

Culture and Propagation.—This is a graceful plant for the rockery and should be left alone for years in a rich moist sandy loam. It should be in a position more or less sheltered from rough winds, otherwise it is apt to become somewhat dishevelled in appearance.

It is often best raised from seeds sown as soon as ripe in sheltered spots in the border. The seeds, as a rule, do not sprout until the following spring. When large enough to be easily handled, they may be pricked out into a patch of rich soil, and in autumn—about the end of September—they will be fit for transplanting to their permanent quarters in the rockery or flower border. Plants from seeds, however, do not usually flower well until about three or four years old. Where large clumps are established therefore, and require removal, they may be divided to secure bloom more quickly.

A. volgensis.—A Russian species about, 1 ft. high, intermediate between *A. pyrenaica* and *A. vernalis*. The stems are much branched, with scale-like leaves at the base, and in early summer produce large pure yellow flowers, the sepals of which are smooth outside instead of pubescent as in the other species.

Culture &c. as above.

RANUNCULUS (BUTTERCUP ; CROWFOOT).—A genus with about 160 species of annual or perennial herbs having entire or much-cut leaves, and white, yellow, or red flowers, either terminal, solitary, or in panicles. Sepals 3-5 caducous. Petals conspicuous or rarely minute, equal in number to the sepals—or as many as 15—with a nectar-bearing scale at the base; stamens and carpels numerous, free and distinct.

R. aconitifolius (*White Bachelor's Buttons ; Fair Maids of France ; Fair Maids of Kent*).—A beautiful plant 24 in. high, native of Europe. Leaves palmately 3-5-lobed and deeply toothed, those of the stem cut into narrow lance-shaped lobes. The white flowers with oblong, wedge-shaped or rounded petals appear in May and June, sometimes few, sometimes many.

The double variety—*flore pleno*—popularly known as the 'Fair Maids of France' has pure snow-white flowers over half an inch across, and as symmetrical in form as a *Camellia*.

Culture and Propagation.—It is a pretty plant, easily grown in a moist and shaded spot, as under a north wall, where the flowers last longer in perfection than if the plants are grown in strong sunlight. Seeds of the single variety may be sown in the open border in spring, or in early autumn, or in pots or pans in cold frames. The seedlings may be pricked out and grown on for transplanting in spring or autumn, according to the period of sowing. The plants may also be increased by dividing the roots in spring, or about the end of September or October, and this is the better and probably the only way to increase the double variety, which is a much finer and more decorative garden plant than the single-flowered type.

R. acris flore pleno (*Double Buttercup ; Gold Knots ; Bachelor's Buttons*).—The type of this plant is the common Buttercup of our pastures and meadows, and is too well known to need any

description here. And besides, it is unsuitable for the flower garden. The double variety, however, is a pretty border plant, and very ornamental when in a good sunny position in moist soil. The bright yellow flowers are borne in button-like rosettes from April to September.

Culture &c. as above. The double-flowered Buttercup can only be increased by dividing the roots in spring or autumn.

R. alpestris.—A native of the Alpine chalky regions of Central Europe, growing 3-6 in. high. Leaves roundish heart-shaped, dark glossy green, 3-lobed, with the lobes deeply crenate and blunt at the apex; the leaves of the stem lance-shaped entire or occasionally more or less trifid. From April to August 1-3 white flowers each about an inch across are borne on a stem, the 5 petals being orbiculate or 3-lobed, and surrounding a conspicuous cluster of yellow stamens in the centre.

Culture &c. as above. This species grows well in moist, sandy soil, and is suitable for rockeries when grown in bold patches.

R. alexicaulis (*Snowy Crowfoot*). A beautiful species 3-12 in. high, native of the Pyrenees and Western Alps. It is easily recognised by its undivided ovate or lance-shaped tapering leaves, which clasp the stem at the base, and are smooth, glaucous, or with a few deciduous hairs on the edges. The snow-white flowers with yellow centres appear in April and May, 1-6 being on each stem. Occasionally the flowers are double.

Culture &c. as above. Grows well in deep moist loam, and may be naturalised among dwarf-growing plants in rather shaded situations.

R. anemonoides (*Anemone Crowfoot*). A pretty little plant from the Styrian Alps and Southern Tyrol. It is 3-6 in. high with glaucous green biternately divided leaves cut into linear segments. The rather large flowers, with numerous divisions in the petals, are greenish-white inside, pink on the outside, and appear during the summer months.

Culture &c. as above. It likes a moist well-drained soil and a cool situation. In some localities it is rather delicate, but once established in the clefts of the rockery it makes a pretty picture.

R. aquatilis (*Lodewort ; Ram's Foot*). A variable British Buttercup, found floating in shallow streams and pools of fresh water. The submerged leaves are much divided into slender linear lobes, while those floating on the surface of the water are usually 3-lobed, or absent. The beautiful pure white flowers, about $\frac{3}{4}$ in. across, are borne in great profusion during the summer months, and look like miniature single white Water Lilies on the bosom of the waters.

Culture and Propagation.—Seeds may be sown in pots standing up to the rims in water, or the roots may be divided in autumn after flowering is over.

R. asiaticus.—This native of S. Europe and Asia has given rise to all the garden Ranunculuses. It grows about 9 in. high, with erect stems, simple or branched at the base. The leaves are ternate or biterminate with toothed or deeply trifid segments. The flowers, which appear in summer, vary a good deal in colour, and are nearly always double in the cultivated forms, having very large obovate and very obtuse petals.

There are many varieties of the Garden Ranunculus under fancy names, but the following varieties or sections deserve special mention:—

R. a. sanguineus (*Turkey Ranunculus*).—This variety has simple stems and ternate leaves with toothed obtuse segments and double flowers of various colours such as orange, yellow, purple, or variegations of the same, excluding distinctly white or blue colours.

R. a. superbus is a pretty strain with large single, semi-double and double flowers of brilliant colours.

R. a. tenuilobus.—This variety has a stem more or less branched and much-cut leaves with sharp linear lobes, the flowers being white or yellow, rarely purple.

R. a. vulgaris (*Persian Ranunculus*). This ornamental variety has innumerable seedling forms in cultivation. It has a stem branched at the base; leaves ternate with sharp-pointed trifid segments, and double and single flowers of almost every shade but blue.

The above represent the main divisions into which the Asiatic Ranunculus naturally falls. But owing to the careful selection, hybridisation, and intercrossing by British and Continental gardeners,

extending over many generations, the wild forms have practically disappeared, and there are now an infinite number of varieties cultivated, being divided into groups, known as Scotch, Dutch, French, Italian, Persian, and Turban or Turkish. The Scotch and Dutch varieties are usually the finest forms of the Persian, and are dwarfer with double flowers edged and spotted. The French and Italian varieties are modifications of the Turkish, and are remarkable for their vigour and size. The Turkish forms are less variegated in colour than the others and have a large proportion of scarlet, white, yellow and orange self-coloured flowers, somewhat resembling Pæonies.

As the names in tradesmen's catalogues represent mere variations, it is unnecessary to give them here, as they would probably be obsolete in a very short time. It would therefore be better to make an up-to-date selection from the catalogues themselves.

Culture and Propagation.—The best time to plant the garden Ranunculus is about the end of February, although the work may also be done in October in favourable weather. The plants like an open situation but not too much exposed to summer sun, and the soil should consist of loam well mixed with decayed manure, rotten leaves &c., so that it may always be kept in a fairly humid state. The claws of the roots should be placed downwards, drills about 6 in. apart and 2 in. deep having previously been made with a hoe. The soil should be raked over the roots and made firm by patting with a spade. When the leaves appear, a little artificial manure or mulch of rotten dung may be given, the latter being preferable in dry seasons. As the roots deteriorate somewhat by lying dormant in the damp soil, especially in extra wet seasons, they should be taken up as soon as the leaves and flowers have withered, and stored in a cool airy place until the time for planting comes round again.

Seeds are obtainable as a rule only from the semi-double varieties. When the flower heads have withered, they should be cut off and placed in a paper bag, and hung up to dry and thoroughly ripen before being cleansed. The seeds may be sown in August and September in cold frames and in light rich sandy soil. The young plants should be protected

from frost during the winter months, but should have as much light and air as possible on all favourable occasions. About the end of April or May they will be fit for transplanting to the open ground. Seeds may also be sown out of doors about April and May, but if the seedlings are left in the soil for the winter, they should be protected by lights. Seedling plants commence to bloom well about the third or fourth year.

From the old roots there are often offsets. These may be placed by themselves and sown like seeds the following spring.

R. bulbosus flore pleno (*Double-flowered British Buttercup*).—This is a very pretty form of the common bulbous Buttercup of meadows and pastures. It grows about 12 in. high and produces numerous double yellow flowers during the summer. It is suitable for borders.

Sometimes the flowers are singularly prolific. From the centre of one arises another, and from this second one sometimes a third.

Culture &c. the same as for *R. acris flore pleno*.

R. bullatus.—An interesting species from N. Africa and Corsica, having tufts of oval toothed and more or less wrinkled leaves arising from a knotty rootstock. The fragrant yellow flowers appear late in the year and are therefore liable to injury from frost.

Culture and Propagation.—This species is too tender for the outdoor flower garden except in the warmest parts of the south and west. It may, however, be flowered in cold frames or greenhouses for the winter. New plants are obtained by dividing the rootstocks after the leaves and flowers have withered.

R. cardiophyllus (*Heart-leaved Buttercup*).—This hairy or pubescent plant is a native of N. America, and grows about 12 in. high. The root-leaves are roundish heart-shaped, crenate and much cut, the stem-leaves being palmately cut with linear deeply crenate lobes. The large golden flowers appear in May.

Culture &c. the same as for *R. acnitifolius*.

R. carpaticus.—A handsome Hungarian perennial about 1 ft. high, having creeping rootstocks and roundish palmately lobed leaves with crenate margins. The bright golden-yellow flowers,

which appear in May and June, are about 2 in. across, and are very attractive when in masses.

Culture &c. as for *R. alpestris*.

R. cassubicus.—A species 6 in. high, native of Northern and Eastern Europe. The lower leaves are stalked, smooth, kidney-shaped and crenate, those of the stem being divided into linear toothed lobes. Flowers in June and July.

Culture &c. the same as for *R. acnitifolius*.

R. chærophyllus (*Chervil-leaved Buttercup*).—A hardy tuberous-rooted species from Portugal, 8–12 in. high. Leaves stalked, much-divided segments, very narrow stems slightly downy. Flowers bright glistening yellow, over an inch across, with persistent non-reflexed sepals.

Culture &c. the same as for *R. acnitifolius*.

R. cortusæfolius.—This fine species is a native of Teneriffe and reaches a height of 3–5 ft. in the very mildest parts of this country. The leaves are very large, and like the branching stems more or less hairy; the lower ones are heart or kidney-shaped, lobed with coarsely crenate edges, the upper ones being almost stalkless, 3–5-parted, those near the flowers lance-shaped. The large glistening yellow flowers are 2 in. or more across, and are borne in erect corymbs in early summer.

Culture &c. the same as for *R. Lyalli* below. Except in the very mildest parts, it would be safer to treat this plant as tender, and give protection in winter by covering the rootstock with coco-nut fibre, ashes &c.

R. crenatus.—A charming Hungarian species about 6 in. high, with pure white flowers which appear in June and July, and rather remind one of those of *R. alpestris*. The petals, however, have crenate edges, and the flowers are only produced singly on the stems.

Culture &c. as above for *R. alpestris*.

R. creticus macrophyllus.—A native of the Greek Archipelago with branched slightly hairy stems and leaves, the latter being very deeply cut with slightly rounded teeth. The golden-yellow flowers appear in May, and the plant reaches a height of about 1 ft.

Culture &c. the same as for *R. Lyalli*.

R. Ficaria (*Figwort; Lesser Celandine; Pilewort*).—This British plant would be very beautiful in gardens if it were not such a rank weed. Once established it is difficult to eradicate, and hoeing only serves to propagate it by dividing the small club-like roots. Hand-picking is the surest way of ridding beds and borders of it. It is easily recognised by its heart-shaped bluntly angled or crenate shiny green smooth leaves, radiating on the ground from a short stem, and flowering from early March till May.

R. glacialis (*Glacier Buttercup*).—This plant is found high up on the Alps and Pyrenees near the snow line. It is 3-6 in. high, with leaves usually smooth, the upper ones sometimes hairy, palmately 3-parted or ternate with lobes deeply cut. The flowers appear in summer, one to five on a stem, and are white, tinged with purplish-rose outside.

Culture and Propagation.—Deep, gritty, peaty soil and a cool, damp spot in the rockery suit this plant best. *R. gelidus* and *R. roseus* are forms requiring the same treatment.

R. Gouani.—A vigorous-growing Pyrenean Buttercup about 18 in. high, with slightly downy 3-5-parted leaves, and bright yellow flowers, about 2 in. across, produced in May and June.

Culture &c. the same as for *R. aconitifolius*.

R. gramineus (*Grass-leaved Buttercup*).—A native of S.W. Europe, 6-12 in. high, with lance-shaped linear uncut leaves, arising from fascicled roots, and yellow flowers borne one to three on a stem in May and June. The variety *flore pleno* has double flowers.

Culture &c. This is the same as for the varieties of *R. asiaticus*. *R. gramineus* likes a sandy calcareous soil in moist and semi-shady spots. When grown in large masses it looks very effective in the rockery.

R. Lingua (*Greater Spearwort*).—This is a native of our marshes and ditches, about 3 ft. high, and is suitable for the margins of lakes, streams, bogs &c. The leaves are stalkless, lance-shaped, entire or toothed, 6-10 in. long, with parallel and reticulated veins. The handsome flowers about 2 in. across are borne in panicles from July to September, and are bright yellow in colour.

Culture &c. the same as for *R. aconitifolius*. Besides seeds and division, plants may also be raised from the bulbils which often form in the axils of the older leaves.

R. Lyalli (*New Zealand Water Lily; Rockwood Lily*).—A very handsome species 2-4 ft. high, from New Zealand. Leaves peltate, smooth, on long stout stalks, the blade being roundish, concave, thick, and leathery, and sometimes more than 12 in. in diameter. The waxy white flowers appear in spring and are 4 in. across, the petals being broadly wedge-shaped.

Culture and Propagation.—*R. Lyalli* cannot be considered perfectly hardy, except in the mildest parts of the country. It should have a sheltered nook from the north and east winds, and deep peaty soil, and is best left alone where it is already doing well. It can be raised from seeds, provided they can be imported in good condition. They are best sown as soon as ripe, or when received, in light rich soil under glass. When the young plants can be easily handled they may be pricked out so as to give more room for growth. Afterwards, when they require still more space, they may be potted up singly and kept in cold frames until they have become sufficiently strong and well-established to warrant their removal to the open border or rockery. On the whole this is a difficult Buttercup to grow well. It is probably 'coddled' too much.

R. millefoliatus.—A plant about 1 ft. high, with stems almost leafless, erect, hairy, and single-flowered, native of S. Europe. Leaves very much cut up into slender linear segments. The solitary yellow flowers appear from May to July.

Culture &c. the same as for *R. aconitifolius* or *R. amplexicaulis*.

R. monspeliacus.—A handsome plant 12-18 in. high, native of S. Europe. Leaves woolly, the lower ones 3-lobed, the lobes wedge-shaped, trifidly toothed; the upper ones 3-parted with entire linear lobes. Flowers bright glistening yellow, more than an inch across, appearing in April and May.

Culture &c. as for *R. aconitifolius*.

R. montanus (*Mountain Buttercup*). A dwarf plant 3-6 in. high from the alpine pastures of the mountain ranges of Europe. Leaves smooth, the lower ones roundish

3-parted, with 3-fid blunt segments; the upper ones stalkless, 3-5-parted into linear entire lobes. The solitary yellow flowers, somewhat larger than those of *R. acris*, appear from May to July, and are borne on more or less downy stems.

Culture &c. the same as for *R. aconitifolius*. Easily increased by division.

R. parnassiæfolius.—A distinct-looking species from high elevations on the Alps and Pyrenees, 3-6 in. high, with velvety stems of a purplish hue. Leaves entire, woolly on the edges, rather heart-shaped, ovate or roundish, those higher up the stem being ovate lance-shaped. The snowy-white flowers, sometimes tinged with pink, are borne in June and July on hairy stalks.

Culture &c. as for *R. alpestris*.

R. pedatus.—A species about 1 ft. high from E. Europe. Lower leaves stalked 3-parted or pedate, with linear entire or bifid lobes; the upper leaves are stalkless, and more or less linear or cut. The yellow flowers appear in May or June.

Culture &c. as for *R. aconitifolius*.

R. repens flore pleno.—This double-flowered yellow variety is often cultivated, but the single-flowered variety—a native of Britain—is a more or less troublesome weed, and best kept out of the flower garden.

Culture &c. the same as for the double variety of *R. acris*.

R. rutæfolius (*Rue-leaved Buttercup*). This grows near the limits of perpetual snow on the Alps, and is 3-6 in. high. It has distinct foliage, much cut and deeply divided, and yellow flowers with 8-10 oblong petals, usually borne in early summer. There seems to be a white-flowered variety in cultivation.

Culture &c. as above for *R. alpestris*.

R. Seguieri.—A handsome species from the Alps, with deeply cut dark green leaves, and fine white flowers which are produced in May and June.

Culture &c. as for *R. aconitifolius*.

R. spicatus (*Spiked Buttercup*).—A beautiful plant 12-18 in. high, which dies down early in summer and re-appears in September and October. Leaves somewhat hairy, roundish, and 3-lobed. The large bright yellow flowers appear in spring, 1-3 on a stem, the carpels in the

centre being elevated in the form of a spike. Native of N. Africa and Sicily.

Culture and Propagation.—This species may be divided after the flowers and foliage have withered. Seeds may also be sown as soon as ripe in the open border in special spots, or in pots or pans in cold frames. The seedlings are pricked out when large enough, and afterwards transferred to the open ground when sturdy enough to look after themselves. In the colder parts of the kingdom a little protection is needed in winter, with a little bracken, or a handlight over the plants.

CALTHA (MARSH MARIGOLD).—A small genus of herbaceous perennials with stout creeping rootstocks, and radical heart-shaped leaves. Flowers few, terminal, white or yellow. Sepals 5 or many more, coloured, deciduous. Petals absent. Carpels many, sessile, becoming many-seeded follicles when ripe.

Culture and Propagation.—The various forms of the Marsh Marigold are easily grown on the margins of lakes, rivers, streams &c., or even in the ordinary flower border in a moist spot. They are most effective in large clumps and may be increased by division of the rootstock. Seeds of the single-flowered varieties may also be sown as soon as ripe in pots or pans of loamy soil stood half their depth in water. As the seeds often do not sprout until the following spring, they should not be thrown away in autumn under the impression that they are useless.

C. alpina.—A distinct and beautiful plant 1-2 ft. high, with a bold vigorous habit, resembling that of our native Marsh Marigold. The leaves are roundish heart-shaped or reniform with crenate edges, while the upper stem leaves are coarsely toothed and nearly always sessile. The rich orange-yellow flowers are larger than those of *C. palustris*, but appear about the same period. From a botanical point of view this plant may be only a variety of *C. palustris*, but it is quite distinct enough for garden purposes.

Culture &c. as above.

C. palustris.—This is a well-known native of our marshes, margins of rivers, ditches &c., with stems 1-2 ft. high and large rounded kidney-shaped leaves toothed on the margins. The brilliant golden-yellow flowers are 1-2 in. across

and borne on furrowed stalks from March to June.

There are several forms among which may be mentioned the double-flowered *nana plena* and *monstrosa plena*; and the single-flowered *purpurascens* from S. Europe, with purplish shoots; *biflora*, a twin-flowered form from N. America; *parnassifolia*, a dwarf only 3-4 in. high, also from N. America, with heart-shaped ovate toothed leaves; and *leptosepala* from California with white flowers about $1\frac{1}{2}$ in. across.

Culture &c. as above.

C. radicans is a native of Scotland, and somewhat rare. It is probably only a form of *C. palustris*, but is distinguished by its deltoid sharply toothed leaves, and dwarf habit. The yellow flowers appear in May and June.

Culture &c. as above.

TROLLIUS (GLOBE FLOWER).—A genus of about nine species of perennial erect herbs with alternate leaves palmately lobed or cut, and solitary or few large yellow or lilac flowers. Sepals 5-15 petal-like; petals 5-15, small, narrow, with a very short claw, and blade with a glandular pit at the base. Stamens numerous. Carpels 5 or more, becoming follicles when ripe.

Culture and Propagation.—The Globe Flowers or Globe Buttercups will grow in ordinary garden soil, but to obtain luxuriant growth and freedom of flowering they should be planted in rich damp soil, and may be naturalised near the edges of ponds, streams or marshy places.

The plants may be increased by dividing the rootstock in autumn or spring, the former period preferred, as the disturbed plants can make new roots before the winter sets in fairly. If divided in March, the bitter cold and drying winds of that period do a good deal of harm and weaken the plants.

The Globe Flowers may also be raised from seed sown in pans or boxes in spring and planted out in the autumn, but it takes two or three seasons for the seedlings to become really fine flowering plants.

T. acaulis (*Stemless Globe Flower*).—A native of the W. Himalayas, 4-6 in. high, with very dwarf stem and 5-parted leaves. Its bright golden flowers, each about 2 in. across, are borne in July, the

7 sepals being broadly oval obtuse, and the 14 petals narrowly wedge-shaped.

Culture &c. as above. This plant prefers a fine peaty soil in a moist spot.

T. altaicus (*Altaian Globe Flower*).

A species 12-18 in. high with much-divided leaves, and pale orange or yellow flowers about 2 in. across, having 10, often 15-20 broad obtuse occasionally crenulate sepals.

Culture &c. as above.

T. asiaticus (*Asiatic Globe Flower*).

A handsome free-flowering species from N. Asia, China, and Japan, 12-18 in. high and closely resembling *T. europæus*. Leaves deeply divided and cut. Flowers deep yellow with 10 spreading sepals, and 10 petals longer than the stamens. There is a good deal of variation in this species owing doubtless to its somewhat wide geographical distribution. *Japonicus* or *Fortunei*, and 'Orange Globe' with rich orange-yellow flowers, may be mentioned as fine varieties; also *albus* which has very pale yellow flowers—not white, as the name would imply; and *major*, with large blossoms.

Culture &c. as above.

T. caucasicus.—A pretty Caucasian perennial 9-12 in. high with leaves deeply divided into 5-7 lobes. The large globular orange-yellow flowers appear in May and June.

Culture &c. as above.

T. europæus (*Boits*; *Common Globe Flower*; *Golden Ball*).—A native species growing in subalpine pastures and copses, having stems 6-24 in. high. The lower stalked leaves are somewhat roundish, 5-parted with wedge-shaped lobes; the upper ones being smaller and without stalks. The flowers are about 2 in. across, pale yellow, with roundish concave sepals, and oblong petals, appearing from June to August. They emit a fragrant odour, and seen at a distance appear to be semi-double, somewhat resembling forms of *R. asiaticus*.

There are many forms in cultivation, such as *albus*, *superbus*, a fine late one, *aurantiacus*, and *napellifolius*, a somewhat dwarfier and more showy kind, while *giganteus*, as the name implies, has larger flowers than the others.

Culture &c. as above.

T. laxus (*T. americanus*).—A native of N. America, 6-9 in. high with palmately

cut leaves. Flowers appear in May, pale greenish-yellow or nearly white, about $1\frac{1}{2}$ in. across, with 5 or 6 spreading sepals, and 15–25 small petals much shorter than the stamens.

Culture &c. as above.

T. patulus.—A Siberian species 3–12 n. high with golden-yellow flowers.

Culture &c. as above.

HELLEBORUS (HELLEBORE; CHRISTMAS ROSE, and BEAR'S FOOT).—A genus containing about twelve species of erect perennial herbs, with more or less leathery leaves palmately, pedately or digitately lobed. Flowers solitary or in panicles, white, greenish, yellowish, or purple in colour. Sepals 5, regular, petal-like, persistent. Petals small, tubular, two-lipped. Carpels numerous, separate or cohering at the base, when mature (follicles) opening at the top.

Culture and Propagation.—Hellebores should be grown in deep rich loamy soil, in damp and rather shaded places, such as under trees or at the foot of a north wall. As the flowers appear during the cheerless and often rainy winter months, it is well to have the plants where they can be protected, if necessary, from the damaging effects of mud splashes. The Christmas Rose (*H. niger*), for example, has most beautiful white flowers in winter, if protected with a glass light, or even a piece of canvas, when in bloom.

Hellebores are chiefly increased by dividing the rootstock after flowering. They may also be obtained by the slower process of sowing seeds when new varieties or variations of old ones are desired or expected. The seeds may be sown in rich soil, in pots or pans, in cold frames as soon as ripe. The following spring the seedlings will be fit for pricking out, so that with extra space they will become large and strong enough for transplanting about the end of September. Seeds may also be sown out of doors in specially prepared spots, not exposed to strong sunshine.

H. abschasicus (*Caucasian Christmas Rose*).—An evergreen Caucasian species about 1 ft. high, and leaves about 1 ft. across, divided into 5–7 bluntly lance-shaped widely spreading toothed lobes. Flowers from January to March green or purplish, nodding, about 2 in. across, with oval pointed sepals, yellowish-white sta-

mens and 18–24 petals. The variety *albus* has pure white flowers, which appear from February to May.

Culture &c. as above.

H. atrorubens.—A native of the woods and thickets of S. Europe. It is about 18 in. high, the lower leaves pedate with 5–9 lobes, the upper ones almost sessile and palmate. The deep purple flowers, changing with age to dull purple, appear about March and April, and have roundish sepals about 1 in. long.

Culture &c. as above.

H. caucasicus.—A Caucasian species about 18 in. high, with very glossy oblong leaves 3–4 in. broad. The pale green flowers appear from January to April, and have much-lapped sepals about $1\frac{1}{2}$ in. long. The variety *punctatus* is a garden hybrid with showy reddish-purple flowers spotted inside with dark purple. A newer form called *nigricans* is recognised by its bluish-black flowers.

Culture &c. as above.

H. colchicus.—This is a native of Asia Minor, and is perhaps the best of the red or crimson Hellebores. It is about 18 in. high, with very large, pedate, toothed, and distinctly veined leaves, divided 5–7 times. From three to six bright deep purple flowers, with yellow stamens, are produced well above the foliage from January to the end of March. The flat sepals are sometimes rounded in shape, and overlap each other.

H. colchicus has been crossed with *H. guttatus* and other species, the results being decided acquisitions to the garden. One variety—*coccineus*—has large handsome drooping bell-shaped blossoms of a beautiful plum purple suffused with red.

Culture &c. as above.

H. foetidus (*Stinking Hellebore; Setter Wort; Bear's Foot*).—A very distinct and ornamental evergreen native species, growing in chalky pastures and thickets, forming luxuriant tufts 2–3 ft. high. The lower leaves are stalked, divided 5–7 times into linear, toothed segments. The green flowers, 1 in. across, tipped with purple, are borne on drooping panicle cymes in February and March.

Culture &c. as above.

H. lividus (*H. corsicus*).—A native of Corsica, about 18 in. high, with smooth trifid leaves, the segments being oblong, lance-shaped and sharply toothed; from

10 to 20 pale green flowers with nearly flat and spreading sepals appear in March in a deltoid corymb.

Culture &c. as above.

H. niger (*Common Christmas Rose*). This beautiful and well-known plant is a native of Central and Eastern Europe and W. Asia. It grows 6-18 in. high, with smooth leathery pedate leaves cut into 5-10 lance-shaped segments. From 1-3 flowers, each 2-3 in. across when fully expanded, are borne on a stem from Christmas onwards. They vary in colour from pure waxy white to a delicate blush tint.

Among the varieties of this species may be mentioned: *altifolius* or *maximus*, which has large flowers white inside, tinged with rose outside, becoming deeper coloured with age. The leaf-stalks are also mottled with purple; *angustifolius*, of which there are two forms: one, the 'Manchester,' with leaf and flower stalks, pale green and without spots, and numerous flowers pure white throughout; the other, the 'Scotch,' a dwarf compact plant with flowers pure white within, slightly tinged with rose outside; *Madame Fourcade* and *major* are varieties with white flowers, the latter being particularly free flowering.

Culture &c. as above. This species may be slightly forced by simply lifting the clumps and placing them in a cool greenhouse for the flowers to open in all their purity. The blooms are in great demand with florists at Christmas time.

H. odorus (*Sweet-scented Hellebore*). This Hungarian species is about 18 in. high, with pale green leaves veined with white, those of the root stalked, pedate, with 6-8 lance-shaped regularly toothed segments. The green, sweet-scented drooping flowers, each about 2 in. across, appear from February to April. The variety *purpurascens* is dwarfer than the type, and has purplish-red flowers with rounded overlapping sepals curved in at the edges, and white stamens.

Culture &c. as above.

H. olympicus (*Olympian Hellebore*). A handsome species 1-2 ft. high, native of Greece. Leaves digitate, pedate, or palmate, cut into 5-7 linear oblong smooth lobes with toothed margins. The purplish flowers, with roundish sepals,

and yellowish stamens, appear from February to April, two or three being on one stem.

Culture &c. as above. This plant requires a somewhat warmer situation than the other species and does well in sheltered and sunny spots in the border or rocky.

H. orientalis (*Lenten Rose; Oriental Hellebore*). — A fine species, native of Greece and Syria, and growing 8-24 in. high. Leaves much divided, and somewhat downy when young, and cut into 7-9 more or less lance-shaped toothed segments. The large rosy flowers with overlapping sepals appear from February to May, two to six blossoms on a stem. Several vigorous hybrids have been raised by crossing this species with the white-flowered *H. niger* and the purple form of *H. odorus*.

Other varieties, often described as species, are *antiquorum*, which differs from the typical *H. orientalis* by its smooth leaves, and white flowers softly suffused with pink and grey; and *guttatus* with 5-7 white flowers on a stem, 2 in. across, dotted with purple; *subpunctatus* is a form of *guttatus*, with white flowers faintly spotted with green inside.

Culture &c. as above. Lenten Hellebores are best seen to advantage when left undisturbed for several years. They thrive in a deep rich and well-drained loam in positions that are fairly well sheltered, either by shrubs or walls, from keen cold winds. Among the numerous forms, to which many fancy names have been given, only those with clear and distinct colours should be selected and grown in large bold masses. The dull dead purple kinds are often too smeary to be attractive. A good mulching of well-rotted manure around the plants every autumn or winter will be of the greatest advantage in imparting fresh food to the soil, and increased vigour to the plants.

H. viridis (*Green Hellebore; Bear's Foot*). — A native of Europe, including Britain, growing about 18 in. high, with smooth, dark green leaves, the lower ones fully developing after flowering and cut into 5-7 narrow toothed segments. The green flowers are 1½-2 in. across and appear in March and April 5 or 6 at a time on the stems furnished with palmately cut leaf-like bracts.

Culture &c. as above.

ERANTHIS (WINTER ACONITE).—A genus of dwarf and pretty perennials with tuberous roots, palmately cut leaves and solitary yellow flowers. Sepals 5-8, regular, petal-like, deciduous. Petals small, clawed, with a scale at the base. Stamens and carpels numerous, the latter separate, becoming follicles when ripe.

Culture and Propagation.—There are only the species described below. They will grow in almost any soil, and are seen to the best advantage under trees or on banks in semi-wild situations. They are easily increased by division any time after flowering up to the end of September. Seeds may also be sown in the open border, or in pots or pans, but as a rule do not sprout until the following spring. Then they only produce a leaf or two for a few weeks and dry up, leaving only a small tubercle about the size of a pin's head in the soil. Every year this little tubercle becomes larger, and by the end of the third or fourth year is quite full grown and flowers freely.

E. cilicica.—This is a plant with more finely divided leaves and rather duller yellow flowers which appear earlier or later than those of *E. hyemalis* according to locality and circumstance.

Culture &c. as above.

E. hyemalis.—This, the best known species, is a native of W. Europe and grows 3-8 in. high. The yellow sessile flowers appear soon after Christmas or New Year's Day and continue to appear well into March. There are 6-8 oblong sepals and a similar number of very short tubular petals.

Culture &c. as above.

E. sibirica.—A Siberian plant 3 in. or so high. The yellow flowers appear in March and April, having 5 oval sepals.

Culture &c. as above.

COPTIS (GOLD THREAD).—A genus of pretty evergreen bog plants, with ternately cut leaves and white flowers. Sepals 5-6, regular, petal-like, deciduous. Petals 5-6, small, hooded or linear. Carpels (follicles when ripe) numerous, separate.

Culture and Propagation.—These plants may be easily grown in moist sandy or peaty soil and increased by dividing the roots in autumn or spring. Seeds may also be sown as soon as ripe in pots or pans of sandy peat and placed in cold frames for the winter. The seedlings are pricked out when large enough into other

boxes or pots, and may be transferred to the open ground in spring during mild weather. They may be grown as an edging or border to Rhododendrons, Azaleas, Kalmias, and other plants of the *Erica* family (see p. 574).

C. asplenifolia.—A native of N.W. America and Japan, about 1 ft. high, with biternate leaves, cut into sharply toothed segments. Flowers white with 5 very long and narrow petals, dilated and hooded in the middle, appearing in early summer.

Culture &c. as above.

C. occidentalis.—A plant 6-12 in. high from the Rocky Mountains. Leaves trifoliate, with short-stalked broadly ovate leaflets. The white flowers have 6 non-hooded petals and appear in early summer.

Culture &c. as above.

C. orientalis.—A Japanese species 3-9 in. high. Leaves ternate, each of the divisions pinnate at the base, and pinnatifid above; lobes deeply cut. Flowers white, in early summer.

Culture &c. as above.

C. trifolia (*Gold Thread*).—A native of N. America, Asia, and Europe, 3-5 in. high, with bright yellow fibrous roots, from which the popular name is derived. Leaves trifoliate, with blunt toothed and slightly 3-lobed leaflets. The white flowers appear from April to July on slender stalks which spring from the roots.

Culture &c. as above.

ISOPYRUM.—A genus containing about seven species of dwarf slender perennial herbs, with ternately decomposed leaves and white flowers solitary or loosely paniculate; sepals 5-6, regular, petal-like, deciduous. Petals 5, very short and very variable in form, sometimes absent. Carpels (follicles when ripe) 2-20, separate. Stamens sometimes as many as 10 in number.

I. thalictroides.—This European plant is the only species in cultivation and has very gracefully cut foliage somewhat resembling Maidenhair Fern fronds, or some of the Meadow Rues (*Thalictrum*). It is 9-15 in. high, and produces its small white flowers about April and May.

Culture and Propagation.—This is a beautiful plant for the rockery and grows well in sandy or ordinary garden soil. It may be increased from seeds sown in spring in the open border, or in pots or pans in cold frames, so that the seedlings

can be more readily attended to when large enough to handle easily. The roots also may be divided about the end of September, or in spring just as growth is beginning. This species makes a graceful edging plant.

NIGELLA (DEVIL-IN-THE-BUSH; LOVE-IN-A-MIST; FENNEL-FLOWER).—A genus of about 10 species of curious erect annuals, with alternate leaves cut into very narrow more or less finely cut pinnate segments. Flowers white, blue or yellow. Sepals 5, regular, petal-like, deciduous. Petals 5, clawed, with a small bifid blade. Carpels 3–10, more or less connate, and opening at the top when ripe to shed the numerous seeds.

Culture and Propagation.—Nigellas, or Fennel Flowers, will grow in any ordinary garden soil, and may be easily raised from seeds sown in the open border every spring. When the seedlings are large enough to handle easily they should be thinned out to about 6 in. apart. *N. damascena* and *N. hispanica* are the kinds most generally grown, but the other species as described below may also be tried.

They are all more or less ornamental and interesting plants in the rockery or flower border, and may be cut freely for bouquets, and for room decoration.

N. damascena.—A native of S. Europe and Asia Minor, 1–2 ft. high, with finely cut leaves and large white or blue flowers appearing in summer and surrounded by a mossy involucre. *Flore pleno* is a double-flowered variety, and *alba* has white flowers.

Culture &c. as above.

N. hispanica.—A species 1–2 ft. high from Spain and the south of France. Flowers in July and August, large, deep blue, and without any involucre. There is a white- and also a purple-flowered variety of this species.

Culture &c. as above.

N. Nigellastrum (*Gariidella Nigellastrum*).—This is the 'Star Nigella' of S. Europe. It has very finely cut leaves, and produces its brown and green flowers about July.

Culture &c. as above.

N. orientalis.—A curious species from Asia Minor. It is about 18 in. high, with pale blue-green foliage cut into long and narrow segments. The yellow flowers spotted with red appear in summer.

Culture &c. as above.

N. sativa.—This plant is supposed by some to be the Fitches mentioned in Isaiah. It is about 18 in. high and a native of S. Europe, N. Africa, and Asia Minor. The rather hairy erect stems are clothed with leaves cut into short linear diverging segments. The bluish flowers, without an involucre, appear in July.

Culture &c. as above.

AQUILEGIA (COLUMBINE).—A genus of erect perennial herbs, with ternately decomposed leaves, the segments of which are usually blunt. The flowers are as a rule very beautiful, vary a good deal in colour, being blue, white, yellow, purple, and scarlet, with intermediate shades, and are borne either singly or in panicles. Sepals 5, regular, petal-like, deciduous. Petals 5, concave, produced downwards between the sepals into a tubular horn-like spur, curved at the tips. Stamens numerous, the inner row sometimes reduced to scale-like staminodes. Carpels 5, separate, changing into opening follicles when ripe.

Culture and Propagation.—The Columbines are well-known and beautiful garden plants; most of them can be easily grown in ordinary soil, especially if it consists chiefly of loam with plenty of vegetable matter in it. Some of the more choice alpine kinds, however, require a little care in regard to soil and situation. They thrive best in well-drained, but withal moist, sandy soil, in half shady places with a northern aspect, and are suitable plants for the rockery. A good mulching of manure in autumn or early winter will be highly beneficial to the plants, and keep them in a vigorous condition for several years, and enable them to bring forth immense numbers of blossoms during the early summer months.

Columbines are easily increased either from seeds sown in spring in the open border; in the autumn in boxes or pans, placed in a cold frame; or by dividing the rootstock in autumn. As seeds are produced in great abundance as a rule, and cross-fertilisation is easily effected, the only sure way to secure an increase of a particular variety is by dividing the rootstock. Every shoot, if carefully detached and planted, will grow and make a strong plant the following season. On the other hand, a charming variety in form and colour may be obtained by planting seedlings. Where *A. chrysantha*, *A. sibirica*, and *A. vulgaris* are grown with other

species they sooner or later influence the progeny of the latter raised from seed, and ultimately crush the original types out of the garden. If seeds are not required the withering flower stalks may be cut down and very often in favourable seasons a second blossoming will take place in autumn as a consequence.

A. alpina (*Alpine Columbine*).—A beautiful species 9-24 in. high, from the Swiss Alps. The leaves are twice ternate, with segments deeply divided into linear lobes. The large drooping flowers which appear from May to July are 2-3 in. across when fully open, deep blue, or blue and white, with straight spurs somewhat incurved at the tips. Suitable for the rockery.

Culture &c. as above.

A. atropurpurea.—A Siberian plant 2-3 ft. high, with twice ternate leaves, and dark purple or bluish-violet flowers, almost 2 in. across, and two or three in a head with straight spurs. A border plant.

Culture &c. as above.

A. Bertoloni (*A. Reuteri*).—A pretty little alpine about 12 in. high, with small, dark, blue-green leaves. Flowers in June and July, violet-blue, about 1 in. across, with short knobby spurs.

Culture &c. as above.

A. canadensis (*Canadian Columbine*).—A very pretty border or rock plant, 12-24 in. high, native of N. America. The leaves have 3-parted bluntish segments, deeply toothed at the apex. The handsome and attractive flowers appear from April to June; they are scarlet, mixed with yellow, and less than 1 in. across, with straight spurs, and styles and stamens protruding. The variety known as *major* is somewhat larger in growth and blossom than the type, and is an improvement upon it.

Culture &c. as above.

A. chrysantha (*Golden Columbine*).—This fine vigorous species is a native of California and grows 3-4 ft. high, having twice ternate leaves. Flowers from May to August, many on a stem; sepals primrose-yellow, 1 in. long, tinted with purple at the tips; petals of a deeper yellow colour with straight slender spurs 1½-2 in. long. The variety *flavescens* (also known as *aurea*) has flowers of a uniform bright canary-yellow, tinged with red, and spurs somewhat incurved at the tips. There is also a dwarf form 12-18 in. high with

golden-yellow flowers, and numerous variations may be obtained by raising plants from seed.

Culture &c. as above.

A. cærulea (*A. leptoceras*; *A. macrantha*).—A lovely species for borders or foot of rockeries. It is a native of the Rocky Mountains, and 9-15 in. high, with large twice ternate leaves. Several flowers are borne on a stem from April to July, each one being 2½-3 in. across when fully open, and are blue and white in colour, sometimes tinted with lilac or claret, rarely pure white; spurs about 2 in. long, very slender, almost straight, and tipped with green. The variety *alba* (sometimes called *grandiflora*) is a rare and beautiful form with large pure white flowers. The variety *hybrida* is a vigorous grower of garden origin and produces numerous blue and white flowers. A double-flowered variety appeared some few years ago and is likely to remain constant.

Culture &c. as above. In some soils *A. cærulea* is apt to die out. Where this occurs it should be raised from seed annually.

A. flabellata.—A pretty Japanese species about 1 ft. high, with a black tuberous rootstock, and stiffish grey-green leaves cut into 3-5 lobes. The white flowers with short greenish spurs appear in early summer in great abundance, and combined with the dwarfness of the tufted plant make a good picture in the border or rockery.

Culture &c. as above. This Columbine may be grown in pots and gently forced in greenhouses in the early part of the year with good results.

A. formosa (*A. arctica*; *A. californica*; *A. eximia*; *A. f. truncata*).—A showy border plant from N. America, 2-4 ft. high with twice ternate leaves. The flowers appear from May to September, many on a stem, and have bright orange-red sepals about 1 in. long, with a green blunt tip and yellow petals; the spurs are ½-¾ in. long, slender, almost straight, distinctly knobby at the tips.

The plant known as *A. californica hybrida* is a beautiful hybrid with yellow sepals and petals, tinted with orange, and long slender orange-red spurs.

Culture &c. as above.

A. fragrans (*Fragrant Columbine*).—A handsome much-branched bushy species, 1½-2 ft. high, native of the Hima-

layas. The leaves are twice ternate, the upper ones downy and somewhat glandular. Flowers from May to July, few on a stem, white or pale claret-purple, agreeably fragrant, and slightly downy; spurs slender, twice as long as the truncated petals, slightly curved, and knobbed at the tips.

Culture &c. as above. This plant requires a somewhat warm and sheltered position in moist sandy soil.

A. glandulosa (*Glandular Columbine*). A very pretty Siberian plant 8-12 in. high, with twice ternate much-lobed leaves. Flowers from April to June, with large deep blue nearly oval sepals, and fine blue petals tipped with creamy white, the spur being stout and much incurved. The variety *jucunda* is a smaller plant, but very handsome, and is best treated as a biennial. Seeds may be sown every year to keep up a supply.

Culture and Propagation.—It is safer to divide this plant for increase before the leaves die down, as it is apt to perish, especially on cold soils, if divided when at rest. In many places *A. glandulosa* does not flower very freely, either because it is too often disturbed, or the soil is not sufficiently rich and well manured. Once the plants are established, they should receive a good dressing of manure every autumn or winter, and they will flourish for four or five years without being disturbed.

A. glauca.—A Himalayan plant 12-18 in. high, with twice ternate leaves of a blue-green sheen. Three to four fragrant white, claret-tinted flowers on a stem appear in June, having straight or slightly curved spurs about $\frac{1}{3}$ in. long.

Culture &c. as above. As this plant is somewhat tender it may not survive hard winters in unfavourable parts, and would therefore require a little protection. It should be given a warm dry spot.

A. longissima.—A native of Texas and Mexico, 3-4 ft. high, and closely related to *A. chrysantha*. The stems and leaves are covered with silky hairs, the under surface of the foliage being bluish-green. The pale yellow or whitish flowers tinged with red appear in summer and have spurs 4 in. or more long.

Culture &c. as above.

A. olympica.—A native of Greece, about 18 in. high, with 2-3 ternate blue-green leaves, and large delicate mauve

flowers with white petals and short blunt spurs. They appear about April and May and are very effective owing to the contrast in colour between the sepals and petals.

Culture &c. as above.

A. pyrenaica.—A pretty rock or border plant 9-12 in. high, native of the Pyrenees. Leaves 1-2 ternate, deep green with linear segments. Flowers from April to June, one to three on a stem, bright lilac-blue, with slender spurs nearly straight, about $\frac{3}{4}$ in. long, and scarcely knobbed at the top.

Culture &c. as above.

A. sibirica (*A. bicolor*; *A. garnieriana*; *A. speciosa*).—A pretty rockery plant about 12 in. high, native of Siberia, and having 2 ternate leaves. Flowers in June and July, many on smooth stems, bright lilac, with blunt sepals, the limb of the petals sometimes white; spurs stout, much incurved, $\frac{1}{2}$ - $\frac{3}{4}$ in. long.

The double-flowered form *flore pleno* is a more ornamental plant. It is similar in habit to the type, but has heads of double flowers, the spurs of which always point downwards instead of upwards. They are blue and white in colour, but sometimes yellowish, and present a very handsome appearance when seen in masses.

Culture &c. as above.

A. Skinneri.—A noble and distinct border species 2-3 ft. high, from the mountains of Guatemala, with leaves twice ternately divided and unequally lobed. The large handsome flowers are borne on slender stalks from June to August, with red or greenish lance-shaped sepals, small golden-yellow petals, and straight spurs about 2 in. long, and of a bright orange-red.

Culture &c. as above. This should be grown in warm sandy loam. Several forms, apparently hybrids between *A. Skinneri* and *A. vulgaris*, have appeared, and seem to possess a more vigorous constitution than the typical *A. Skinneri*. The flowers also vary a good deal in colour, as might be expected, and red, blue and yellow shades are not uncommon. These primary colours will serve to produce a vast number of intermediate shades in due course. Any exceptionally fine variety can only be kept pure by division of the rootstocks as advised above at p. 155.

A. Stuarti.—This is a splendid Columbine, closely related to *A. glandulosa*, and from a botanical point of view can only be regarded as a form of that species. It was raised by Dr. Stuart of Chirnside, N.B., by fertilising *A. vulgaris wittmanniana* with the pollen of *A. glandulosa*. It is, however, a much finer plant than the latter species, and produces its large attractive flowers—each about 4 in. across—in April and May. The sepals are of a deep and brilliant blue, and in striking contrast to the white and blue tubular and shortly spurred petals surrounding a bunch of bright yellow stamens in the centre.

Culture and Propagation.—This beautiful border plant likes a rich and deeply dug soil and is best raised from seeds sown as soon as ripe in the places where the plants are to bloom. Instead of pricking out the seedlings, they may be thinned out to 8 or 12 in. apart, in mild showery weather. The thinnings may be transplanted to other parts of the garden if required. The plants should not be disturbed for 3 or 4 years, but should have a good mulch of well-rotted manure every winter.

A. thalictrifolia.—A downy plant about 2 ft. high, from the Tyrol, having leaves with 3-stalked segments cut into deep oblong lobes. Flowers in June and July, 2-3 on a stem, lilac-blue, with oblong acute sepals $\frac{1}{2}$ in. long, and slender spurs.

Culture &c. as above.

A. transylvanica.—A beautiful and free-flowering Transylvanian species 1-2 ft. high. All its parts are quite smooth, and the lower leaves are twice ternate, with 2-3-lobed segments. The bright rich blue or purplish flowers are 2-3 inches across, and appear in great profusion during May and June, the ovate oblong sepals being distinctly clawed.

Culture &c. as above. It grows very freely and may be increased by dividing the roots in early autumn or spring. Closely related to *A. glandulosa*.

A. viridiflora (*Green-flowered Columbine*).—A somewhat pretty and distinct species from Siberia, 12-18 in. high, with leaves. Flowers sage-green, sweetly scented and very useful for cutting.

Culture &c. as above.

A. vulgaris (*Common Columbine*).—A native of our woods and thickets and

very valuable for its many pretty garden forms. It grows 1-3 ft. high, with almost smooth 2-3 ternate blue-green leaves. The drooping flowers are borne in loose corymbs from May to July, and are blue, dull purple, white, or various shades, including red in the garden forms. Spurs hooked and knobby at the tips.

There are very many forms—both single and double-flowered—to which it would be mere waste of time to give distinctive names. Mention, however, may be made of the following: *alba*, with pure white single flowers; *alba flore pleno*, with white double flowers; *cærulea nana fl. pl.*, very dwarf, with deep blue double flowers; *hybrida*, with lilac-purple sepals and white petals; *vervæmiana*, with variegated or yellow mottled foliage; and *wittmanniana*, a fine variety with large bright lilac-purple sepals 1-1 $\frac{1}{4}$ in. long, white petals, and curved spurs.

Culture &c. as above.

ANEMONOPSIS.—A genus containing only the following species:—

A. macrophylla.—A pretty hardy perennial 2-3 ft. high, native of Japan. It has large smooth and twice ternate leaves with coarsely toothed leaflets, and somewhat resembles an *Actea* in appearance. The flowers, which resemble those of *Anemone japonica*, but are rather smaller, appear in June and July in loose raceme-like clusters. Each flower consists of about 9 or more concave sepals, pale lilac inside, purple outside, and 12 or more linear oblong petals with a nectary-bearing hollow at the base.

Culture and Propagation.—This Japanese plant is hardy in most parts of the kingdom but may require a little protection with dry leaves, litter &c. over the crowns in the coldest parts. It flourishes in ordinary good and well-drained garden soil of a somewhat loamy and gritty nature, and may be increased by division of the roots about March. Seeds if obtained may also be sown in cold frames as soon as ripe, or in gentle heat in spring, and the seedlings planted out in May.

DELPHINIUM (LARKSPUR).—A genus of about 40 species of erect annual or perennial herbs, with alternate lobed or cut leaves. Flowers in racemes or panicles, blue, purple, pink, or white, rarely yellow. Sepals 5, petal-like, separate, or cohering below, the upper

one drawn out into a spur behind. Petals 2-4, small, the 2 upper having spurs within the sepaline spur, the two others spurless or absent. Stamens numerous. Carpels (follicles when ripe) 1-5.

Culture and Propagation.—Perennial Larkspurs will grow in almost any soil or situation, but are most luxuriant when given a deep mellow loam well enriched with rotted manure, and fairly moist. As the Larkspurs vary a good deal in height—from 2 to 6 or 8 ft.—they are suitable for planting in various situations. If in beds by themselves, a distance of 2-3 ft. should be between the plants, and greater distance still when in borders with other perennials.

About every third or fourth year the rootstocks may be divided and replanted. This is best done in spring, just when the plants have started into growth. Autumn division is not advisable, as the roots are apt to perish during hard winters, probably because the new ones have not had sufficient time to obtain a good hold of the soil.

As with many other flowers, so Delphinium can be made to bloom a long time by picking off the flowers or spikes as soon as they begin to fade. The side shoots are thus stimulated into growth, and give a fresh supply of flowers. It must, however, be borne in mind that this continual development of flowers has an exhausting effect on the plant's constitution, and this should be counterbalanced by heavy dressings of manure in either a solid or liquid state.

Besides the process of dividing the roots already mentioned, Larkspurs may also be increased by seeds or cuttings. Seeds of the perennial kinds are often very slow in germinating. Those of the annual species may be sown out of doors on a warm border in April, or better still in pans or boxes, from which the seedlings can in due course be pricked off into light rich soil. In early autumn the seeds may also be sown in cold frames, and the seedlings planted out in mild weather the following spring.

Cuttings of the perennial kinds are made of the tops of the young shoots in either spring or autumn. They should be inserted in somewhat sandy soil either singly in small pots, or several in a shallow box, and placed in a cold frame, excluding the air for a few days. When well rooted the young plants may be transferred to their permanent positions.

Besides the natural species described below, there are very many beautiful florists' varieties having single, double, and semi-double flowers in all shades of blue, lilac, lavender, purple and violet. As nurserymen are continually adding new varieties, a reference to their catalogues may be better than giving a list here, which would probably soon be out of date. The following are the most distinct natural Larkspurs:—

D. Ajacis (*Rocket Larkspur*).—A native annual of British cornfields, 12-18 in. high, with fine deeply cut leaves, and blue, white or pink flowers about 1 in. across, produced in long racemes in June and July.

D. Ajacis has given rise to very many varieties of annual Larkspurs, which vary a good deal in habit, and have a very extensive range of colouring among the single and double flowers. *D. Ajacis majus*, *D. A. minus*, *D. A. hyacinthiflorum*, and *D. A. ranunculiflorum* may be taken as types of the various sections cultivated.

Culture &c. as above. Seeds sown annually.

D. armeniacum.—Closely related is a newer species native of Armenia. It has the habit and general appearance of *D. Ajacis*, but is more vigorous in growth, and has soft, sky-blue flowers.

Culture &c. as above. Seeds sown annually.

D. azureum.—A perennial species from N.W. America, about 3 ft. high, with 3-5-parted, many-cleft leaves with linear lobes. The large beautiful sky-blue flowers are borne on erect racemes from May to July, the upper petals being all bearded, the lower ones hairy. The variety *album* has white flowers.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. brunonianum.—A rare species with a strong musky odour, native of Thibet. It is 6-12 in. high, the lower leaves being kidney-shaped and deeply divided; the upper ones 3-parted. The large light blue flowers with purple margins and black centre appear in June and July.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. cardinale (*Scarlet Larkspur*).—A handsome Californian annual 3-4 ft. high, with smooth and somewhat fleshy

deeply lobed leaves. The bright scarlet flowers, with distinctly yellow petal limbs, are produced in spikes during August. Owing to its long fleshy roots, this species should be grown in a good depth of rich soil.

Culture &c. as above. Seeds sown annually.

D. cardiopetalum.—A Pyrenean annual about 1 ft. high, with smooth ternate leaves cut into linear lobes. Flowers dark bluish-violet on crowded racemes in June.

Culture &c. as above. Seeds sown annually.

D. cashmirianum.—A native of Kashmir 12-18 in. high, with palmately lobed leaves 4 in. or more across, deep green, and slightly hairy. Flowers produced in corymbs in July, of a distinct pale blue, each 1-2 in. across.

Culture &c. as above. Best increased from seed sown in autumn in cold frames. The variety *atropurpureum* has much larger and deeper coloured flowers than the type. The variety *Walkeri* is distinguished by having dull yellow petals tipped with purple.

D. caucasicum.—A Caucasian species 1½-2 ft. high, with palmately lobed and toothed radical leaves, and lance-shaped acute bracts on the floral stems. The dark blue flowers which are borne singly in the axils of the bracts are about 1½ in. across, and are produced nearly the whole length of the stem.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. cheilanthum.—A species 2-3 ft. high from Dahuria. Leaves 5-parted with oblong pointed, sub-trifid, and somewhat toothed lobes. The dark blue flowers appear in September.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. Consolida.—A European annual occasionally found wild in England, 12-18 in. high, with leaves cut into narrow linear lobes.

This and *D. Ajacis* have given rise to a great number of garden varieties.

Culture &c. as above. Seeds sown annually.

D. dasycarpum.—This hairy-fruited species is a native of the Caucasus, and is

about 4-6 ft. high. The downy leaves have 5 lance-shaped lobes, somewhat trifid and deeply toothed at the apex. The rather large, beautiful blue flowers with brownish petals appear in June on simple downy racemes.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. elegans.—A N. American species 1-2 ft. high with smooth 5-parted leaves cut into cleft lobes and linear lance-shaped lobules. The dark blue flowers are borne on loose racemes in June and July. There is a double-flowered form.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. Emilie.—A fine Californian perennial 1½-2 ft. high. It grows upon sunny slopes in a wild state, with masses of *Calochorti*, and produces its trusses of deep blue flowers in June. As yet it does not appear to be well known in British gardens, and seeds have probably not yet been imported in quantity.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. exalatum (*D. elatum*).—A species 3-6 ft. high from N. America. Leaves 3-7-parted with wedge-shaped jagged lobes pointed at the apex. The blue or sometimes white flowers appear from June to August in erect spikes.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. formosum.—The native country of this fine species has not been fixed with any certainty, but it is supposed to be of Asiatic origin. It is 1½-3½ ft. high, with grey-green palmately lobed leaves, the lower ones stalked, the upper sessile and simply 3-parted. The flowers are borne on long spikes during the summer and autumn, and are of a fine azure-blue shaded with indigo; the spur is of a violet-blue, rather long, two-cleft, and rumped looking.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. grandiflorum.—One of the most beautiful Larkspurs, growing 1-3 ft. high, and native of Siberia and Dahuria. The light green leaves are smooth above, hoary beneath, and palmately cut into many narrow lobes. The large flowers, varying in colour from blue to white, are borne on spreading few-flowered racemes

from June to September, and have petals shorter than the sepals, the limb of the lower petals being entire and roundish.

There are many varieties of this species, the best of which is perhaps *chinense* or *sinense*, which differs in having a stiffer and more erect stem, and in the 2 lower petals being bearded with yellow hairs. *D. g. plenum* is a fine double-flowered variety; *album* has white flowers, of which there is also a double form. Other forms are *pallidum*, *rubrum*, *pumilum album* and *pumilum cæruleum*, the names of which give an idea of the colours.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. hybridum.—A native of Tauria, 3-4 ft. high, with many-parted linear-lobed leaves having dilated stalks sheathing at the base. The blue flowers, the 2 lower petals of which have white beards, appear on crowded racemes from June to August. The variety *ochroleucum* (also known as *albiflorum*), a native of Armenia, has whitish flowers, smooth outside.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. intermedium.—A European species 4-8 ft. high, with heart-shaped 5-7-parted leaves, the lobes of which are deeply serrated. In July and August the glaucous racemes of flowers appear, the sepals being blue, and the very hairy petals almost black. There is a great deal of variation in this species.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. laxiflorum.—A Siberian plant 4-6 ft. high. Leaves 3-7-lobed, the lobes being oblong, acute, and deeply cut; the upper leaves are more or less 3-parted with narrow entire lobes. Flowers in June, on loose branched racemes.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. mesoleucum.—The native country of this species is unknown. It grows about 3 ft. high, with somewhat downy stems, and has leaves rather dilated at the base with wedge-shaped segments, deeply serrated at the top. The flowers appear in June, having blue sepals and pale yellow or whitish petals.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. nudicaule.—A brilliant species 12-18 in. high from California. The

somewhat peltate fleshy leaves are 3-parted with numerous sub-divisions, which in the lower ones are orbiculate with notched lobes, and in the upper oblong entire. The flowers, which are borne on a loose raceme from May to August, have vivid red sepals inclining to orange, and clear yellow petals, the lower ones being spoon-shaped with a 2-cleft fringed lip; the upper ones elongated, prominent, hairy at the ends; the spur about twice as long as the smooth calyx. The variety *elatius* is taller growing than the species.

Culture and Propagation.—*D. nudicaule* grows best on raised ground in warm borders with light sandy soil. It is easily raised from seeds, but well-established plants may also be divided. General treatment as described above.

D. Requieni (*D. pictum*).—A biennial species about 18 in. high from S.W. Europe. Leaves on long stalks, the lower ones cut into 5 broad, wedge-shaped, 3-5-toothed lobes, the upper ones into 5 linear entire lobes. The bluish hairy flowers appear in June.

Culture &c. as above. Increased by seeds sown in cold frames as soon as ripe. The seedlings to be planted out in spring.

D. Staphisagria.—A large erect biennial 2-3 ft. high from S. Europe, with 5-9-lobed leaves. The blue flowers with whitish petals appear on loose racemes in May and have a very short spur.

Culture &c. as above. Increased by seeds sown in cold frames as soon as ripe. The seedlings to be planted out in spring.

D. tricorne.—A N. American species about 9 in. high, with 5-parted leaves cut into 3-5 narrowly divided lobes. The bright blue flowers appear in May.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. triste.—A native of Siberia, 2 ft. high, with 3-5-parted leaves, having somewhat pinnatifid sharp narrow lobes. The flowers appear on loose racemes from July to September, and are dark brown, the edges of the sepals being tinged with red, and the spur of a violet colour.

Culture &c. as above. Increased by seeds, division, or cuttings.

D. trollifolium.—A beautiful N. American Larkspur 2-4 ft. high, with stout

smooth or slightly hairy stems. The long-stalked leaves are divided into 5-7 incised and toothed lobes, and the bright blue flowers with a white centre are borne in loose racemes during the early summer months in May and June.

Culture &c. as above.

D. Zalil (*D. sulphureum*).—A beautiful tuberous-rooted species 6 ft. or more high, native of Afghanistan, with deeply cut leaves and tall spikes of soft yellow flowers during the summer months.

Culture and Propagation.—Unfortunately this species is somewhat tender except in sheltered sunny places in the south. It, however, flowers and seeds freely, but has a habit of dropping its leaves when in bloom. Although a perennial, it is best to raise seedlings in gentle heat every spring so as to have young plants ready for planting out in well-manured soil at the end of May. Or the seeds may be sown in cold frames as soon as ripe, so that the seedlings will be well advanced for planting out the following spring.

ACONITUM (ACONITE; MONKSHOOD; WOLFSBANE).—An extensive genus of ornamental and dangerously poisonous perennials with palmately lobed or cut leaves. Flowers in terminal racemes or panicles, blue, purple, yellowish, or white. Sepals 5, the upper one helmet-shaped, or like a monk's hood. Petals 2-5, small, the 2 upper with long claws hooded at the tip, the 3 lower minute or absent. Carpels 3-5 becoming follicles when ripe.

Culture and Propagation.—Aconites grow well in any garden soil, and if not disturbed for years will become splendid clumps, and produce masses of handsome flowers. As the roots have frequently been mistaken for Horse-Radish, care should be taken to keep the plants as far away from the kitchen garden as possible, and even from the ordinary flower borders, in case of accidents. Copses, shrubberies, or the edges of streams or ponds are suitable places for these plants to grow.

Aconites are easily increased by seeds or division of the roots in early autumn, but preferably in spring, as growth is about to commence. After performing the latter operation, the hands should be well washed as a precaution, or gloves may be used.

Aconites may also be raised from seeds sown as soon as ripe in the open border in half-shaded spots. Very often, however, they do not sprout until spring. The seedlings are pricked out into prepared soil for further growth, and allowed to remain until the autumn or the following spring before being shifted to their permanent positions.

There are a very large number of varieties, but the following are among the best for garden purposes:—

A. album.—A rare and handsome tuberous-rooted species 4-5 ft. high, native of the Levant. The large pure white flowers with erect helmet are freely produced in August.

Culture &c. as above.

A. angustifolium.—A tuberous-rooted Siberian species 2-3 ft. high, with deep blue flowers, having a closed hemispherical hood, produced in June.

Culture &c. as above.

A. Anthora.—A species, 1-2 ft. high, from the Pyrenees. The pale yellow flowers appear in July on downy panicles. There are several varieties of this species, among which may be mentioned *Decandollei*, *eulophum grandiflorum*, *Jacquini*, and *memorosum*, all with yellow flowers.

The black roots are more or less turnip-shaped and poisonous.

Culture &c. as above.

A. autumnale.—A European species 3-4 ft. high, producing its bluish-purple flowers from July to November.

Culture &c. as above.

A. barbatum (*A. squarrosum*).—A native of Siberia, 2-6 ft. high, with hairy leaf stalks. Flowers in July, creamy yellow, rather downy, having the middle sepals densely bearded.

Culture &c. as above.

A. biflorum.—A very rare alpine species, about 6 in. high, native of Siberia. The pale blue, usually twin flowers, downy outside, appear in June.

Culture &c. as above.

A. chinense (*A. Fortunei*).—A stately Chinese species 4-6 ft. high, with very bright and intense blue flowers, borne on large compound racemes from July to September.

Culture &c. as above.

A. delphinifolium.—A rare alpine species with slender stems, 6-24 in. high,

native of North America. Flowers pale bluish-purple in June.

Culture &c. as above.

A. eminens.—A European species 2–4 ft. high, producing its blue flowers in June on erect or spreading downy stalks.

Culture &c. as above.

A. gracile.—A slender-stemmed Italian species about 2 ft. high, with large pale blue or violet flowers in June.

Culture &c. as above.

A. Halleri.—A straight-stemmed branched plant, 4–6 ft. high, from Switzerland, with dense violet flowers in June. The variety *bicolor* has white flowers variegated with blue.

Culture &c. as above.

A. japonicum.—A beautiful Japanese species 2–6 ft. high, with large, flesh-coloured flowers, produced from July to September. The variety *cæruleum* has deep blue flowers.

Culture &c. as above.

A. Lycoctonum (*True Wolf's Bane*). A native of Europe, with slender upright stems 4–6 ft. high. The rather large creamy yellow flowers are borne on more or less downy and branched racemes about July and August.

Culture &c. as above.

A. Napællus (*Common Monk's Hood*). A very handsome and at the same time virulently poisonous plant, with slightly pubescent stems, 3–4 ft. high. It is found wild in England in shady places near streams, and has black spindle-shaped roots, and 5–7-parted leaves, with narrow pointed segments, the upper ones often sessile; stalks dilated at the base. The dark blue hooded flowers are borne on racemes 1–2 ft. long from July to September.

There are a large number of varieties of this species, differing chiefly in the shades of colour. One with whitish flowers is very interesting.

Culture &c. as above.

A. ochroleucum (*A. Nuttalli*; *A. pallidum*).—A native of Russia, 2–4 ft. high, producing its large cream-coloured flowers about July.

Culture &c. as above.

A. ottonianum.—A plant 2–4 ft. high, from the Carpathian Mountains. The blue

flowers variegated with white appear in July and August.

Culture &c. as above.

A. paniculatum (*A. hebegynum*).—A native of France and Switzerland, 2–3 ft. high. The large violet flowers appear from June to September on a somewhat downy, much-branched, terminal panicle.

Culture &c. as above.

A. pyrenaicum.—A Pyrenean species 2 ft. high, with long-stalked leaves, smooth above, rather hairy beneath, and producing its large yellow flowers in June.

Culture &c. as above.

A. rostratum (*A. alpinum*).—A Swiss plant 1–2 ft. high, with violet flowers produced in June.

Culture &c. as above.

A. rubicundum.—A Siberian perennial about 3 ft. high, with very deep green foliage, and purplish flowers tinged with yellow, produced in July and August. Closely related to *A. vulparia*.

Culture &c. as above.

A. tauricum (*A. plicatum*).—A native of Germany 3–4 ft. high, with dense racemes of deep blue flowers appearing in June.

Culture &c. as above.

A. uncinatum.—A species 4–8 ft. high, from N. America, having branches arising from the axils of the trapeziform, pinnately lobed leaves. The large lilac flowers appear in July, and have a somewhat spiral spur.

Culture &c. as above.

A. variegatum.—A handsome European species 1–6 ft. high, with glistening deeply divided leaves. The large blue flowers appear in July and August, and are variegated with white.

Culture &c. as above.

A. vulparia (*A. lupicidum*).—*Foxbane*. A well-known European plant 1–3 ft. high, with 3–5-lobed, ciliated leaves. The pale yellow flowers are borne on crowded racemes about July.

There are several varieties, among which may be mentioned *carpathicum*, from the Carpathian Mountains, with lurid flowers sometimes variegated with yellow; and *septentrionale*, from Siberia, with reddish-lilac or claret-coloured flowers produced in August and September.

Culture &c. as above.

ACTÆA (BANEERRY; HERB CHRISTOPHER).—A small genus of erect perennial herbs, with alternate, 2-3-ternate leaves, and long erect racemes of small whitish flowers which are succeeded by poisonous berried fruits. Sepals 3-5, almost equal, petal-like, deciduous. Petals 4-10, small, clawed, spoon-shaped, flat. Stamens numerous, longer than the sepals.

Culture and Propagation.—For the ornamentation of moist, half-shady spots of the rockery or flower border, the *Actæas* are very useful. They like a rich, moist, loamy soil with the addition of peat, leaf-mould and sand, the latter being essential to keep the whole light and porous. The plants may be increased by sowing seeds as soon as ripe about the end of July or August, either out of doors in a shaded place, or in cold frames in a compost of sandy peat and loam. The seedlings are pricked out when large enough to handle, and if sturdy they may be planted in their flowering quarters by the end of September or October. It is perhaps better, on the whole, however, to wait until spring.

Actæas may also be increased by dividing the blackish roots in autumn or in spring.

A. alba (*White Baneberry*).—A North American species 12-18 in. high, with ovate-lanceolate, toothed or cut leaves, and simple racemes of white flowers in May and June. Berries white ovoid-oblong on red stalks.

Culture &c. as above.

A. spicata (*Common Baneberry* or *Herb Christopher*).—A native plant about 1 ft. high found on limestone copses. It has a stout black rootstock and leaves 2-3-ternately-pinnate and toothed. The white flowers appear in May, and are replaced by black, oblong, poisonous berries.

The variety *rubra* is a very handsome variety from N. America. It differs from the ordinary Baneberry in having bright red berries in dense clusters overtopping the leaves.

Culture &c. as above.

CIMICIFUGA (BUGWORT; BUG-BANE).—A genus of ornamental herbaceous perennials resembling the Baneberries in habit and foliage. Flowers in racemes somewhat offensive in odour. Sepals 4-5, subequal, petal-like, deciduous. Petals

1-8, small, clawed, 2-lobed, or absent. Carpels 1-8, separate, becoming follicles when ripe.

Culture and Propagation.—These plants are easily grown in ordinary garden soil, preferably in a moist shady place, and may be used in masses. They may be increased by dividing the root in spring, or from seeds sown as soon as ripe in the same way as recommended for *Actæa* above.

C. americana.—A native of Carolina, 2-4 ft. high, with tripinnate leaves, and beautiful feathery panicles of whitish sweet-scented flowers in August and September.

Culture &c. as above.

C. cordifolia.—Also a native of North America, 2-3 ft. high, with biternate leaves, having 4-5-lobed, toothed leaflets, heart-shaped at the base. Flowers in July and August in white racemes.

Culture &c. as above.

C. elata.—This is a fetid-smelling herb about 2 ft. high, native of N. America and Siberia, in which latter country it is used on account of its offensive smell for driving away bugs. The leaves are ternate or biternate, with ovate oblong deeply toothed leaflets, and the paniced racemes of whitish flowers appear in June and July.

Culture &c. as above.

C. foetida.—A beautiful European species 2-3 ft. high, resembling *C. americana* in habit and foliage, and bearing panicles of white flowers in July which are remarkable for their evil smell, as are also the green seed pods.

Culture &c. as above.

C. japonica.—A Japanese species 3 ft. high, with large ternate leaves cut into 5-7 heart-shaped lobes. The white unstalked flowers appear in summer on long spikes.

Culture &c. as above.

C. racemosa (*C. serpentaria*; *Actæa racemosa*).—This is the 'Black Snake-root' of N. America, and grows from 3 to 5 ft. high, with 3-ternate leaves, having serrated or cut leaflets. The white flowers are borne on very long compound racemes in July and August.

Culture &c. as above.

XANTHORHIZA.—A genus with only one species described below:—

X. apiifolia.—A pretty North American bush 2–3 ft. high, with long-stalked pinnate leaves, composed of 3–5 more or less ovate lance-shaped, cut, lobed, and toothed leaflets. The small dark purple and often polygamous flowers are produced in March and April in compound racemes before the leaves have developed. The flowers consist of 5 petal-like sepals, and 5 small clawed petals often broadened at the top.

Culture and Propagation.—This species will thrive in ordinary good garden soil, and may be grown in the shrubbery or border. New plants are chiefly obtained by layering the shoots in summer and autumn, or by detaching the suckers and replanting in early autumn or spring. Seeds are seldom or very rarely produced in this country.

PÆONIA (PÆONY, PEONY, or PIONY). A genus of herbaceous plants with perennial rootstocks, or branched, more or less woody stems. Leaves alternate, large, more or less finely cut or lobed. Flowers beautiful, purple, white, rose &c. Sepals 5, herbaceous, persistent. Petals 5–10, conspicuous, broad, not pitted. Carpels 2–5, surrounded by a fleshy disc; follicles dehiscent; seeds large.

HERBACEOUS PÆONIES

Culture.—Pæonies will grow freely in most soils, but being gross feeders they prefer good moist loam, which previous to planting should be well trenched and have a dressing of rotted cow manure. Plants with 2 or 3 crowns eventually make splendid specimens, and provided a good mulch of manure is placed round the crowns every winter, say in January or February, the plants need not be disturbed for several years and will produce glorious masses of flower each year during May, June, and July, according to locality. The best time for planting is early autumn—say in October—before growth has quite ceased, and late spring, about April, when growth has commenced. The crowns should not be placed deeper than 1–2 in. below the surface, and the clumps not less than 3 or 4 ft. apart. With a view to having fine plants in the future, the bloom-buds should be pinched off the first season after planting, so that all the work of the roots and leaves is devoted to building up a strong healthy specimen.

Pæonies if not 'coddled' thrive in all

sorts of positions, but the flowers last longer in shaded situations, and the foliage is more luxuriant than in spots fully exposed to the sun.

If the flowers are cut just as they are about to open, they will retain their beauty and freshness a long time in water. Mixed with masses of their own foliage, they are excellent for room decoration. If the flowers, however, are cut after expanding, they last only for a short time.

Propagation.—The herbaceous Pæonies are usually increased by carefully dividing the stocks in autumn or spring. Seeds may also be sown as soon as ripe, but they are a very long time in germinating. As, however, it takes from five to eight years to obtain a really good flowering plant from seeds, this method of propagation is rarely adopted, except by large growers who make a speciality of raising novelties. The single-flowered varieties produce seeds in abundance, but the double-flowered ones, which are much more highly valued, only rarely produce seeds. The best time to sow Pæony seeds is when they are thoroughly ripe. Prepared light loamy soil in a cold frame or sheltered border is used, or the seeds may be sown in pots or pans.

P. albiflora (*P. edulis*).—This well-known species is a native of Siberia, where its roots are sometimes eaten by the Mongolian Tartars. It grows 2–3 ft. high, and has leaves at first reddish, then of a ruddy green, smooth, with oblong acute leaflets 3–4 in. long, 1–1½ in. broad. The beautiful white or pink flowers, which are bright red in bud, appear in May and June, sometimes as many as five on a slender stem, and emit a sweet Rose-like fragrance.

The best known varieties are *fragrans*, *sinensis* (*Humei*), *tatarica*, *uni-flora*, *vestalis*, and *Whitleyi*.

Culture &c. as above.

P. anomala (*P. Fischeri*; *P. intermedia*; *P. sibirica*).—It is probable that the typical *P. anomala* is not in cultivation, most of the cultivated forms, according to Mr. Lynch of the Botanic Gardens, Cambridge, being derived from a variety called *insignis*. It is a native of N. Europe, Siberia &c., and has large spindle-shaped roots from which arise stems 2–3 ft. high. Leaves 10–12, cut into numerous confluent lance-shaped acute segments 1½–2 in. long, the lower

leaves having 30-40. The bright crimson solitary flowers, 4 in. across, appear in May and June, the outer sepals being produced into long, often compound, leafy points. The fruits (follicles) are covered with a red or white down.

Culture &c. as above, p. 165.

P. arietina.—A native of S. Europe, 2-3 ft. high, with pale green or blue-green leaves, downy beneath, having more or less oblong or lance-shaped confluent segments. The dark red solitary flowers, about 4 in. across, appear in May, and are replaced by 3 or 4 densely woolly fruits, spreading almost horizontally from the base.

The variety *Andersoni*, which is probably a native of the Levant, has blue or glaucous-green leaves, and deep rose flowers with slightly crisped petals. The variety *cretica*, from the mountains of Crete, is one of the earliest of Pæonies, and may be recognised by its pale glaucous green leaves when springing out of the ground. The flowers are pale rose or nearly white with torn or jagged petals.

Culture &c. as above.

P. Bakeri.—A distinct species, resembling *P. triternata* in habit, and named a few years ago by Mr. Lynch, of Cambridge. It has cylindrical and somewhat spindle-shaped roots, and stout stems about 2 ft. high, reddish, flexuose, and hairy from the lowest leaf to the flower. The red-stalked leaves are biternate, with broadly ovate-acute segments about $3\frac{1}{2}$ in. long, the upper surface tinted with red, the under hairy and glaucous. Flowers deep rose, over 4 in. across, with obovate slightly crisped petals, usually with a white median line beneath.

Culture &c. as above,

P. Barri (*P. Russi*, Bot. Mag. t. 2264). This is another new species created by Mr. Lynch. It has leaf segments about 5 times as long as broad, scarcely downy but very glaucous below, and brilliant red flowers produced in May. The true *P. Russi* is described on p. 167.

Culture &c. as above.

P. Broteri.—A native of Spain and Portugal, and closely related to *P. coralina*. It has cylindrical roots, reddish stems, smooth ovate pointed leaflets, broadest near the middle, and rosy-red or sometimes white flowers, appearing in May and followed by hairy fruits.

Culture &c. as above.

P. Brownei.—A rare North American species about 18 in. high, with pale green or blue-green leaves, having ternately divided or cut leaflets. The globose flowers appear in May and are about 1 in. in diameter, with dull red petals brighter on the edges.

The variety *californica* has bifid or trifid, never pinnatifid, leaflets, the apical segments being oblong, lanceolate, acute, and not glaucous.

Culture &c. as above.

P. corallina (*P. Mas*).—A native of S. Europe to Asia Minor, with spindle-shaped or knobby roots. It has reddish stems 2-3 ft. high, and smooth, deep green leaves with reddish veins, cut into more or less broadly ovate segments. The crimson or rose-red flowers appear in May, having 6-8 obovate or rounded petals 2-3 in. long.

Culture &c. as above.

P. coriacea.—A species from the S. of Spain, mountains of Morocco and Algeria. The leaves are cut into broadly ovate entire smooth leaflets, firm in texture. The flowers are large, bright crimson, appearing in May.

Culture &c. as above.

P. decora.—A Servian species related to *P. arietina*, with smooth stems 2-3 ft. high, and pale green or slightly glaucous leaves, red at the edges, smooth or slightly hairy beneath, cut into numerous oblong blunt leaflets. Flowers in May, solitary, crimson, with 6-8 petals $1\frac{1}{2}$ -2 in. long, and about 1 in. broad. The large hairy fruits are widely divergent.

The variety *Pallasi* has narrowly oblong leaves, while those of *elatior* are broadly oblong.

Culture &c. as above.

P. Emodi.—A fine but rather rare species from the Himalayas. It grows 2-3 ft. high, with thin, smooth, deep green leaves paler beneath, and cut into numerous lance-shaped pointed segments. The white flowers, 3-4 in. across, are produced in March from the axils of the upper leaves, and have unequal obovate petals $1\frac{1}{2}$ -2 in. broad, while some of the outer sepals are produced into leafy points.

Culture &c. as above. This fine Pæony requires a warm sheltered situation and thoroughly well-drained soil so that it does not suffer during the winter months

from stagnant moisture at the dormant roots.

P. humilis.—A well-known garden plant 18–24 in. high, native of the S. of France. The leaves are biternate with red-tinted stalks, and are cut into numerous oblong-acute confluent segments, deep green and smooth above, pale green and downy beneath. The solitary bright red flowers appear in May on short stalks, having roundish petals 2 in. long.

Culture &c. as above.

P. hybrida, which is not a hybrid but a native of the Caucasus, may be regarded as a variety of *P. tenuifolia*. It differs, however, in not having creeping stems, and the leaf segments are somewhat broader. *P. laciniata* is a synonym.

Culture &c. as above.

P. microcarpa.—A species from the Spanish mountains, 12–18 in. high, and closely related to *P. humilis*. The red-stalked leaves are very downy beneath, and cut into numerous oblong-acute segments. The flowers are bright crimson, appearing in May.

Culture &c. as above.

P. mollis.—This is supposed to be a native of the Crimea, and grows about 12 in. high. The rigid hairy stems bear dark bluish-green much-divided leaves, densely hairy beneath. The solitary purple-red flowers appear in May, and are smaller than those of *P. officinalis*. Fruits usually 3, erect, slightly incurved, and densely hairy.

Culture &c. as above.

P. officinalis.—This native of South Europe is the most generally met with Pæony in gardens, especially the double-flowered varieties, which are very beautiful. It is 2–3 ft. high, with smooth deep green leaves, paler and sometimes downy beneath, cut into numerous lance-shaped segments, 1–2 in. broad. The solitary flowers are usually red or crimson, but there are various shades to white, all appearing in May and June.

Among the finest varieties of *P. officinalis* mention may be made of the following: *anemoneiflora plena*, in which the central petals are united into an elevated tuft, the outer petals being similar to those of the single form; *purpurea plena* (also known as *fulgens* and *splendens*) has globular double flowers of a reddish-purple, the central petals being more or less narrowly strap-shaped, and raised some-

what above the outer and much larger petals; *incarnata plena* has beautiful crimson flowers which become white as they grow older; *alba plena* is a fine double white variety, as is also *maxima rosea plena*, and *striata elegans*, with deep rose-striped flowers. *P. lobata* is a dwarf form with narrower and more numerous leaf-segments. It is a native of Portugal, and may be readily recognised by its brilliant salmon-coloured flowers.

Culture &c. as above.

P. paradoxa.—A native of Southern France and Hungary, 12–18 in. high, forming dense tufts of leaves, much cut and lobed, with red margins. The flowers appear in May and June, one on a stem, and are of a purple-red colour.

This is closely related to the next species, but has smaller ovate and more glaucous leaves, with more divided, crowded, and overlapping leaflets. Cultivation, however, has produced a good many modifications of the type, and there now exist forms between the single type and those with very double flowers.

Culture &c. as above.

P. peregrina.—A well-known plant from S. Europe. It grows 1½–2 ft. high, having dull green leaves, smooth above, paler and hairy beneath, and cut into oblong-acute segments, 3–4 in. long, and 1–1½ in. broad. The bright crimson flowers having 5–10 petals appear on short stalks in May and June.

Culture &c. as above.

P. pubens may be regarded as a variety, and is distinguished by its hairy stems and leaves, the latter with red margins, the leaflets tapering to a point, and flowers rosy-red. The variety *byzantina* has biternate leaves of a pale grass-green and stems covered with white hairs. *Compacta* grows only about 1 ft. high, and has very broad, overlapping leaflets with very blunt divisions, and purple-red flowers.

Culture &c. as above.

P. Russi.—A native of Corsica, Sicily, Sardinia and Algeria. It is 12–18 in. high, with spindle-shaped roots. The lower leaves are biternate, thin in texture, and cut into ovate or oblong segments. The bright crimson flowers appear in May and June.

Culture &c. as above.

P. tenuifolia.—A very distinct species 2–18 in. high, with creeping stems,

and a native of Transylvania to the Crimea, Caucasus, and Armenia. The leaves are cut into very numerous linear, one-nerved segments, and at once characterise the plant. The solitary flowers with roundish sepals, and dark crimson elliptic wedge-shaped petals, appear in May and June, and are enhanced in beauty by the golden stamens with purple filaments surrounding the deep purple velvety carpels in the centre.

The handsome double varieties of *P. tenuifolia* are those most usually grown in gardens.

Culture &c. as above.

P. triternata.—A native of the Caucasus, Asia Minor, and the Crimea, 18-24 in. high. The roots are oblong or cylindrical, and the smooth leaves, pale green above, glaucous beneath, are cut into oblong leaflets, bluntly rounded at the apex and with a small cusp. The rose-red flowers are borne in May and June, one on a stem, and have 6-8 obovate petals 2-2½ in. long.

Culture &c. as above.

P. villosa (*P. sessiliflora*).—A species closely related to *P. mollis*, but having longer petioles, and white flowers.

Culture &c. as above.

P. Wittmanniana.—A distinct but somewhat rare species from the Caucasus and N. Persia. It is about 2 ft. high, with biterminate leaves, usually having not more than 3 ovate deep green segments to each division, downy beneath. The flowers are borne on short stalks in April and May, and have roundish sepals and petals, the latter about 2 in. long, and of a pale yellow colour.

Culture &c. as above.

HYBRID PÆONIES.—The Pæony owes its importance as a beautiful garden plant chiefly to the fact that hundreds of first class varieties have been raised in this country and on the Continent by intercrossing a few natural species, chiefly *P. albiflora* and *P. officinalis*, although a few have sprung from *P. peregrina*; two or three from *P. tenuifolia*; what are known as the Chinese Pæonies from *P. Reevsi* and *P. Pottsi*; and the Anemone-flowered kinds which bear traces of *P. officinalis* and *P. paradoxa*.

The following is a list of the best Hybrid Pæonies grown, but as new ones

appear every year, those in search of novelties may consult trade catalogues.

HARDY DOUBLE-FLOWERED CHINESE PÆONIES

Many of the following are very fragrant.

WHITE AND CREAMY YELLOW PÆONIES

Alba plenissima, pure white.

Albion, bluish-white, centre primrose-yellow and white.

Alice Julvecourt, bluish, passing off white, centre tinged primrose.

Candidissima, beautiful primrose-yellow, with pure white guard petals, anemone-flowered.

Comte d'Osmonde, white, tinged bluish, centre bright yellow and beautifully fringed.

Countess of Clancarty, delicate bluish and primrose-yellow, dwarf, erect grower.

Couronne d'Or, large creamy white, laced crimson, showing golden anthers.

Delacour Verhille, pure white, with fine broad petals, strong sturdy habit, flowers of perfect form.

Duchesse de Theba, delicate flesh-white, large broad petals.

Duke of Wellington, yellow, with large pure white guard petals, free bloomer.

Elegans superbissima, pure white, dwarf grower.

Festiva maxima, snow-white, large spreading fully double flower.

Gracchus, primrose-yellow passing off white, very large.

Hélène Leslie, primrose-yellow with large white guard petals.

Lady Dartmouth, beautiful pure white, very large.

Lady Godiva, pure white, centre tinted flesh, full-double, of highest quality.

La Tulipe, large snow-white, laced crimson.

La Vestale, white, with bluish guard petals occasionally laced crimson, fine substance, strong sturdy growth.

Madame Dupont, pure white, laced crimson, full-double.

Marie Lemoine, pure white, with creamy centre, large globular-shaped flower, full-double.

Nitta, fine broad-petalled pure white flowers, a new Japanese variety.

Raiko, a new variety from Japan,

flowers large, pure white, and semi-double.

Snowball (Duchesse de Nemours), large snow-white, tall.

Solfaterre, beautiful primrose-yellow, passing off pure white, tall.

Triomphe de Paris, large broad white guard petals, centre primrose, passing to white, handsome flower.

Viscountess Folkestone, pure white, full-double, of finest form.

Whitleyi, pure white, tinged rose, very early.

BLUSH-PINK PÆONIES

Agnes Barr, softest of pinks, centre canary-yellow and blush, tall grower.

Arethusa, pink, passing to blush, free bloomer, tall grower.

Auguste Mieliez, soft pink, interspersed with yellow, tall grower.

Belle Chatelaine, blush-pink, centre sulphur, changing to white.

Belle Douaissienne, soft rose-pink, centre primrose, passing off pure white.

Caroline Allain, blush-pink, centre flesh to white.

Ceres, soft pink guard petals, with charming fimbriated blush-white centre, pretty.

Charlemagne, blush, laced rose, full double.

Delicatissima, flesh, passing to blush-white, full-double.

Duchess of Sutherland, beautiful pink, tipped silvery-white, dwarf compact habit.

Eugène Verdier, blush, centre white, very large beautifully formed flower, tall grower, free bloomer.

Faust, blush-pink.

Figaro, pink, centre blush, laced crimson.

General Bedeau, blush-white, profuse bloomer.

Grace Darling, soft pink guard petals, centre blush, splashed crimson, petals prettily fimbriated.

Grandiflora carnea, soft flesh, early.

Humei carnea, peach-blossom, centre blush, changing to white.

Lady Ardilaun, delicate blush, centre shaded primrose, fine large flowers.

Lady Somerset, soft rose-pink, laced crimson.

Leonie, blush-white, of perfect form.

Madame Breon, colour an exquisite peach-blossom, large handsome flowers, free bloomer.

Madame de Galhan, beautiful soft pink, enormous flowers of perfect form.

Madame de Vatry, white, guard petals flesh-coloured, fragrant.

Madame Henri, peach-blossom, with prettily tessellated soft yellow centre.

Madame Loise Mère, beautiful blush-pink, large full-double flowers.

Madame Mannoir, beautiful soft pink, fully double, dwarf.

Madame Moreau, pink, with blush-white centre.

Madame Serret, delicate rose, passing to blush.

Madame Vilmorin, blush-white.

Magnifica, soft pink, centre primrose and rose.

Monsieur André, pink, centre shaded flesh.

Monsieur Paillet, soft pink, centre blush, splashed red, very pretty.

Novelty, cream, flushed pink, full-double, very early.

Paganini, primrose, passing off white, with large blush guard petals.

Prince Pierre Galitzin, peach-blossom, primrose centre, prettily fimbriated.

Princess Clotilde, beautiful peach-blossom, with creamy yellow and blush centre, fine form.

Princess May, peach, with creamy yellow and blush centre, tall grower.

Reine des Françaises, silvery-pink, interspersed with yellow, laced crimson, large flower.

Rose d'Amour, lovely blush, full-double.

Saucy Lass, lovely soft rose-pink, centre yellow, very pretty.

Taglioni, pink, centre shaded blush, large showy flowers, profuse bloomer.

The Lady, pink, laced crimson, free bloomer.

Triomphe du Nord, silvery-pink, showing the golden anthers, very pretty, tall grower.

Zoe Verniory, soft pink, centre primrose.

ROSE AND PINK PÆONIES

Alexandre Dumas, bright rose, interspersed with cream, large flower, very free bloomer.

Alice Crousse, beautiful soft rose, flesh centre.

Comte de Paris, rose-carmine, centre stained salmon, passing off blush.

Curiosa, pink, tipped white, tall grower, free bloomer.

Dr. Boisduval, rose, centre salmon.

Dr. Nestor Pelassy, rose-pink.

Globosa, bright pink, centre interlaced with flesh.

Gloire de Patrie, bright rose, tipped white, full-double.

Grandiflora superba, large bright pink guard petals, centre flesh.

Josephine Parmentier, rose, centre pink suffused salmon.

Jules Lebon, rose, full-double.

Lady Carrington, bright pink, tipped white, showing golden anthers.

Lady Leonora Bramwell, beautiful soft rose, very large full-double flowers.

L'Élégante, pink, centre shading to blush, very pretty.

Madame Courant, deep rose, edged silver, fragrant.

Madame Furtado, carmine, centre florets tinted salmon-rose.

Madame James Odier, bright rose, centre passing to blush.

Madonnis, rose, centre pink, large flower of fine form.

Marie Houillon, bright rose, full-double.

Mikado, a lovely new Japanese variety, with large bold guard petals of a beautiful cerise-rose, central florets pink edged gold.

Mons. Galland, bright pink, full-double, late.

Prince Charles, rich cerise-rose, centre tinged salmon.

Reine des Fleurs, bright rose-pink, strongly full-double.

Rose of Castile, bright rose-pink, large full-double anemone-flowered.

Rosea magna, bright rose-pink, centre pink, very effective and showy.

Sidonia, pink, shading to blush, fine large flowers.

Silenus, bright pink, full-double, free bloomer.

Sir Henry Irving, bright rose-pink, very large, of perfect form, a grand late-flowering variety.

Vicomte de Fonceville, clear pink, frilled white.

Washington, beautiful rose-cerise.

FULL DEEP ROSE PÆONIES

Abel de Pujol, full rose, shading to pink, free bloomer.

Adelaide Delache, deep rose, tipped white, profuse bloomer.

Bonaparte, brilliant rose, large loose flower, showy.

Charles Binder, bright carmine.

Charlotte Brontë, bright rose-carmine.

De Candolle, rose-pink, full-double.

Dr. Bretonneau, deep satin-rose.

Étendard du Grand Homme, brilliant rose, very large.

Isabelle Karlitzky, full rose-pink.

John Fraser, a lovely cerise-rose, full-double, of perfect form.

Madame Benard, bright rose.

Madame Lebon, rich cerise-rose, full-double, profuse bloomer.

Modeste Guerin, deep rose.

Nobilissima, rose, finely formed flower.

Sir Charles Dilke, bright rose, tipped blush, showing the golden anthers.

Sir Walter Scott, brilliant rose, shading to pink, showing golden anthers.

Souvenir de l'Exposition Universelle, beautiful rose, passing off pink.

DEEP CRIMSON PÆONIES

Buyckii, intense crimson-purple, dwarf in growth.

Delachei, very deep crimson.

Edward Simmons, large rich crimson, showing the golden anthers, tall grower.

François Ortigat, rich purple, a very richly coloured variety.

Joseph Chamberlain, rich crimson.

Lord Derby, rich purple-crimson, tall.

Lord Salisbury, flowers rich crimson, very large.

Louis Van Houtte, a fine rich purple-crimson, very handsome.

Madame Charpentier, very deep crimson, full-double, dwarf.

Madame Stair, brilliant crimson, tall grower.

Marshal MacMahon, rich full carmine, profuse bloomer.

Paul Risbourg, rich glittering crimson, late-flowering.

Prince Imperial, beautiful bright crimson, tipped purple, fine form.

Prince Prosper, glowing purple carmine, showing golden anthers, very showy.

Reine Potard, very rich glowing crimson.

Robin Hood, rich glittering crimson, showing golden anthers.

Rubra Triomphans, very rich glittering crimson.

Sir Frederick Leighton, rich crimson, tipped white.

Sir William Harcourt, rich glowing crimson, a very bright colour, tall grower.

Superbissimus, rich carmine, tall.

Besides the double-flowered Pæonies there are also many handsome forms with single flowers. Names have been given to several by specialists, but it is better to consult catalogues, as new ones are constantly being added.

TREE PÆONIES

P. lutea.—This is a new and remarkable species from Yunnan, China, and was introduced to Paris in 1887. Being of a woody nature, it now shares with *P. Moutan* the distinction of being a Tree Pæony. It is much dwarfer in growth than *P. Moutan*, and has paler green leaves with much more divided and pointed lobes, the secondary stalks being winged instead of channelled. The yellow flowers appear at the end of May and during June, and seem to be more profusely borne when the plants are grafted than when on their own roots.

Culture and Propagation.—This species is not yet well known, and but little can be said of its behaviour out of doors in cultivation. It is probably hardy in the mild southern and western districts, but would require protection in less favourable parts. The stems may be grafted in the same way as recommended below for *P. Moutan*, and the stocks mentioned there, as well as *P. corallina*, would probably give satisfactory results. This species may also be raised from seeds.

P. Moutan (*Moutan*, or *Tree Pæony*). A fine shrubby much-branched species 3–4 ft. high, native of China and Japan. The smooth leaves are cut into oblong acute segments, and in a young state assume many shades of colour, from purple-crimson to green. The very large and handsome flowers appear in May, and have a wide range of colour, white, rose, salmon, lilac, scarlet, magenta, violet &c. being represented.

Culture and Propagation.—Tree Pæonies like to grow in a good strong, more or less sandy loam, and being very gross feeders, they may with great advantage be given occasional mulchings of well-rotted cow-manure.

The shrubby varieties of the *P. Moutan*

may be increased by cuttings taken in summer with a piece of the older well-ripened stem attached, and inserted singly in small pots with sandy soil, and placed in a cold, shaded frame or greenhouse. They must also be protected from frost in winter. These shrubby varieties are also grafted on the stout fleshy roots of such herbaceous kinds as *P. albiflora* and *P. officinalis*. The grafts are taken late in summer or early autumn, and should be without flower buds. Having united the graft to the root by inserting it in a slit of the latter, and binding the junction, the whole should then be potted and plunged, so as to cover up the graft a little, in ordinary soil, placed in a cold frame, and shaded until the union has become complete. Air may then be admitted, but the plants are best left undisturbed until spring. They may then be grown on in pots or transferred to the open border as required.

In some parts of the country Tree Pæonies suffer more or less from the spring frosts, especially if the previous summer has not been favourable enough to thoroughly ripen the growths. Some of the many varieties are more tender than others, and in such cases a little shelter by means of a glass frame would save the young growths and flowers in spring.

Tree Pæonies are often grown in pots, and are placed in greenhouses so that they may bloom by February. Forcing the plants out of their natural season of flowering, however, exhausts them a good deal, and plants thus treated can be used successfully for such a purpose only about every third year. If grown in pots with very rich soil, and placed in a cold greenhouse or cold frame for protection, Tree Pæonies will flower earlier than those planted out, the blooms will be much cleaner and finer, and the plants will not undergo any severe strain.

The following are among some of the best varieties grown:—

Antigonus, French white and lilac; *caelestis*, soft lilac; *Margaret Attwood*, pure white, with a yellow centre; *The Mikado*, rose and deep yellow; *Luna*, white; *Mammoth*, pink; *Morris*, soft rose; *Jupiter*, salmon; *Duhamel*, lilac-rose; *Mme. Rattier*, cream and flesh colour.

II. CALYCANTHACEÆ—Allspice Order

Shrubs with square stems, and opposite, simple, and scabrous leaves without stipules. Flowers perigynous, axillary, solitary, and often fragrant or aromatic. Sepals and petals numerous, imbricated and combined in a fleshy tube. Stamens numerous, inserted in a fleshy rim at the mouth of the tube, the inner ones being sterile; filaments short. Carpels many, distinct, inserted in a cavity, one-celled, tapering to a filiform style. The fruit is an etærio of indehiscent one-seeded achenes.

CALYCANTHUS (ALLSPICE TREE). A genus of handsome deciduous N. American shrubs, with rather large, purple or livid sweet-scented flowers. They grow in somewhat shaded, moist soil in the warmer parts of the country, but in very cold districts may require a little protection in winter.

Culture and Propagation.—Allspice trees like a rich, well-drained sandy peat and loam, but will grow well in any good garden soil. They are useful for the shrubbery, or in beds by themselves on the grass in warm and sheltered positions, or they may be trained on walls which are overhung and shaded by tall trees. Propagation may be effected by sowing seeds in a cold frame in spring, or as soon as fully ripe. The plants may also be increased by division of the clumps or offsets, and also by layers in summer and autumn, this method being probably the easiest in our climate.

C. floridus (*Carolina Allspice*).—A native of Carolina 4–6 ft. high, with spreading branches and ovate leaves, downy beneath; the wood and roots smelling strongly of camphor. The flowers, which have a sweet apple scent, appear in May. There are several forms of this species which receive distinctive names in catalogues.

Culture &c. as above.

C. glaucus (*C. fertilis*).—This is also from Carolina, and grows about the same height as *C. floridus*. The leaves are ovate and lance-shaped, pointed, glaucous and downy beneath, and the livid purple, not strongly scented flowers appear in May. *C. oblongifolius* is a variety with somewhat elongated leaves.

Culture &c. as above.

C. lævigatus.—A shrub 3–6 ft. high with strictly erect branches, from the

mountains of Pennsylvania. Leaves oblong, thin, blunt or acute, bright green, smooth, or nearly so, paler beneath. Flowers in May, livid purple, like those of *C. glaucus*.

Culture &c. as above.

C. occidentalis (*C. macrophyllus*).—This is the 'Sweet-scented Shrub' of California, and grows 6–12 ft. high, having oblong or ovate heart-shaped pointed leaves, slightly downy on the veins beneath. The brick-red sweet-scented flowers which are 3–4 in. across—each petal being about 2 in. long and $\frac{1}{2}$ in. broad—are produced from June to October.

Culture &c. as above.

CHIMONANTHUS.—A genus closely related to *Calycanthus*, and containing only one species, described below, with the characters of the genus:—

C. fragrans (*Winter Sweet*).—This beautiful hardy shrub is a native of China and Japan, and was at one time also known under the name of *Calycanthus præcox*. It grows 8–10 ft. high or more in the British Islands, and from the middle of December until the end of February and March its leafless twigs are covered with sweet-scented yellow blossoms, each about 1 in. across and with a purple-brown centre. The numerous outer scale-like sepals gradually pass into petals, from which they are scarcely distinct. The stamens are in two rows, the 5 outer ones only being fertile and united at the base, the inner ones being sterile and united into a conelike tube. The leaves appear after flowering is over, and are lance-shaped, tapering in outline, slightly hairy beneath, and rather rough to the touch.

Culture and Propagation.—This charming winter-flowering plant should

be grown in a deep and rich turfy loam, to which a little sand and leaf mould may be added. The soil should be well drained, as stagnant moisture at the root is not only injurious to the growth of the plant, but effectually checks the appearance of its fragrant blossoms just at a period when they are most desirable. During the late summer and autumn months the shoots may be layered, and will be well rooted by the following spring or autumn.

In most parts of the country the 'Winter Sweet' requires the protection of a wall with a south or western aspect.

The shoots may be trained upon it in the same way as those of the Peach and Nectarine. After flowering is over it is essential to thin out all the old and useless shoots, so as to encourage the development of young branches during the year. It is on these young shoots, formed each year after the flowering period, that the blossoms are borne in winter, and it would be a mistake, therefore, to prune the plants in the autumn, when a good deal of such work is done. The variety *grandiflorus* is superior to the type, and has larger flowers.

III. MAGNOLIACEÆ—Magnolia or Lily Tree Order

For the most part beautiful and often aromatic trees and shrubs, with alternate, leathery, entire or toothed leaves, distinctly jointed with the stem. Stipules deciduous, but when young are rolled together, and leave ringed marks where they fall off. Flowers solitary usually hermaphrodite; sepals 3-6, deciduous; petals 3 or more, hypogynous, imbricated in several rows. Stamens numerous, hypogynous, often with dilated or thickened filaments, free, or monadelphous in male flowers. Carpels numerous, rarely few or solitary, spirally arranged upon a torus above the stamens, one-celled. Fruit either woody or fleshy, dehiscent or indehiscent.

This order includes some of the most beautiful flowering trees and shrubs in the world.

DRIMYS.—A genus of fine evergreen half-hardy trees with aromatic bark, and axillary terminal flowers. Sepals 2-3, membranaceous, cohering, deciduous. Petals 6 or more, overlapping in 2 or more rows.

D. aromatica.—A highly aromatic Tasmanian shrub, 9-12 ft. high, with oblong light green dotted leaves, tapering towards the base. The white or pinkish flowers are borne in early summer—the males on one plant, the females on another—and consist of 3 sepals and 6 (or sometimes 8) petals.

Culture &c. as for *D. Winteri*.

D. Winteri (*Wintera aromatica*).—*Winter's Bark.*—A native of S. America, where it reaches a height of 25 ft. or more. It has deep green smooth oblong obtuse leaves, glaucous beneath. The flowers, with 8-12 petals, are about 1 in. across and have a Jasmine-like perfume.

Culture and Propagation.—These two species can be grown out of doors only in the most favourable parts of England

and Ireland. They require the protection of a wall, and their cultivation should not be attempted in cold districts. They thrive in sandy loam, and are propagated by inserting cuttings of the half-ripened wood in a cold frame under a glass during the summer months.

ILLICIUM (ANISEED TREE).—A genus containing only a few species of rather tender smooth evergreen shrubs or small trees, with oblong leathery stalked leaves, which emit an aromatic odour when rubbed between the hands. The yellowish or purple hermaphrodite flowers are borne either singly or in threes on the sides of the twigs. Sepals 3 or 6, membranous, in one or two series. Petals numerous, in many series. Stamen filaments rather thick. Carpels numerous, arranged star-wise on the torus, and becoming fleshy or rather woody when mature.

Culture and Propagation.—The Aniseed Trees require precisely the same cultural treatment as mentioned under

Drimys above. A rich sandy loam, with the addition of a little peat or leaf mould, will suit them all well. They can be grown out of doors with any satisfaction only in the south, and even there they do best in warm sheltered positions. New plants are obtained by placing cuttings of the ripened or half-ripened shoots in sandy soil under handlights during the summer months.

I. floridanum.—This handsome shrub is a native of Florida and other southern parts of the United States. It grows about 8 ft. high, and has oblong lance-shaped leaves somewhat tapering towards the point. The conspicuous deep purple-red flowers, each consisting of 20–30 petals, are produced during the summer months in drooping clusters, and emit a fragrant odour.

Culture &c. as above.

I. religiosum (*I. amiatum*).—This is a native of China and Japan, and grows about 4 ft. high. The branches are clothed with smooth entire leaves, and during the summer months the small yellowish-white flowers are produced in clusters, emitting a sweet odour.

This shrub is held in great reverence by the Japanese, who decorate the tombs of their friends with its branches, and burn the bark as incense.

Culture &c. as above.

MAGNOLIA (LILY TREE).—A genus of beautiful flowering trees and shrubs comprising about 20 species, some evergreen, some deciduous. Flowers conspicuous, solitary, terminal, sessile or shortly stalked, with a spathe-like bract. Petals 6–12 imbricating in 2 or more rows. Carpels numerous, oblong, borne on a more or less conical receptacle. Leaves large entire.

Culture and Propagation.—Magnolias thrive in warm sunny positions in deep rich loamy well-drained soil. When planting, which should be done in the spring just as growth begins, care should be taken to select a spot from which it will not be necessary to remove the plant for at least some years, as too frequent transplanting is detrimental.

The easiest way of increasing Magnolias in this country is by means of layers put down in summer. Seeds, when obtainable, should be sown as soon as ripe in a cold frame, and kept fairly moist until ger-

mination takes place. Cuttings of the half-ripened green shoots with a piece of older wood attached may also be struck under glass during the summer months, and should be grown under protection until well rooted and established before planting out.

Special varieties are increased by grafting them in July and August upon such stocks as the 'Cucumber Tree' (*M. acuminata*) or the 'Umbrella Tree' (*M. Umbrella*).

Some Magnolias are not so hardy as others, and practical experience is the best guide as to whether a species will grow well in a certain locality or not. Very often the spring frosts play havoc with the flowers, although the leaves are left uninjured. The kinds described below are those found most useful in this country. Many of them are useful for cultivation near large towns, as the grime and soot does little harm to the smooth foliage beyond dulling its brilliancy somewhat.

M. acuminata (*Cucumber Tree*).—A N. American vigorous deciduous tree 30–60 ft. high, with oblong acuminate leaves, downy beneath, and 6–12 in. long. The slightly scented glaucous-green flowers, tinted with yellow, are 3–4 in. across, having 6–9 petals, and appear from May to July.

Fine specimens of this tree may be seen in the Royal Gardens, Kew, at Syon House, Claremont &c.

Culture &c. as above.

M. Campbells.—A handsome deciduous tree attaining a height of 150 ft. in its native country—India. Unfortunately it will only grow in the most favoured spots in the British Islands. At Lakeland, near Cork, is a very fine tree 35–40 ft. high, which flowered for the first time in 1883, and again in 1885.

M. Campbells has large oval lance-shaped leaves covered with silky hairs beneath. The slightly fragrant flowers appear in April, and are 6–10 in. across, pale rose inside, crimson outside.

Culture &c. as above.

M. conspicua (*M. Yulan*; *M. precia*). *The Yulan.*—A lovely deciduous Chinese species 20–40 ft. high, with obovate, abruptly pointed leaves, which are downy when young. The large erect white and fragrant flowers, with 6–9 petals suffused with crimson outside, are produced in

great profusion from February to the end of June, the first flowers opening before the development of the leaves.

The variety *Soulangeana* is probably a hybrid between *M. conspicua* and *M. obovata*. Its large white flowers are deeply tinted with reddish-purple. *Soulangeana nigra* is a variety with dark plum-coloured flowers. *Lenné* is also a fine free-flowering variety said to be a hybrid between *obovata* and *conspicua*. There are other forms known as *Alexandrina*, *cyathiformis*, *speciosa*, *spectabilis*, *superba*, *triumphans* &c. scarcely distinguishable. That known as *stricta* is said to be a cross between *Soulangeana* and *obovata*.

Culture &c. as above. The flowers should be protected with canvas or matting in the event of frosty weather.

M. cordata.—A deciduous tree which grows 40–50 ft. high in N. America. Leaves heart-shaped, rather oval, acute, 4–6 in. long, smooth above, woolly beneath. The erect, scentless yellow flowers lined with purple have 6–9 oblong petals, and appear from April to July, and are about 4 in. across. Botanically this is regarded as a variety of *M. acuminata*.

Culture &c. as above.

M. Fraseri (*M. auriculata*).—A fine deciduous tree with spongy wood, native of the Southern United States, where it attains a height of 30–50 ft. The smooth, spoon-shaped leaves are a foot or more long, heart-shaped at the base, with blunt auricles, the under surface being somewhat glaucous. The erect creamy yellowish-white flowers are very sweet-scented, 3–4 in. across, and have 9 oblong petals.

Culture &c. as above.

M. glauca.—A beautiful evergreen shrub from the Eastern United States, where it reaches a height of 15 ft. or more and is known as the Laurel Magnolia or Sweet Bay. The elliptic obtuse leathery leaves are bluish-green above, silvery beneath. The fragrant globular flowers, with 9–12 oval concave petals, are about 3 in. across, and of a creamy-white when first open, changing to pale apricot with age.

The variety *major* (or *thompsoniana*) is a very vigorous form with leaves and flowers much larger than those of the type.

Culture &c. as above. A moist soil

composed of peat and loam suits this species best.

M. grandiflora.—This stately evergreen tree is known as the Laurel Magnolia of the S. United States, where it attains a height of 70–80 ft. In this country there are specimens 50 ft. or more high. The oval, oblong, leathery, deep green, shining leaves with a rusty under surface are characteristic of this species. The erect sweet-scented white flowers 6–8 in. across, with 9–12 petals, are produced freely during July and August on trees which have become well-established.

The Laurel Magnolia is met with in many gardens grown either as a bush tree or trained against a wall with a south aspect, and does equally well in both positions. Cold north and easterly winds are apt to damage the young growths sometimes, and it is therefore desirable to secure a position sheltered from these as much as possible.

Culture &c. as above.

M. hypoleuca.—A fine Japanese tree, 60 ft. high or more in its native country. The leaves are 12 in. or more long, and 6–7 in. broad, deep green, smooth above, covered with white hairs beneath. The deliciously fragrant, creamy white flowers are 6–7 in. across, with a mass of brilliant scarlet stamens in the centre.

Culture &c. as above.

M. Kobus (*M. Thurberei*).—Another Japanese species 70–80 ft. high in a wild state. The leaves are 6–7 in. long, and the creamy white flowers are 4–5 in. across, and appear in May before the leaves. This species has been grown in Kew Gardens for several years.

Culture &c. as above.

M. macrophylla.—A very handsome deciduous tree with smooth white bark. It reaches a height of 30 ft. in N. America. As the name indicates, the beautiful green leaves are very large, 1–3 ft. long, 8–10 in. broad, oblong-obovate, somewhat fiddle-shaped, heart-shaped at the base, the under surface being covered with white hairs. The open bell-shaped sweet-scented flowers, with 6–9 oval petals, appear in June, and are white with a purple blotch at the base, and measure 8–10 in. across.

This species must be considered as tender except in the most favoured spots. It prefers warm soils.

Culture &c. as above.

M. obovata.—A very pretty dwarf deciduous shrub about 5 ft. high, native of China and Japan. It has large obovate dark green leaves, and Tulip-like fragrant flowers, with 6 petals, purple outside, white within, produced in great abundance in April and May.

The variety *discolor* (or *purpurea*) has larger and deeper coloured flowers than the type. There are many other garden forms differing very little from each other, the best being *Borreri*, *angustifolia*, and *erubescens*.

Culture &c. as above.

M. parviflora.—A deciduous Japanese shrub, with roundish-oval, cuspidate leaves, the stalks and principal veins of which are covered with a reddish down beneath. The almost globular white flowers tinted with rose appear about April and May.

Culture &c. as above.

M. stellata (*M. halleana*).—A beautiful dwarf-growing deciduous shrub from Japan, with obovate obtuse or elliptic shortly pointed membranous leaves, 2–5 in. long. The white sweet-scented starry flowers with numerous petals appear from March to May and before the leaves develop.

This is one of the earliest Magnolias to flower, and grown in beds as in Kew Gardens it forms a lovely sight in early spring. It rarely reaches a height of 6 or 7 feet and has a spreading bushy habit.

Culture &c. as above.

M. Umbrella (*M. frondosa*; *M. tripetala*).—This is the Umbrella Tree of the S. United States, and is a free-growing and somewhat straggling deciduous shrub reaching a height of 35–40 ft. in a wild state. Its smooth lance-shaped spreading leaves are 1–2 ft. long, downy underneath when young. In April and May the slightly scented white flowers, 5–8 in. across, with 9–12 petals, are freely produced.

Culture &c. as above.

M. Watsoni.—A beautiful Japanese shrub or low tree, with oblong obovate leaves about 6 in. long, deep green above, paler beneath. The creamy or ivory-white flowers, about 5–6 in. across, are borne at the tips of the young branches in June, and emit a powerful and agreeable fragrance. Each flower consists of 7 or 8 concave or incurved obovate petals,

outside of which is a rosy-pink calyx, and inside which, surrounding the conical pile of carpels, are numerous rows of stamens, having rich crimson filaments and reddish-brown anthers.

Culture &c. as above. This species has been confused with *M. parviflora*, but is quite distinct.

LIROIDENDRON.—As there is only one species in this genus, it is unnecessary to give a separate generic and specific description in this case.

L. tulipifera (*Tulip Tree*; *Whitewood*). A very ornamental flowering tree resembling the Plane in appearance, native of the United States, having a stem sometimes over 100 ft. high and 3 ft. thick, with a greyish-brown cracked bark and many gnarled and easily broken branches. The leaves are roundish, ovate, and three-lobed, the central lobe being obliquely truncate, and forming one of the chief characteristics of the tree. It is only when mature—between 20 and 30 years of age—that the Tulip Tree produces its beautiful Tulip-like flowers of soft green and yellow at the tips of the branches in May. The flowers consist of 3 reflexed sepals, 6 connivent petals, in two imbricated rows, and two-seeded carpels in an oblong spike. There are a few well-marked varieties of the Tulip Tree now in cultivation, the best known being *aureo-maculata*, *integrifolia*, *fastigiata*, and *variegata*.

Culture and Propagation.—The Tulip Tree requires similar soil and treatment to the Magnolias, but is, on the whole, hardier. There are some splendid trees in various parts of the country, and they seem to be quite as happy as the Horse Chestnut. Young trees of various sizes are procurable from nurserymen, but plants may also be raised from seeds sown as soon as ripe in moist sandy loam in warm and sheltered spots out of doors or in cold frames. A rich loamy well-drained soil suits the Tulip Tree best, but any ordinary good garden soil will grow good specimens.

SCHIZANDRA.—A genus containing about half-a-dozen species of trailing or climbing shrubs with membranous, pellucid dotted, exstipulate leaves. Flowers 1-sexed, red, yellow, or whitish, solitary. Sepals and petals 9–12, gradually passing from one to the other. Stamens in the male flowers 5–15, more or less united

into a roundish or ring-like mass. Carpels in the female flowers numerous, becoming indehiscent berries when ripe. Seeds kidney-shaped.

S. chinensis.—A handsome climbing shrub, native of China and Japan, with stems 10–20 ft. long, clothed with simple leaves, and bearing pale rosy flowers during the summer months. After blooming, the berry-like fruits appear and assume a scarlet hue when ripe, remaining on the plant for the greater part of winter.

Culture and Propagation.—This species is the only one fit for outdoor cultivation in the United Kingdom. It requires a warm sheltered position, and must be protected in northern parts during severe winters. A rich sandy loam, with a little peat or leaf soil added, suits it well. Cuttings of the more or less ripened shoots may be rooted during the summer and autumn months under handlights or in greenhouses in the same way as *Drim* and *Illicium*.

KADSURA.—A genus of climbing shrubs closely related to *Schizandra*, but having usually leathery and only rarely membranous leaves. The 1-sexed solitary flowers are borne singly in the axils of the leaves. Sepals and petals 9–15, gradually changing one into the other. Stamens in the male flowers numerous, more or less united. Carpels in the female flowers numerous, capitate, becoming berries when ripe.

K. chinensis.—A rather tender Japanese climbing shrub, with smooth, leathery, more or less oblong-oval leaves, with serrate margins, and tapering at both ends. The white flowers are borne during the summer months on stalks opposite the leaves.

Culture and Propagation.—This plant likes a warm sheltered position and flourishes in southern parts of the kingdom in rich sandy loam, peat and leaf soil. It may be increased by inserting cuttings of the more or less ripened shoots in sandy soil under handlights during the summer months.

IV. ANONACEÆ—Custard Apple Order

An order of trees and shrubs with alternate, entire, exstipulate leaves, and hermaphrodite or rarely 1-sexed flowers. Sepals usually 3, more or less distinct. Petals usually 6, hypogynous. Stamens usually numerous.

Although this order contains about 400 species, mostly natives of the tropics, the following genus is the only one that can be satisfactorily represented out of doors in the British Islands.

ASIMINA.—A small genus of shrubs or small trees, with feather-veined leaves, and nodding short-stalked flowers borne on the sides of the branches. Sepals 3, ovate, valvate. Petals 6, in 2 rows, the inner ones smaller than the outer ones. Stamens numerous. Torus (or receptacle) roundish. Carpels 3–15, becoming an oblong thickened berry when mature.

A. triloba.—A small tree or shrub about 10 ft. high, native of Pennsylvania and other parts of the United States. The leaves are smooth, oblong, wedge-shaped, and the pale purple bell-shaped flowers, about 2 in. across, with a yellow centre, are produced in early summer. The three outer broadly ovate petals are distinctly larger than the three inner ones, and the

points of both series form almost an equilateral triangle.

Culture and Propagation.—This plant is best grown in southern and western parts of the kingdom in warm and sheltered situations, but is fairly hardy in the neighbourhood of London. It likes a rich sandy loam, but will also flourish in well-drained good garden soil. To obtain new plants, the branches may be layered during the summer and autumn months, and severed the following year when well rooted. Imported seeds may also be sown under glass in rich sandy loam, but the young plants should not be placed in the open air permanently until they have attained a good size, and have been well hardened and matured by exposure during the summer months.

V. MENISPERMACEÆ

An order of climbing woody or somewhat herbaceous plants with alternate, exstipulate, usually palmately nerved, entire or palmately lobed leaves. Flowers diceious, small, usually borne in panicles, racemes, or cymes. Sepals usually 6, rarely 9 or 12. Petals usually 6, rarely fewer. Stamens in the male flowers usually equal in number and opposite to the petals, with free or united filaments. Carpels usually 3, rarely 16 or more, free. Fruit drupe-like, sessile or stalked.

COCCULUS.—A small genus of climbing or twining shrubs with ovate or oblong entire or rarely lobed leaves and flowers in cymes or axillary panicles. Sepals, petals, and stamens, 6 of each. Carpels 3. Fruit an obovoid or roundish flattened drupe.

Culture and Propagation.—The two species described below are the only ones grown out of doors in the British Islands, and are fairly hardy in the neighbourhood of London. They will grow in ordinary good and well-drained garden soil, but prefer a mixture of sandy loam, peat and leaf mould. As seeds rarely or never ripen in this country, new plants may be raised by means of cuttings of the young or half-ripened shoots inserted in sandy soil and placed in bottom heat under a bell glass during the spring and summer months.

C. carolinus.—A somewhat downy climber 10-20 ft. long, native of the Southern United States, with entire or sinuate more or less heart-shaped or ovate leaves, and greenish flowers produced in summer in axillary racemes or panicles.

Culture &c. as above.

C. laurifolius.—A compact and ornamental bush 4-8 ft. high, native of the Himalayas, Japan &c. and clothed with smooth shining oblong tapering leaves. The small white or greenish flowers are borne during the summer months.

Culture &c. as above. This species must be sheltered from cold north and east winds.

MENISPERMUM.—A genus of climbing shrubs, with deciduous, rather peltate, palmately lobed or angled leaves, and small greenish-white or yellowish flowers in panicles. Sepals 4-8 in two rows. Petals 6-8, shorter than the sepals. Stamens in the male flowers 12-24, free; in the female flowers 6, sterile. Carpels 2-4, with a dilated stigma. Fruit a more or less flattened drupe.

M. canadense.—A quick-growing Canadian climber with large handsome roundish or kidney-shaped peltate leaves and drooping racemes of small yellowish flowers produced in great abundance in summer.

Culture and Propagation.—This is a good plant for covering walls, trellises, arbours &c., so as to give them an ornamental appearance during the summer months. It likes a rich and rather damp soil and somewhat shaded situations, and may be increased by dividing the root-stocks in spring, or by inserting cuttings of the young shoots in moist sandy soil under glass at the same period. Seeds, which are ripened freely in this country, may also be sown as soon as ripe under glass, afterwards pricking the seedlings out and growing them on until large enough for the outdoor garden.

VI. BERBERIDEÆ—Barberry Order

Shrubs or herbaceous perennial plants, very often spiny. Leaves alternate, simple or often compound, and usually without stipules. Flowers solitary, racemose or paniced. Sepals 2-6, deciduous, in a double row, surrounded with petal-like scales. Petals free, hypogynous, either equal in number to the sepals and opposite to them, or twice as many. ♂ Stamens 4-6

(rarely 8) in two series, opposite the petals, hypogynous, free or sometimes monadelphous in male flowers. Carpel solitary, free, 1-celled. Fruit a capsule or berry.

LARDIZABALA.—A small genus of climbing shrubs with twice or thrice ternate leaves, having entire or sinuate-toothed leaflets. Flowers diœcious, violet or dull purple, borne on axillary peduncles, the male flowers in racemes, the female ones solitary. Sepals 6, fleshy. Petals 6, much smaller. Stamens in the male flowers 6, united in one bundle (monadelphous), and equal in number, but sterile in the female flowers. Carpels 3. Fruit an elongated oblong berry with numerous more or less kidney-shaped seeds.

L. biternata.—A handsome Chilean climber with twice ternate, deep glossy, evergreen leaves, composed of oblong acute leaflets. The small purple flowers appear late in the year but only in very favourable parts of the kingdom.

Culture and Propagation.—This is a useful climber for covering walls, over which it extends its branches often to a length of 20 ft. or more, and covers the surface with its distinct glossy foliage. It is hardy enough on a south wall in the neighbourhood of London, but becomes more luxuriant in growth in more southern and western parts. A compost of rich and light sandy loam and peat, thoroughly well drained, suits it best. New plants may be obtained by inserting cuttings of the more or less ripened shoots during the summer months in light sandy soil under glass.

STAUNTONIA.—A small genus of climbing shrubs having digitate leaves composed of 3–7 leaflets. Flowers monœcious, borne in axillary racemes. Sepals 6, petal-like, the outer ones broader than the inner. Petals none. Stamens in the male flowers 6, united in one bundle (monadelphous), equal in number in the female flowers, but sterile. Carpels 3. Fruit a roundish berry.

S. hexaphylla.—An ornamental evergreen climber, native of China and Japan, with pinnate leaves composed of 6 deep green elliptic ovate-acute leaflets. Its small whitish and sweet-scented flowers are produced in early summer.

Culture and Propagation.—This species is fairly hardy in the neighbourhood of London when grown in sheltered

spots on a south wall. It, however, prefers the more genial climate of the south and west, and may be used in the same way as the *Lardizabala* for covering walls. It thrives in a rich and well-drained sandy loam or any good garden soil, and may be increased by cuttings of the more or less ripened shoots inserted in sandy soil under glass. In autumn any old or useless shoots should be cut away, leaving the younger branches.

HOLBCELLIA.—A small genus of climbing shrubs closely related to *Stauntonia*, and differing from that genus chiefly in the purple or greenish flowers having 6 minute petals instead of none, and 6 free instead of united stamens.

H. latifolia.—This beautiful climbing evergreen is a native of the Himalayas and was once known as *Stauntonia latifolia*, a name under which it is still sometimes better known. Its stems reach a length of about 20 ft. and are covered with deep shining green leaves divided into 3 or 5 oblong leathery leaflets. In favourable parts of the country, the small greenish-purple flowers are produced in axillary clusters in early summer, and are sweetly fragrant. The variety called *angustifolia* is rarely seen, and differs from the type chiefly in having the leaves composed of from 7 to 9 linear lance-shaped leaflets.

Culture and Propagation.—This plant requires to be grown under the same conditions as *Stauntonia hexaphylla* described above. It likes similar soil and situations, and may be increased from cuttings of the ripened or half-ripened shoots in the same way.

AKEBIA.—A small genus of climbing shrubs with digitate leaves composed of 3–5 leaflets. Flowers monœcious, violet, borne in few-flowered axillary racemes. Sepals 3. Petals none. Stamens 6, free in the male flowers; in the female flowers 6–9, sterile. Carpels 3–9, with a peltate stigma. Fruit an oblong - cylindrical berry.

A. quinata.—A pretty climber 6–10 ft. high, native of China and Japan, with digitate leaves composed of 5 oblong

emarginate leaflets. It produces its small violet or purplish sweet-scented flowers in early summer, in drooping racemes.

Culture and Propagation.—This ornamental plant is fairly hardy in sheltered sunny spots near London, but is much more at home in the south and west where the climate is milder. It may be trained on walls, arbours &c., and thrives best in a mixture of well-drained sandy loam, peat, and leaf soil. New plants may be obtained by dividing the roots in spring, or by cuttings of the half-ripened shoots in sandy soil under glass.

BERBERIDOPSIS.—A genus containing only one species described below.

B. corallina.—A handsome evergreen climbing shrub, native of Chili, with alternate, simple, leathery, oblong, heart-shaped leaves about 3 in. long, and furnished with spiny teeth on the margins. The scarlet or crimson-red flowers are borne in axillary clusters on slender drooping stalks during the summer, and look very handsome and brilliant. Each blossom consists of 9–15 sepals and petals scarcely distinguishable from each other, and 8–9 free stamens in the centre.

Culture and Propagation.—This is a fine plant for training on a south wall and is fairly hardy round London. It is, however, more suited for warmer localities. It will grow in ordinary good and well-drained garden soil, but prefers a rich sandy loam. Seeds are produced in good seasons and in favourable localities, and may be sown as soon as ripe or in spring under glass to obtain new plants. The branches may also be layered in the autumn; and cuttings of the young shoots may be inserted in sandy soil in spring.

BERBERIS (including **MAHONIA**).—

BARBERRY.—A genus of about 100 species of erect or straggling yellow-wooded shrubs, with simple or compound leaves, often spiny or reduced to spines. Flowers yellow or orange, racemose or rarely solitary, or fascicled. Sepals 8–9, petal-like. Petals 6, slightly smaller, rarely larger than the sepals, often connivent, imbricated in 2 rows, and often with 2 glands at the base. Stamens 6, free. Carpel 1, with a peltate stigma. Fruit a juicy indehiscent berry.

Culture and Propagation.—Most of the Barberries are easily grown in any garden soil, and in almost any situation.

They, however, prefer a rich and well-drained sandy loam, with the addition of a little peat or leaf mould, in which their roots love to ramble. Many kinds assume brilliant tints in autumn and are very effective at this season if they have been planted in bold masses.

The plants may be increased readily by means of layers and suckers in late summer or autumn. Cuttings of the ripened shoots may also be rooted in sandy soil under handlights or cold frames in autumn. The plants may be transferred to the open ground the following spring in mild showery weather.

Seeds may also be sown as soon as ripe. They must be cleaned from the juicy pulp, and sown thinly in sandy soil, but it is likely they will not sprout till the following spring. When large enough to handle easily the seedlings may be given a little more room in the seed beds, and by the autumn or following spring will be fit for another transplanting.

B. Aquifolium (*Mahonia aquifolia*). *Holly-leaved Barberry.*—A well-known shrubby plant, 3–6 ft. high, from N. America, with Holly-like oddly-pinnate leaves which in a young state are various shades of pale green, brown, and purple. The yellow flowers appear in March and April in nearly erect and much-crowded racemes. Fruits deep purple with a ‘bloom,’ useful for jam making.

Culture &c. as above. This species is probably grown in larger numbers than all the others put together. Young plants are extensively used in autumn and winter for the decoration of window boxes and small gardens. Larger plants are valuable for shrubberies, banks, or, in fact, in any part of the garden where any other plant will not thrive. It stands the drip of overhanging trees well, and is equally happy in the shade or open sunshine. It is a most good-tempered plant, and will grow in the worst of soils. The foliage is largely used by florists, either in its natural state or artificially tinted a deep wine-red.

B. aristata.—This Himalayan Barberry is also known in some places as *B. macrophylla*. It grows 3–6 ft. high, and has more or less oboval, oblong or lance-shaped leaves with four or five spiny teeth, the lower spines being 3-parted. The numerous yellow flowers appear in March and April in drooping clusters and

look very handsome against the smooth green and tender foliage.

Culture &c. as above.

B. buxifolia (*B. dulcis*).—*Box-leaved Barberr*y.—A pretty shrub about 8 ft. high from the Straits of Magellan. Leaves almost sessile, oval or oblong, entire. Flowers solitary on slender stalks. The variety *nana* is dwarfier than the type.

Culture &c. as above.

B. canadensis (*Canadian Barberr*y).—A Canadian shrub 4 ft. high with obovate-oblong distantly toothed leaves, and 3-parted spines. Flowers in many-flowered nodding racemes in spring.

Culture &c. as above.

B. Darwini (*Darwin's Barberr*y).—This beautiful plant is a native of S. Chili, and is perhaps the most popular and pretty of the genus. It forms a dense evergreen bush about 2 ft. high, with oval or oblong leaves about 1 in. long, having usually 5 spiny teeth. The racemes of orange flowers are produced in great profusion in May, and sometimes in the autumn, and are very conspicuous against the dark shining green foliage.

Culture &c. as above.

B. diaphana.—This is a recent introduction from China. It is a strong-growing upright shrub, with pale green leaves and handsome fruits, and also possesses sharp spines about an inch long.

Culture &c. as above.

B. empetrifolia.—A shrub 1½–2 ft. high, from the Straits of Magellan, with linear, sharply pointed leaves, in bundles of about 7. The terminal flowers are borne on slender pedicels in May.

Culture &c. as above.

B. floribunda.—A native of Nepal, about 10 ft. high, with obovate, lance-shaped leaves, tapering much towards the base, having a sharp-pointed tip, and ciliated 3-parted unequal spines. The drooping many-flowered racemes appear in June.

Culture &c. as above.

B. Fortunei.—A pretty evergreen Chinese Barberr y 2–4 ft. high. The pinnate leaves are composed of 3–4 pairs of narrow lance-shaped tapering leaflets about 4 in. long, with spiny serrated edges. They are of a distinct blue-green or glaucous hue. The yellow flowers appear in small compact clusters in spring.

Culture &c. as above.

B. Fremonti.—A handsome evergreen shrub, 3–4 ft. high, native of Texas, Arizona &c. The pinnate leaves are composed of 2–3 pairs of oblong lance-shaped leaflets, each of which is furnished with 2–3 spiny teeth. The yellow flowers appear in March and April in more or less erect loose racemes.

Culture &c. as above.

B. japonica (*Mahonia japonica*).—*Japanese Barberr*y.—A distinct species native of China and Japan. Leaves usually cut into 9 sessile leaflets, about 3 in. long, broadly heart-shaped or rounded at the base, and with about 5 long spiny teeth and a terminal one. Flowers in terminal clusters in spring, lemon-yellow. *B. Beali* and *B. intermedia* are forms of this species.

Culture &c. as above.

B. Lycium.—A handsome Himalayan Barberr y 6–8 ft. high, with whitish stems, and almost persistent and entire leathery leaves, green above and glaucous beneath. The golden-yellow flowers appear late in spring or early summer in drooping clusters, and are succeeded by violet-coloured berries.

Culture &c. as above. This species is quite hardy and is easily recognised even when not in blossom by its narrow entire leaves.

B. nepalensis (*Mahonia nepalensis*).—A distinct and splendid species 4–6 ft. high from Nepal. The leaves are 1–2 ft. long with 5–9 pairs of obovate-oblong cuspidate leaflets rounded at the base, and with 5–10 spiny teeth on each side, and 3 at the apex. The bright yellow flowers appear in March and April in slender elongated racemes.

Culture &c. as above.

B. pruinosa.—A dwarf Chinese shrub, of which the young growths, the under surface of the leaves, and the numerous berries are all pure white, while the flowers are pale creamy yellow.

Culture &c. as above.

B. repens (*Mahonia repens*).—A North American species 1–2 ft. high, having the leaves divided into 2 or 3 pairs of rounded-oval spiny-toothed leaflets, with an odd one at the apex. Flowers in fascicled racemes arising from the scaly buds of spring.

Culture &c. as above.

B. sinensis (*Chinese Barberr*y).—A Chinese plant 3–6 ft. high, with oblong

blunt, entire or slightly toothed leaves; spines 3-parted. Flowers yellow, borne in nodding racemes in May.

Culture &c. as above.

B. stenophylla. — This is supposed to be a hybrid between *B. Darwini* and *B. empetrifolia*, and its narrow abruptly pointed leaves and general habit help to confirm this opinion. It is an excellent plant for massing in groups on the grass, on banks, borders, sides of drives &c., and when bearing its garlands of bright yellow flowers, from February to April, looks really magnificent.

Culture &c. as above.

B. Thunbergi. — A handsome deciduous Japanese shrub with a low-growing spreading habit. The arching stems are furnished with straight spines and clusters of obovate or spoon-shaped leaves $\frac{1}{2}$ -1 in. long, which assume a glowing scarlet hue in autumn. The small drooping flowers appear in April, having red sepals and yellow petals, the latter tinged with red. In autumn they are succeeded by oblong scarlet berries, which with the foliage make this one of the most attractive of Barberries.

Culture &c. as above.

B. vulgaris, the *Common Barberry* of our copses and hedges, is a somewhat acid shrub varying in height from 4-12 ft. It has obovate spiny-toothed leaves, and produces its many-flowered drooping racemes of yellow blossoms in spring. These are succeeded by the orange-red berried fruits which look so handsome in autumn. There is a variety called *atropurpurea* which has rich purple-red leaves and looks particularly handsome in autumn, and many others which differ but little from the type—forty-three being given in the Kew Handlist alone. The variety *asperma* with drooping clusters of scarlet oblong berries is one of the most desirable for shrubberies or fences.

Culture &c. as above.

B. wallichiana. — A handsome Nepalese shrub 6-10 ft. high, with leaves in alternate bundles, 2-3 in. long, lance-shaped, with hollowed and toothed margins. The beautiful globular yellow flowers are borne in drooping clusters in spring for some distance along the slender branches.

Culture &c. as above.

BONGARDIA. — A genus having only one species:—

B. Rauwolfi (*Leontice altaica*). — A pretty little perennial about 6 in. high, native of Central Asia, with a tuberous rootstock from which spring the pinnately cut glaucous leaves with thickish segments again twice or thrice divided or toothed with a purple blotch at the base. The golden-yellow flowers appear in May on branched pyramidal panicles, each blossom being about 1 in. across and drooping from a slender stalklet or pedicel. Sepals 3-6, petaloid. Petals 6, almost similar. Stamens 6, free.

Culture and Propagation. — This plant flourishes in light sandy soil in warm open positions in the rock garden or border. A little peat or leaf mould may be added to the soil, but in winter the rootstocks should be protected from cold heavy rains by a flower pot, bell-glass &c., otherwise the tuberous rootstocks are apt to perish. The plants may be increased by seeds sown in cold frames when ripe, or by offsets taken off in spring, or in early autumn and wintered in a cold frame.

LEONTICE (LION'S LEAF). — A genus with 3 or 4 species of tuberous-rooted herbs and leaves twice or thrice pinnately cut. Flowers yellow, in racemes or panicles. Sepals 6-9 petaloid, the outer ones smallest. Petals 6, much shorter than the sepals, truncate at the apex and nectary-bearing. Stamens 6, free.

Culture and Propagation. — These plants may be grown in the same way as *Bongardia Rauwolfi* in light sandy soil in warm sunny positions in the rockery or border. The tuberous rootstocks or corms should not be buried too deep in the soil, and during the winter months should be protected from cold heavy rains by glasses &c., or they will share the fate of the Bongardias. The plants may be increased by seeds sown in cold frames as soon as ripe, or by means of offsets taken off in early autumn and planted in cold frames until spring; or by detaching them in spring when growth has begun.

L. Alberti. — A native of Turkestan about 1 ft. high, with 5-parted digitate leaves, the lobes of which are bluntly elliptic. The golden-yellow flowers striped outside with red appear in April in conical clusters and look attractive.

Other species met with occasionally are *L. darwasica* from Bokhara, and

L. Leontopetalum, both somewhat resembling the others and requiring the same treatment.

Culture &c. as above.

CAULOPHYLLUM. — A genus having only one species:—

C. thalictroides. — An attractive perennial about 1 ft. high, native of N. America, and resembling both *Bongardia* and *Leontice* in having a tuberous rootstock. The leaves are twice or thrice pinnately cut into narrow pointed segments somewhat resembling the *Thalictrums* (p. 137). The yellow flowers appear in loose racemes or clusters in April, and are succeeded by roundish deep blue berries contracted at the base into a long stalk. Sepals (or bracteoles) 9, the outer ones much smaller, the inner ones petaloid. Petals 6, much smaller, nectary-bearing, dilated and hooded. Stamens 6, free.

Culture and Propagation. — This species thrives in much the same situations as the *Bongardias* and *Leontices*, but prefers a little more peat or leaf mould with the light sandy soil, and also a partially shaded place in the rockery or garden. It may be increased by separating the offsets from the tubers in early autumn and planting in a cold frame; or in spring; and also by sowing seeds if obtainable in cold frames when ripe. The rootstocks should be protected from heavy rains in winter with a sheet of glass or a handlight.

NANDINA. — A genus containing at present only one species described below with the generic characters:—

N. domestica. — A handsome erect evergreen shrub about 5 ft. high, native of China and Japan. The leaves are twice or thrice pinnately cut into entire leaflets, and the small white flowers are produced in summer in panicles at the ends of the shoots or opposite the leaves. Each blossom has numerous sepals and petals, six free stamens and one carpel, the latter eventually becoming an indehiscent berry about the size of a pea when mature.

Culture and Propagation. — This shrub is fairly hardy near London, but it is better adapted for out-door cultivation in southern and western parts of the kingdom. It thrives in ordinary and well-drained good garden soil, but prefers a mixture of good loam, peat, and leaf mould. It may be increased during the summer and

autumn months by inserting cuttings of the more or less ripened shoots in sandy soil under a handlight or in a greenhouse.

VANCOUVERIA. — A genus with only one species:—

V. hexandra. — A graceful and distinct N. American perennial 1–1½ ft. high, with creeping rhizomes and pinnate leaves again twice or thrice divided into slender Fern-like segments. It produces its slender clusters of bluish-coloured flowers in early summer, each blossom consisting of numerous sepals, 6 petals, and 6 free stamens.

Culture and Propagation. — This species flourishes in sandy peat, in moist and shaded parts of the rock garden, and when grown in large masses looks very effective. It may be increased by division in early autumn or spring; or by seeds sown when ripe in cold frames.

EPIMEDIUM (BARRENWORT). — A genus of about 8 species of ornamental herbaceous plants with creeping perennial rhizomes and annual stems. Leaves stalked, compound, with bristly-toothed leaflets. Flowers variously coloured. Sepals 8, petaloid, flat. Petals 4, hooded or spurred. Stamens 4, free. Carpel 1.

Culture and Propagation. — The *Epimediums* are suitable plants for the rock-garden in somewhat shaded positions, and flourish in a compost of peat and loam in about equal proportions. In winter the withered leaves look somewhat untidy, but they serve as a protection for the young buds and should not be removed until the spring, when danger from severe frost has passed. The foliage of many kinds assumes bronzy and ruby tints in autumn.

The plants are usually increased by dividing the roots early in autumn, or better still in spring just as growth is about to commence. At this period cuttings of the roots may also be inserted in sandy peat, and if placed in gentle heat will develop roots more quickly. Seeds may also be sown in pots or pans in spring, or as soon as ripe in cold frames, and may be treated like seedling *Barberies* as above.

E. alpinum. — A plant 6–9 in. high, native of Central Europe, but found naturalised here and there in England on rockworks, old castle gardens &c. Leaves biternate with heart-shaped, oval-pointed,

serrated leaves. Flowers in spring, 12-20 in a loose panicle, outer sepals greyish, inner ones dark crimson; petals yellow, forming a slipper-shaped spur, bearing a fancied resemblance to a bishop's mitre.

Culture &c. as above.

E. diphyllum (*Aceranthus diphyllus*).—This Japanese species is the dwarfiest of the genus, and rarely exceeds 3-4 in. in height. The leaves have stalks 2-3 in. long, with only 2 heart-shaped oval leaflets. The numerous small white drooping flowers appear in April and May, and have spurless petals.

Culture &c. as above.

E. macranthum (*E. grandiflorum*).—A handsome Japanese species 10-15 in. high with biternate leaves about 1 ft. long, cut into 9 heart-shaped oval leaflets 2-3 in. long with closely set hairy teeth. The white flowers appear in late spring and early summer on short racemes, and have the spur of the petals deflexed. *E. violaceum* is a dwarf variety, with smaller violet flowers. There are other forms.

Culture &c. as above.

E. musschianum.—An erect compact-growing species about 1 ft. high, native of Japan. The leaves are ternate or biternate with nine heart-shaped oval leaflets 2-3 in. long. The dull white blossoms appear in May on short, close, simple racemes.

Culture &c. as above.

E. perralderianum.—An Algerian species closely related to *E. pinnatum*. Leaves with 3 heart-shaped oval segments 2-3 in. long, bright green sometimes suffused with brown or dull purple. Flowers bright yellow $\frac{1}{2}$ - $\frac{3}{4}$ in. across, the petals having an erect toothed blade, and an incurved strap-shaped brown spur.

Culture &c. as above.

E. pinnatum.—A handsome, vigorous Persian plant 8-24 in. high, with 3-pinnate leaves 12-18 in. long, having ovate-acute stalked leaflets, toothed on the margins. Flowers in late spring or early summer, bright golden-yellow, in loose racemes 6 in. or so long.

Culture &c. as above.

E. purpureum.—A Japanese species somewhat like *E. alpinum*, but having larger divisions to the leaves. The flowers appear in May, purplish outside, brownish-yellow within, and much larger than those of *E. alpinum*.

Culture &c. as above.

E. rubrum (*E. alpinum rubrum*).—The native country of this species is unknown. The plant is much like *E. alpinum* in habit, but is a more vigorous grower. The leaves vary from biternate to almost ternate, with sometimes as many as 20 leaflets. Flowers over $\frac{3}{4}$ in. across, with oblong deciduous greyish sepals, and inner petals bright crimson, the outer petals being pale yellow tinged with red.

Culture &c. as above.

DIPHYLLEIA.—A genus with only one species:—

D. cymosa (*Umbrella Leaf*).—A pretty N. American and Japanese perennial 12-18 in. high, with horizontal rhizomes, from which spring pairs of large roundish peltate and more or less deeply lobed leaves. The white flowers appear in summer and are borne in large loose clusters, being eventually succeeded by bluish-black berries. Each blossom consists of 6 petaloid sepals; 6 somewhat larger flat petals; and 6 free stamens.

Culture and Propagation.—This interesting plant flourishes in moist peaty soil and is thus suitable for massing in front of Rhododendrons, Azaleas, Kalmias, and other peat-loving plants of the Heath order. Or it may be grown near the margins of lakes &c. in similar soil. It may be increased in spring as growth commences by dividing the rhizomatous roots.

JEFFERSONIA.—A small genus containing only two species of perennial herbaceous plants having radical palm-nerved leaves, mostly 2-lobed or 2-parted. Flowers white, solitary, on a naked scape. Sepals 4, petal-like. Petals 8, flat, larger than the sepals. Stamens 8, free. Carpel 1. Capsule leathery.

J. binata (*J. diphylla*).—A pretty herbaceous plant 3-6 in. high, native of the United States, with leaves deeply 2-lobed, and white flowers, having the above characters, produced in spring.

Culture and Propagation.—This species prefers a rather moist and shady situation in the rockery or flower-border, and will thrive in a soil composed of peat, sand and leaf soil. It may be increased by dividing the rootstocks in early autumn. Seeds may also be sown at the same period, or as soon as ever they are thoroughly ripe. They may be sown out of doors in a prepared bed, and when the

seedlings are large enough to handle may be transplanted to their permanent positions.

PODOPHYLLUM (MAY APPLE; MANDRAKE).—A genus of two species of perennial herbs with creeping rootstocks and thick fibrous roots. Leaves peltate, palmately nerved and lobed, one or two on the stems. Flowers white, solitary, terminal, shortly stalked, nodding. Sepals 6, petal-like. Petals 6–9, flat, larger than the sepals. Stamens as many or twice as many as petals, free. Carpel 1, with a dilated peltate stigma. Fruit an indehiscent berry.

Culture and Propagation. — The Podophyllums thrive in moist, peaty soil in warm, sheltered and somewhat shady spots. They may be increased by seeds sown as soon as ripe in sandy peat, in pots or pans, and sheltered in cold frames. The following spring the seedlings may be given more room to develop, and by autumn or the next spring will probably be fit for placing in the open border or rockery. Plants may also be raised by dividing the rootstock in early autumn or spring, the latter being on the whole the most suitable period.

P. Emodi (*Himalayan May-Apple*). An erect Indian plant 6–12 in. high, with 2 alternate long-stalked leaves 6–10 in. across, 3–5-lobed to the middle or base, lobes wedge-shaped, sharply toothed,

the whole surface being heavily spotted or washed with purple. Flowers in May, less than 2 in. across with very deciduous sepals, and 6 (occasionally 4) obovate oblong petals. Berries red, 1–2 in. long, elliptical, edible.

Culture &c. as above.

P. peltatum (*American Mandrake*).—A North American plant 6–12 in. high, with poisonous leaves and roots. The glossy green wrinkled leaves are 5–9-parted, with oblong, rather wedge-shaped toothed lobes. The flowerless stems end in a large round 7–9-lobed peltate leaf, like an umbrella; the flowering stems have 2 one-sided leaves with the stalk near the inner edge. The waxy-white flowers as large as those of the Christmas Rose appear in May, and have 12–18 stamens in centre. The green crab-like fruits, which are 1–2 in. long, sweet, and slightly acid, edible, ripen in July, and assume a yellowish tinge with age.

Culture &c. as above.

P. pleianthum.—A distinct and very interesting Chinese species 1–2 ft. high, with roundish peltate leaves, divided into 6–8 triangular toothed lobes. The floral leaf stems are forked, and from the axil are produced large bunches of drooping purple flowers, which in due course are succeeded by glaucous-green berries 1–2 in. long, becoming purple when ripe.

Culture &c. as above.

VII. NYMPHÆACEÆ—Water-Lily Order

Herbaceous plants growing in lakes, pools, ponds, ditches, or slow-flowing rivers, at the bottom of which their fleshy rootstocks are embedded in the mud, and their large long-stalked heart-shaped or peltate leaves float on the surface of the water. The usually large, beautiful, and often sweet-scented flowers also either float on the surface or are slightly raised above the water. There are usually 4 sepals, free or rarely adherent. Petals and stamens numerous, sometimes all free and hypogynous, often passing gradually one into another. The ovary is many-celled, with radiating stigmas, and numerous ovules, and is more or less surrounded by a large fleshy disc.

NUPHAR (YELLOW WATER-LILY; BRANDY-BOTTLE).—A small genus with three or four species, natives of the northern temperate hemisphere. The flowers are rather large and yellow, with 5–6 concave, leathery, hypogynous sepals, and numerous small stamen-like petals. Stamens numerous, shorter than the sepals, hypogynous, closely imbricated.

Stigma peltate, rayed. Fruit a berry of separable carpels, ripening above water.

The Brandy-Bottles are lovely water plants, requiring the same conditions as the Water-Lilies proper, which see.

N. advena (*Nymphaea advena*).—A beautiful native of the lakes, ponds, and ditches of N. America from Canada to Carolina. Leaves erect, heart-shaped,

with divaricated lobes, on half-round stalks. The large yellow flowers with red anthers in the centre rise well above the surface of the water in summer, on round stalks. There are 6 sepals, purple within, green outside.

Culture &c. as below.

N. luteum (*Yellow Water-Lily*).—A native of the still waters of Great Britain and Ireland, with roundish, deeply 2-lobed leaves 8-12 in. across. The fragrant yellow flowers appear from June to August slightly above the surface, having 5 sepals, 18-20 obovate wedge-shaped leathery petals, and 10-30 rayed stigmas. The variety *intermedium* has flowers 1½ in. across, with 10-14 rayed stigmas, waved at the margin.

Culture &c. as below.

N. pumilum (*Nymphæa Kalbiana*). This plant is a native of Britain, and is also distributed over Arctic and Central Europe and N. Asia. It is very similar to *N. luteum*, differing in the smaller more rounded petals, and shorter anthers. Stigmas 8-10-rayed, lobed at the margin. The yellow flowers appear from June to August.

Culture &c. as below.

NYMPHÆA (WATER-LILY).—A genus of aquatic plants with large floating deeply heart-shaped or peltate leaves. Flowers showy, solitary, red, white, blue, and intermediate shades. Sepals 4, inserted almost at the base of the torus. Petals numerous and stamens numerous, adnate to the torus, the inner petals being transformed into stamens. Carpels numerous, sunk in the fleshy disc, and with it forming a many-celled ovary, crowned by the connate radiating stigmas. Fruit a spongy berry ripening under water.

Culture and Propagation.—There are altogether between 40 and 50 species of Water-Lilies known, but most of them are too tender for out-door cultivation in the British Islands. Those described below have been found to stand our climate well, and should be grown by all who have a small piece of water at their disposal. They grow better in natural ponds, pools, or quiet streams, but may also be successfully flowered in artificial tanks sunk in the ground to a depth of about 3 ft. The rootstocks are best planted in spring in about a foot of soil beneath the water. To prevent the soil being scattered it is a good plan to

have it in a shallow basket or other receptacle which will readily sink to the bottom. Casks or tubs may also be used, and if sunk level with the surface of the ground the leaves and flowers will in due course make a pretty picture during the summer and autumn months.

Water-Lilies are increased usually by dividing the tuberous rootstocks and re-planting them in spring as described above. The rootstocks may be left in the mud during the winter, or they may be taken up and kept in a cool place in sand until planting time. Seeds may also be sown in autumn as soon as ripe. As the fleshy fruits and seeds ripen under water and are apt to be lost or destroyed by water-fowl or insects &c., care should be taken to secure them in good time, but not before they are thoroughly ripe. The seeds may be sown in pots or pans of loamy soil, and just submerged in water—if possible in a greenhouse where they can be attended to, or if outside, under protection. In spring, when the small round leaves appear and float on the water, each seedling may be placed in a pot by itself and again placed under water, to be grown on until the following spring. If large enough it may then be planted like the older rootstocks in a pot or tub, from which it cannot be easily lost during the dormant period.

For room decoration the blossoms are admirably adapted. If cut just as they are opening and placed in shallow bowls of water with some green foliage, they make a handsome picture. The period of their freshness may be extended by cutting half an inch or so off the end of the stalks, thus allowing a fresh layer of cells to come in contact with the water. The absorptive process goes on for a long time in this way by renewing the cuts, and the flowers retain their plumpness and brilliancy much longer in consequence.

The Queen's Water-Lily, the *Victoria Regia*, which attracts so many thousands to Kew every year, is closely related to the common hardy Water-Lily. It is a native of the Amazon River, and the circular leaves with upturned rims are often 6 ft. or more in diameter. It is raised from seed every year as described above, but the seed pots are placed in water up to 85° Fahr.

N. alba.—This is the common white Water-Lily of Great Britain and Ireland and is a beautiful early summer flowering

plant, and according to locality is often in bloom in May. It has fleshy rootstocks from which arise the roundish, heart-shaped entire leaves 5-10 in. across. The scentless flowers are 4-6 in. across, and float on the surface of the water. The sepals are linear, oblong, green outside. Petals oblong, blunt. There are a few varieties, such as *candidissima*, with broad-petalled flowers; *plenissima*, with an extra number of petals; *maxima*, with larger, and *minor*, with smaller flowers than the type.

Culture &c. as above.

N. candida (*N. semiaptera*).—A Bohemian species like *N. alba* but smaller. Flowers snowy white, 2-3 in. across, sepals tinged with green.

Culture &c. as above.

N. flava.—This is a native of the South United States, and is probably hardy enough for the mildest parts of this country. It has slender rootstocks forming numerous suckers, and oblong rounded leaves, 4-6 in. long, 3-5 in. broad, shallowly crenate, and irregularly blotched with dark brown in the early part of the season. Flowers in summer, canary-yellow.

Unlike other species, *N. flava* is not quite deciduous, and the roots, if taken up, should therefore never be dried off, but be kept in damp soil or wet moss.

Culture &c. as above.

N. nitida.—A native of Siberia with heart-shaped quite entire leaves, on smooth stalks, and without prominent nerves underneath. The white scentless flowers with blunt petals appear in June, and are 3-4 in. across.

Culture &c. as above.

N. odorata.—A beautiful N. American species resembling *N. alba* but quite distinct from it. Leaves heart-shaped, entire, with nerves and veins very prominent on the under surface. The sweet-scented flowers, 6 in. across, appear from June till September, usually white, tinted with rose, and opening in the morning, but closing after midday.

The variety *rosea* or *rosacea* has beautiful flowers suffused with pink; *sulphurea* has prettily marbled leaves and sulphur-yellow flowers 8 in. across; *grandiflora* has yellow sweet-scented flowers, and leaves mottled with brown above, and spotted with red beneath; *exquisita* has flowers of a deep rosy-

carmine almost red at the base of the petals; *superba* is a fine large-flowered form, and *minor* has smaller leaves and flowers than the type; *caroliniana* is said to be a cross between the variety *rosea* and *N. alba candidissima*, and is a grand variety; *gigantea*, as the name implies, has fine large flowers.

Culture &c. as above.

N. pygmæa.—This elegant species from N. Asia is the smallest of the Water-Lilies. Its heart-shaped entire leaves are little more than 3-4 in. across, and the white fragrant flowers, scarcely 2 in. across, with a greenish-yellow torus in the centre, appear from June to September. *Helvola* is a seedling from this species, raised by M. Marliac. It is a beautiful plant with pale straw-yellow flowers, and somewhat oblong leaves blotched with brown above and red beneath.

Culture &c. as above.

N. sphærocarpa.—This is closely related to *N. alba*, but has rose-carmine flowers, produced in abundance in May and June.

Culture &c. as above.

N. tuberosa.—A beautiful species from the N.E. United States. It has a creeping rootstock with oblong tubers, and circular leaves 8-18 in. in diameter, with an entire or wavy margin. The faintly scented flowers are white, 4-7 in. across, and produced in July and August. It is readily increased by dividing the roots.

The variety *rosea* has exquisite pink flowers deliciously fragrant; *Richardsoni*, which is less vigorous than the type, has pure white double flowers standing well above the water.

Culture &c. as above.

HARDY HYBRID WATER-LILIES

Besides the natural species, many beautiful hybrids have been raised during recent years, and have become exceedingly popular owing to their hardiness in our climate, and because of their free-flowering properties. The name of M. Latour Marliac, of Temple-sur-Lot, France, deserves to be recorded as the raiser of most of these beautiful Water-Lilies.

These lovely plants raised by M. Marliac may for the sake of convenience be classed into 2 groups, viz. :—*Marliacea* hybrids and *Laydekeri* hybrids, as follows:—

N. Marliacea albida.—This is the

finest and largest white Water-Lily, the flowers being fragrant and freely produced.

N. M. carnea is very vigorous and free-flowering, with magnificent flowers, flesh-tinted with a delicate blush, and scented like vanilla.

N. M. chromatella is a charming hybrid, with brown mottled leaves when young, and large fragrant flowers of clear yellow, produced from early spring till late autumn.

N. M. flammea, a splendid variety with white and reddish-purple flowers, the outer petals pink, deepening in colour towards the centre.

N. M. ignea has flowers about 5 in. across, with pale olive-green sepals edged with rose behind, and pale rose almost white in front, the closely imbricating petals being of a deep bright rosy-crimson surrounding the vivid orange-red stamens.

N. M. rosea is the choicest of the hardy pink Water-Lilies, with large cup-shaped flowers of an exquisite soft rose tint much deeper than the variety *carnea*.

N. M. rubro-punctata has flowers 4 in. across, with dark olive-green sepals, flushed with rosy-lilac in front, and deep mauve-purple petals delicately dotted with carmine.

The *Laydekeri* group contains :—

N. L. fulgens, a charming variety with dark green outer sepals and crimson-magenta petals.

N. L. fulva has creamy yellow flowers tinted and lined, with bright red, the stamens being golden-yellow, and the leaves blotched with brown above and spotted with red beneath.

N. L. lilacea has lilac-rose flowers scented like Tea Roses, and about 2½ in. across.

N. L. lucida has large soft vermilion flowers, with orange stamens, and large chestnut-spotted leaves.

N. L. purpurata has symmetrical

flowers of a deep rosy-crimson and vivid orange-red stamens.

N. L. rosea, flowers medium-sized, tender pink to carmine. Stamens orange-red.

Other varieties are: *Aurora*, may be called the Chameleon Water-Lily, as its exquisite flowers change in colour from day to day, being at first rose-yellow, then orange-red, ultimately becoming deep red.

N. Blanda is the purest white, with flowers 4–6 in. across, vigorous and free-flowering.

N. Ellsiana is a choice variety with brilliant carmine-purple flowers.

N. Robinsoni is a fine hybrid with deep rose-coloured flowers, deeper towards the centre, dotted with white, and with orange-red stamens.

N. Signometi is a superb variety with delicate creamy yellow flowers tinted with pale rose and carmine.

N. Andreana.—Flowers 5–6 in. above the water, brick-red, shaded with yellow ochre; stem orange, leaf stalks spotted with chestnut, and streaked with red-brown on the back.

N. gloriosa.—A lovely scented flower 7 in. across, very double, bright red, rosy-white at the tips of the lower petals. Stamens rich red.

N. caroliniana nivea.—Flowers pure white, very large and double, very fragrant. Stamens rich yellow. *N. c. perfecta* has salmon-red flowers, very double; petals blunt and perfectly regular.

N. sanguinea.—Flowers rich carmine-amaranth or clear carmine. Stamens orange-red.

As the Hardy Water-Lilies have come into prominence only during the past few years, there is every reason to believe and hope that many fine varieties are still to be raised. Although all the above are really fine forms they are likely to be superseded by others still finer in due course.

VIII. SARRACENIACEÆ—Trumpet Leaf Order

A small natural order of remarkable and curious-looking perennial herbaceous plants, having tufts of radical leaves which are tubular or pitcher-like in form, and surmounted by a lid. The tubular portion corresponds to the stalk of ordinary leaves, but is more or less highly coloured, veined, and netted. The lid-like portion corresponds to the blade of an ordinary leaf, and is usually very beautifully coloured and netted, while on the inner surface are numerous

more or less bristly hairs. These point downwards like so many miniature bayonets, and are supposed to prevent the exit of insects which find their way unimpeded to the bottom of the pitcher. The top of the latter is furnished with a strong rim, and is also provided with downward pointing bristly hairs so that the leaves are veritable death traps to the insects which frequent them for the sugary secretion which is exuded on the inner surface. Sometimes the pitchers become almost or quite filled with the dead and decaying bodies of the insects.

The flowers are few or solitary, and nodding. Sepals 4-5, free, hypogynous. Petals usually 5, free, hypogynous, but absent in the genus *Heliamphora*. Stamens numerous, hypogynous. Ovary free, 3-5-celled. Style simple, with an entire, lobed, or shield-like apex.

SARRACENIA. — This genus is known under such popular names as 'Indian Cup,' 'Pitcher Plant,' 'Side-Saddle Flower,' and 'Trumpet Leaf,' all more or less appropriate. It contains a few species of half-hardy herbaceous perennials with trumpet-like or tubular leaves as described above, and flowers borne singly at the top of a scape. Sepals 5, spreading. Petals 5, united. Ovary 5-lobed, 5-celled. The style is remarkable owing to the fact that it is dilated into a broad peltate 5-angled, umbrella-like disk, with 5 radiating nerves, the tips of which constitute the stigmatic surface where it is necessary to place the pollen for the fertilisation of the ovules and the development of seeds.

Culture and Propagation.—Most *Sarracenia*s unfortunately are too tender to be grown out of doors successfully in the British Islands. The kind mentioned below is the best for this purpose. It enjoys a marshy spot not too much exposed to hot sunshine. A damp peaty soil in the rock garden will suit it admirably, and the addition of *Sphagnum* moss will also be beneficial. It will retain moisture and prevent evaporation

from the soil in summer, if placed around the plants. To allow the soil to become dry is almost fatal to the plants. As they do not grow very quickly it is rather risky to attempt to increase them by division until good-sized clumps have been attained. If seeds can be obtained they may be sown under glass in moist peaty soil as soon as ripe, and the plants may be grown on in pots until they are sufficiently large and sturdy enough for the open air.

S. purpurea (*Huntsman's Cup*). — A beautiful North American species with blood-red horn-like leaves 4-6 in. long, inflated in the middle, contracted at the mouth, and surmounted with an erect kidney-shaped lid, hairy within and netted with purple veins. The purple flowers are borne in early summer, on scapes about a foot high.

There are many other kinds of *Sarracenia*s, but they are all too tender for the open air. A large number of hybrids have been raised, and these surpass in beauty and vigour the natural species. Most of them may be seen in the green-houses in the Royal Gardens, Kew.

Culture &c. as above.

IX. PAPAVERACEÆ—Poppy Order

Smooth and often glaucescent, or hairy annual or perennial herbaceous plants (rarely shrubs), often with a milky juice. Leaves alternate, entire, or lobed and cut without stipules. Flowers regular, usually nodding in bud, and borne singly on long stalks. Sepals 2, or 3, rarely 4, free, imbricate, caducous. Petals 4-6 rarely 8-12, hypogynous, free, in 2 or 3 series imbricated and often crumpled, deciduous. Stamens numerous, hypogynous,

with slender filaments and erect anthers. Ovary 1-celled, or 2-4-celled by prolonged placentas. Stigmas as many as placentas, radiating and sessile. Fruit a pod, dehiscing by pores or valves.

PLATYSTEMON.—A genus containing only one species, viz.:—

P. californicus (*Californian Poppy*). A pretty annual about 1 ft. high, with narrow entire leaves, the lower ones alternate, the floral ones often nearly opposite or ternately verticillate. The yellow flowers are borne on elongated stalks from June to August, and consist of 3 sepals, 6 petals, numerous stamens, and carpels. The variety *leiocarpus* has smooth carpels.

Culture and Propagation.—The seeds of this species may be sown, like those of the annual Poppies, in spring or autumn, in any good garden soil, and the seedlings should be thinned out if too close together.

ROMNEYA (WHITE BUSH POPPY).—A genus containing only one species—*R. Coulteri*, the characters of which of course are those of the genus.

R. Coulteri is branched, smooth, and glaucous, perennial, 2-8 ft. high, with pinnatifid leaves, the linear lanceolate or deltoid segments of which have hairy margins. The large, fragrant, delicate white flowers, often 6 in. across when fully expanded, appear from June to September at the ends of the branches. There are 3 sepals about 1 in. long; 6 petals, broadly obovate, thickened at the base, each about $2\frac{1}{2}$ in. long, and in 2 circles. Stamens numerous in many circles.

Culture and Propagation.—This fine plant is a native of California, and will grow in most parts of the British Islands. It likes a rich and somewhat sandy loam in warm and sheltered situations. During severe winters in most parts of the country north of the Thames it is wise to protect the crowns by means of litter, dry leaves, or ashes, but protection should be given only in case of real necessity, otherwise the young shoots may be too tender and be unable to stand the later spring frosts. The plants like plenty of moisture in summer, and an occasional dose of liquid manure will be very beneficial.

The easiest way to increase *Romneya Coulteri* is by sowing seed in spring either singly in small pots or in pans or boxes

in a cold frame or in gentle heat. When large enough the seedlings may be pricked out into other boxes, and after being established may be hardened off for transplanting out of doors the next or even the following spring after that. Dull showery weather should, if possible, be chosen for this work. Seeds may also be sown as soon as ripe in autumn in sandy soil in cold frames or greenhouses, and the seedlings may be transplanted the following June. Sometimes the seeds remain dormant for several months after sowing.

As the plants often suffer a good deal in transplanting, it is advisable to be very careful in handling the roots, so as not to cause more injury than is necessary. For this reason it is probably the best plan to raise the plants singly in small pots, from which they may be transferred to pots of a larger size and grown on in cold frames until sturdy enough for the open border. They are more easily transferred from pots than from boxes or from the open border. Cuttings of the roots about 2 in. long, inserted in sandy soil, and placed in a hotbed early in the year, will sometimes produce plants, but cuttings of the shoots rarely root, although they keep fresh for a long time.

PAPAVR (POPPY).—A genus of about 14 species of hairy or glaucous annual or perennial herbs with milky juice, and lobed and cut leaves. The nodding showy flowers are red, violet, yellow or white, on elongated stalks. Sepals 2, rarely 3. Petals 4, rarely 6, crumpled. Stamens numerous, hypogynous. Capsule shedding its seeds by pores or valves under the ledge of the rayed and peltate stigma.

Culture and Propagation.—Poppies—both annual and perennial—are very showy plants, and owing to the difference in height, as well as their habit of growth, are suitable for various parts of the flower garden, in the front, back, or centre of beds or borders according to height. Mixed in patches with other plants, Poppies are far more effective by contrast than when grown in large patches by themselves. The annual

kinds are useful for covering up mounds of earth or bare places, upon which little else will flourish. They are easily raised from seeds sown in spring or autumn in the open border where they are to bloom, the seedlings being in due course thinned out. This process of thinning out is adopted chiefly because annual Poppies do not as a rule transplant well, and as the seeds germinate so freely one can afford to dispense with the surplus seedlings. The perennial kinds may also be increased from seeds sown in spring or autumn, or by division in early autumn, so that they will have a chance to become established before winter. But they are often treated as annuals.

P. alpinum.—A beautiful alpine Poppy 3-6 in. high, with smooth or hairy leaves finely cut into acute lobed segments. Flowers in summer, yellow, rose-tinted or white, the sepals being covered with long adpressed hairs. Capsule roundish, prickly.

Culture &c. as above. Raised from seeds annually.

P. croceum.—A Siberian perennial 9-18 in. high, resembling *Meconopsis cambrica* (p. 194) in habit. It has tufts of erect radical leaves, light green above, blue-green beneath, and more or less covered with hairs. The large orange-yellow flowers appear in summer, and have the petals somewhat wavy on the margins. There is a double-flowered form of this species, which latter is now regarded as a variety of *P. nudicaule*.

Culture &c. as above. Increased by seed and division.

P. glaucum (*Tulip Poppy*).—A brilliant annual Poppy 1-2 ft. high, native of the East, with thickish blue-green leaves, oblong in shape and more or less cut into unequally toothed lobes. The showy flowers appear in summer, the two large outer petals being of a deep scarlet red, shaded with orange, while the two smaller inner ones are of a similar hue, but more or less united and forming a cup round the violet-black stamens in the centre.

Culture &c. as above. Raised annually from seed.

P. Hookeri.—An ornamental Indian species, forming a bushy herb 3-4 ft. high, and very much like the Common Corn Poppy in appearance. The flowers appear late in summer, and vary in colour from

pale-rose to crimson-scarlet with a diffused white or blue-black blotch at the base.

Culture &c. as above. Raised from seeds annually.

P. horridum.—A native of Australia and S. Africa, having few-flowered hairy stems, about 2 ft. high, furnished with rigid prickles. The cut leaves are glaucous, with prickles on the nerves and tips, and the pale red flowers with hairy sepals appear in July.

Culture &c. as above. Raised from seeds annually.

P. lævigatum.—An annual Poppy 1-2 ft. high, native of the Caucasus. It has somewhat glaucous pinnately cut leaves, and large bright scarlet flowers, the petals of which have a deep black blotch at the base, and a border of white round the edges.

Culture &c. as above. Raised from seeds annually.

P. lateritium.—An Armenian perennial 1½-2 ft. high, with linear elliptic leaves, cut at the base, and 6-12 in. long. The bright orange flowers, about 2 in. across, appear in early summer, the sepals being covered with long yellow hairs.

Culture &c. as above. Increased by seeds or division.

P. nudicaule (*Iceland Poppy*).—A beautiful alpine perennial 9-18 in. high, native of Siberia, and the northern parts of America. The glaucous pinnate leaves are cut into fine acute lobed segments. The showy flowers with roundish petals and hairy sepals appear in summer, varying in colour from bright orange to yellow and white.

Culture and Propagation.—Although a perennial, the Iceland Poppy is best treated as an annual, and the seed may be sown in autumn or spring, according as the flowers are required early or late the following season. General cultivation as above.

P. orientale (*Oriental Poppy*).—A brilliant Poppy 2-3 ft. high, native of Armenia. It has rough, bristly, hairy stems and leaves, the latter being a foot or more long and pinnately cut. The deep scarlet-crimson flowers, 6-8 in. across, appear from the end of May to July, and have a black or purplish blotch at the base of each petal. The calyx has 3 sepals instead of 2 as in other species. *P. bracteatum* (often referred to as a

species) is really only a variety of the Oriental Poppy. It grows, perhaps, a little taller, and has hairy deeply cut leaves with oblong serrated and deeply incised lobes, and scarlet flowers. There seem to be a good many forms in cultivation, varying between *orientale* and *bracteatum*, and it is probable that they are hybrids between these two. Other forms are *concolor*, the flowers of which have no blotch at the base, and *triumphans*, more dwarf and free-flowering.

Culture &c. as above. Easily raised from seeds sown as soon as ripe or in spring; or by dividing the plants in early autumn or spring. Plants may also be raised by cutting the fleshy roots into pieces an inch or two long, covering them with rich sandy soil, and placing under a handlight or in a greenhouse. This work is best done when the flowers have passed.

P. pavoninum (*Peacock Poppy*).—A native of Central Asia, with rather small leaves, twice pinnately cut. Flowers in summer, scarlet with a black crescent-shaped blotch at the base of each petal.

Culture &c. as above. Raised from seeds annually.

P. persicum (*Persian Poppy*).—A Persian species about 18 in. high, with pinnately cut leaves, having almost undivided often aristate segments, and brick-red flowers which appear in June.

Culture &c. as above, p. 190.

P. pilosum.—A handsome perennial 1-2 ft. high, with stem-clasping oval-oblong pale green leaves having toothed lobes, and hairy on both surfaces. The stems are also hairy and produce in summer many pale lurid scarlet or deep orange flowers, 2 in. across, with a white blotch at the base of each petal. Native of S.E. Europe.

Culture &c. as above. Increased by seeds and division.

P. Rhœas (*Common Corn Poppy*; *Red Weed*).—A native of British cornfields and waste places, varying a good deal in height. The common form has branched hairy stems with once or twice pinnately cut leaves, the ascending lobes of which have a bristle at the tip. The bright scarlet flowers, 3-4 in. across, appear from June to August, and have petals in unequal pairs.

The variety *umbrosum* is a native of the Caucasus, about 2 ft. high, with dazzling scarlet flowers, having a jet black

blotch at the base of each petal, which is sometimes edged with grey.

Many beautiful double-flowered forms of this Poppy are now in cultivation, and are known as Carnation, Picotee, and Ranunculoid-flowered, representing almost every shade of colour except blue and yellow. The French and German Poppies are also forms of this species. 'Shirley Poppies' are beautiful single-flowered variations of the common Corn Poppy, having the most exquisite and diverse shades—chiefly self-coloured, and without any blotch at the base of the petals.

Culture and Propagation.—All the varieties of the Common Corn Poppy may be sown out of doors about the end of March in the spots where they are intended to bloom. The seedlings should be thinned out to about 6-8 in. apart. To make this operation less tedious the seeds in the first place should be sown as thinly as possible.

P. rupifragum atlanticum.—A pretty Poppy 1-2 ft. high, native of Spain and Morocco, with hairy stems and bright green more or less lance-shaped leaves 6-8 in. long, and pinnately divided. The orange, red, or scarlet flowers appear in April and May, and are 2-3 in. across, erect when open but drooping like other species when in bud.

Culture &c. as above.

P. setigerum (*Bristly Poppy*).—A native of Europe and Asia 1-2 ft. high, and closely related to the Opium Poppy, but differs in having the teeth of the hairy leaves ending in a stiff bristle. The violet flowers appear in summer, but there are now many forms and various shades in gardens.

Culture &c. as above. Increased by seeds and division.

P. somniferum (*Opium Poppy*).—A beautiful annual Poppy 3-4 ft. high, widely distributed over Europe, Asia, India, W. Africa, and naturalised in many parts of the British Isles. The broad, oblong, lobed and waved leaves, with a glaucous hue, are heart-shaped at the base and clasp the smooth stems. Flowers in summer, white, rose, lilac, often striped, and usually with a dark blotch at the base of the often fringed petals.

The Pæony-flowered Poppies have been obtained by selection from this species, as has also the 'Danebrog' Poppy.

P. Musselli is a garden strain with double flowers having fringed petals. These double flowers vary a good deal in colour, and may be had in the following shades: lilac, crimson, red, purple, scarlet, rose &c.

There is also a dwarf race of Opium Poppies, which are somewhat shorter in stature and have double flowers. The variety *monstrosum* is extremely curious. Most of the numerous stamens are changed into small carpels arranged round the ordinary capsule in the form of a crown or fringe. This form comes true from seed, but there is nothing particularly handsome in it.

Culture &c. as above. Increased by seeds sown annually.

ARGEMONE (PRICKLY POPPY).—A small genus of handsome branching annuals and perennials, having yellow juice and covered with stiff prickles. Leaves stalkless, usually spotted with white; recesses spiny-toothed. Flowers about 4 in. across, showy white or yellow, terminal. Sepals 2-3 (rarely 4), concave, mucronate. Petals 4-6 (rarely 8). Stamens numerous.

Culture and Propagation.—Prickly Poppies love a warm loamy soil. They may be raised from seeds sown out of doors at the end of March, or earlier in pans placed on a hotbed, afterwards pricking out the seedlings to their flowering quarters.

A. albiflora.—An annual species, native of Georgia, 1 ft. high, with feather-veined, stalkless leaves, and white flowers, with 3 petals, produced in July and August.

Culture &c. as above.

A. grandiflora.—A perennial 2-3 ft. high from Mexico, with sinuate, smooth, glaucous and spiny-toothed leaves. Flowers in summer, large, somewhat resembling those of *Romneya Coulteri* (p. 190), white with yellowish anthers.

Culture &c. as above. Although a true perennial, this species is usually treated as a tender or half-hardy annual. The seeds are best sown in gentle heat so as to have the plants strong enough to flower early. When raised from seeds sown outside in spring, this species does not bloom till late autumn, but will flower early the following summer if protected.

A. hirsuta.—A beautiful Californian

annual about 2 ft. high, with pinnatifid bristly leaves, and pure white flowers 3-5 in. across, borne in September.

Culture &c. as above.

A. mexicana (Devil's Fig).—A Mexican annual 2 ft. high, with hollow-edged spiny leaves blotched with white and very much resembling those of the Milk Thistle (p. 649). The solitary yellow flowers with 4-6 petals appear in June. *A. hispida* from Colorado is similar to *A. mexicana* but is much more hairy and has yellow flowers. *A. platyceras* is also closely related. It has white flowers.

Culture &c. as above. Raised from seeds annually.

A. ochroleuca.—Also a native of Mexico, with prickly stems, and deeply sinuated or pinnatifid glaucous leaves, blotched with white, and having prickly bristles on the nerves. The pale yellow flowers with 6 petals appear in August.

Culture &c. as above. Raised from seeds annually.

MECONOPSIS.—A small genus of charming and pretty perennial, biennial, or rarely annual herbs, with yellow juice, and entire or often lobed or cut leaves. Flowers showy, yellow, purple or blue, on long stalks, nodding in bud. Sepals 2. Petals 4. Stamens numerous.

Culture and Propagation.—These plants will grow in ordinary good garden soil, and are easily raised from seeds sown in spring. If raised in pans or shallow boxes under protection from frost, the seedlings will be strong enough to plant out by the end of April or May, or they may be grown on in pots until the following spring when they will naturally be much finer in growth. When extra strong plants are required for spring planting, the seeds may be sown in cold frames or greenhouses as soon as ripe and the seedlings grown on during the winter. The plants like plenty of water in summer, but should be kept dry in winter, as at that period moisture at the roots is almost sure to kill them.

M. aculeata.—A beautiful biennial about 2 ft. high, native of N.W. India, with long-stalked, oblong, somewhat pinnate leaves, and purple flowers 2 in. across, with numerous yellow stamens in the centre. They appear in summer and look very effective in masses.

Culture &c. as above. Raised from seeds sown as soon as ripe.

M. cambrica (*Welsh Poppy*). — A beautiful native perennial about 1–2 ft. high, with pale green stalked and pinnate leaves, having toothed lobes. The erect pale yellow flowers (drooping in bud) are borne on long stalks from May to August, each one being 2–3 in. across.

Culture &c. as above. The Welsh Poppy grows freely almost anywhere, and is perhaps most suitable for semi-wild places, on old walls, ruins &c. Where it flourishes it may be left to take care of itself, as seedlings will come up naturally and replace the older plants as they die out.

M. heterophylla. — A beautiful Californian annual 12–18 in. high, remarkable for its handsome coppery orange-coloured flowers with a purple-black centre. They are produced freely in June, each blossom being about 1½ in. across, and with a delicious scent somewhat resembling that of Lily of the Valley. The flowers are not nearly so fleeting as those of other plants in this order, as they last a good time in water, especially if cut before they fully expand.

Culture &c. as above.

M. nepalensis. — A lovely free-flowering biennial from the Himalayas. It grows 3–5 ft. high, and has pale golden-yellow nodding flowers, 2–4 in. across.

Culture &c. as above. Raised from seeds sown under glass as soon as ripe. The seedlings are planted out in spring. They like warm sunny spots.

M. quintuplinervia. — A dwarf-growing compact herb 6–12 in. high, native of Manchuria, and but little known yet in British gardens. The long-stalked lance-shaped leaves are all radical and 5-nerved, the green surface being covered with reddish hairs. The violet or purple cup-shaped flowers about 1½ in. across appear in summer on hairy scapes, and have 4 rhomboid ovate petals with numerous stamens in the centre, the inner ones being twice as long as the outer ones.

Culture &c. as above.

M. simplicifolia. — A biennial from Nepal, about 3 ft. high, with tufted lance-shaped slightly toothed leaves, 3–5 in. long, covered with a dense brownish pubescence. The violet-purple flowers, 2–3 in. across, are produced in summer at the ends of unbranched stalks.

Culture &c. as above. To keep up

a supply of this species a stock of plants should be raised from seeds sown under glass as soon as ripe every year. The seedlings are planted out in spring in warm sunny spots and rich moist and gritty soil.

M. Wallichii. — Perhaps the handsomest species of the genus. It is a perennial from the Himalayas, about 4–6 ft. high, with hairy pinnatifid leaves 12–15 in. long. The drooping pale blue flowers, about 2–3 in. across, are borne in June and July on erect pyramidal stems, the upper ones opening as soon as the lower ones begin to wither.

The variety *fusco-purpurea* is an effective and ornamental variety with brownish-purple flowers 2–3 in. across.

Culture &c. as above. Increased by seed and division. Although really a perennial, this fine species should be raised from seeds every year, sown either as soon as ripe in cold frames, or in spring, so that the stock may not die out. Many plants flower the second year from the date of sowing the seeds, but others do not flower for 3 or 4 years after, and then the plants usually die. Hence the necessity for raising fresh plants from seed regularly.

CATHCARTIA. — A genus with only one species, described below:—

C. villosa. — A beautiful biennial or perennial about 1 ft. high, from the Sikkim Himalayas, and somewhat resembling the Welsh Poppy. The stems and vine-shaped leaves are covered with tawny hairs, and yield a yellow juice. The rich yellow flowers are borne on long stalks in June, and have 2 sepals, 4 petals, and many stamens with conspicuous brown anthers.

Culture and Propagation. — The plants thrive in shady damp sheltered spots, and may be increased by seeds which are produced freely. They may be sown as soon as ripe in cold frames, or in spring in gentle heat, so that the plants may be ready for the open border in May.

STYLOPHORUM. — A genus consisting of three or four species of herbs with perennial rootstocks and yellow juice. Lower leaves pinnately cut or absent; upper ones few, alternate, or the floral ones nearly opposite, lobed or cut. Flowers yellow or red, on long stalks, solitary or somewhat fascicled, nodding

in bud. Sepals 2. Petals 4. Stamens many.

Culture and Propagation.—The species described below thrive in ordinary garden soil. They prefer, however, a mixture of moist sandy peat and loam, and a cool half-shaded corner in the rock garden. They may be increased by dividing the roots in early autumn or spring, or from seeds sown out of doors about April or as soon as ripe.

S. diphyllum (*S. ohioense*).—*Celandine Poppy*.—A beautiful species 1 ft. high, from N.W. America, with leaves and flowers like those of the Celandine (*Chelidonium majus*), pale or glaucous beneath, smoothish. Flowers deep yellow, 2 in. across, produced freely in early summer.

Culture &c. as above.

S. japonicum (*Chelidonium japonicum*).—An elegant plant 12–18 in. high, native of Japan and N.E. Asia, with slender stems, and lower leaves long-stalked and pinnately cut. The yellow Poppy-like flowers appear in May.

Culture &c. as above.

EOMECON (CYCLAMEN POPPY).—A genus having only the following species:—

E. chionantha.—A beautiful Chinese perennial about 1 ft. high, with creeping underground roots, and pale green long-stalked and roundish shallowly lobed leaves, about 3 in. across, with a deep notch at the base, and resembling the foliage of some species of Cyclamen. The pure white flowers about 2 in. across appear from May to September; and have a bundle of deep orange stamens in the centre of the 4 roundish oblong petals. Both flower- and leaf-stalks are reddish in colour, and are effective in compact-growing specimens.

Culture and Propagation.—This pretty plant flourishes in rich and well-drained sandy loam with a little peat or leaf mould added for the sake of warmth in winter, and for retaining moisture in summer. It should be grown in warm sunny positions in the rock garden, and if necessary protected with a sheet of glass or a handlight in winter from cold and heavy rains. It may be readily increased by means of the underground creeping roots, which are about as thick as the finger and send up shoots at the tips every spring.

SANGUINARIA (BLOOD ROOT; RED PUCCOON).—A genus with only one species:—

S. canadensis.—This native of North America grows 3–6 in. high and is a distinct and pretty plant, having thick creeping rootstocks with yellow juice, and solitary, rounded, palmately veined leaves. The beautiful white flowers, one on a stem, appear in April and May, and consist of 2 sepals, 8–12 uncrumpled petals in 2 or 3 circles, and many stamens. The variety *grandiflora* has larger flowers than the type.

Culture and Propagation.—The Blood Root prefers a rather moist soil, and thrives under trees and other more or less shaded places. The rootstocks of this plant should not be taken out of the ground and dried off, as they are apt to lose their vitality by so doing.

It is increased by dividing the rootstocks in spring just as growth is about to commence. When broken, they shed a reddish juice, whence the common name of Blood Root. Seeds may also be sown in pots or pans as soon as ripe, or in spring, but it is safer not to prick the seedlings out until the leaves begin to turn yellow and the young rootstocks are going to rest.

BOCCONIA (PLUME POPPY).—A genus of tall glaucous herbs or shrubs having yellow or orange-red juice, lobed leaves, and numerous small flowers in terminal panicles, each branch and branchlet of which is furnished with a bract. Sepals 2. Petals none. Stamens many.

B. cordata (*B. japonica*; *Macleanya yedoënsis*).—A handsome and stately Chinese perennial 5–8 ft. high, with large glaucous deeply veined Fig-like leaves. The small buff or cream-coloured flowers are produced in great abundance during the summer and look like feathery plumes in the distance.

Culture and Propagation.—To see this plant to advantage it should be grown by itself in nooks and corners or in beds on the lawn. It is magnificent when grown in deep rich loam, and long after the flowers have passed, the flat pale brown seed pods look very handsome. When gently agitated by the wind they have a very graceful appearance.

It may be increased by dividing the thickish roots in autumn or spring. Cuttings of the young shoots from the

axils of the leaves may be taken in early summer, or from the suckers which spring up round the base of the plant. The roots cut up into pieces an inch or two long will also produce young plants. They are best placed in boxes of rich sandy loam and covered over about their own diameter and placed in gentle bottom heat early in spring. The plants should be hardened off with as much air and light as possible before transferring to the open ground during dull showery weather. Seeds may also be sown as soon as ripe, preferably in cold frames or in pots or pans under glass, and the seedlings may be pricked out into light rich soil in spring.

B. frutescens is a Mexican species 3-6 ft. high, not hardy enough to stand our winters, but useful for planting out from June to September. It has large handsome sea-green lobed leaves, and masses of greenish flowers. It is best raised from seeds, and must have the protection of a greenhouse in winter.

Culture &c. as above.

B. microcarpa.—A graceful species about 9 ft. high, native of N. China. It resembles *B. cordata* in habit and foliage, and is if anything rather more ornamental and effective, and that is saying a good deal. The feathery plumes of flowers have a bronzy tint that renders it quite distinct from *B. cordata*, and its beauty is still further enhanced when in fruit.

Culture &c. as above for *B. cordata*.

GLAUCIUM (HORNED POPPY).—A genus of 5 or 6 ornamental annual or biennial herbs, with yellow juice, and lobed and dissected leaves. Flowers large, yellow or crimson, on long stalks. Sepals 2. Petals 4. Stamens numerous.

Culture and Propagation.—The Horned Poppies will grow in ordinary good garden soil. They may be propagated by sowing seeds in the open air in April or May, transferring the seedlings, when large enough to handle easily, to their flowering quarters. This must be done carefully, however, as they do not like being moved. On the whole it is better to sow the seeds where the plants are required to bloom. They may be protected with a handlight or a sheet of glass over a bottomless box until sturdy enough. If sown too thickly the seedlings may afterwards be thinned out.

G. corniculatum (*G. phaenicum*).—A species from the Mediterranean region,

also found naturalised in England. It is about 9 in. high, with oblong, cut, hairy leaves and crimson flowers which appear in summer and have a black spot at the base of each petal.

Culture &c. as above.

G. flavum (*G. luteum*).—A native of Britain, W. Asia and N. Africa, 1-2 ft. high, glaucous throughout, with lower leaves hairy and deeply cut, and with a beautiful silvery sheen. The large bright yellow flowers 2-4 in. across appear from June to October, the petals in opposite dissimilar pairs, and are succeeded by a smooth curved pod about a foot long. The individual blossoms do not last long, but they are produced in great abundance, a certain number opening each day.

Culture &c. as above.

G. leptopodum.—A tufted Chinese species of recent introduction. It has divided leaves and bears yellow flowers in summer.

Culture &c. as above.

CHELIDONIUM (CELANDINE; SWALLOW WORT).—A genus of erect branched herbs with yellow juice, dissected leaves, and yellow flowers. Sepals 2; petals 4; stamens numerous.

C. majus.—This is an erect branched perennial herb, native of Britain and W. Asia. Its stems reach a height of 1-2 ft., being brittle, sparingly hairy, and containing a yellow juice. The thin cut leaves are coarsely toothed, smooth beneath. The yellow flowers, about an inch across, are borne from May to August on slender stems, and have 2 sepals, 4 petals, and numerous stamens.

The variety *laciniata* has the leaves cut into linear acute lobes, the petals being also more or less cut. There is a double-flowered form.

Culture and Propagation.—The Celandine grows freely in almost any soil, but prefers moist shady places. It is a beautiful plant for the wild garden, shrubberies &c., and is easily raised from seeds sown when ripe in the open border or in spring. The roots may also be divided in autumn or spring.

DENDROMECON (TREE POPPY).—A genus with only one species at present known:—

D. rigidum.—A smooth ornamental shrub about 3 ft. high, native of the Californian mountains, with an erect and bushy habit. The more or less ovate

lance-shaped stiffish leaves are $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long and of a conspicuous blue-green or glaucous colour. The golden-yellow flowers, nearly 2 in. across, appear in June, the 4 roundish petals being in striking contrast to the numerous deep orange-yellow stamens in the centre.

Culture and Propagation.—This plant flourishes in a warm and sheltered position in the rock garden or ordinary flower border, and likes a rather rich and well-drained sandy loam and a little leaf soil. It may be increased by cuttings of the non-flowering shoots inserted in cold frames in sandy soil in late summer. If seeds are ripened they should be sown in cold frames at once, and the young plants may be ready in spring for the open air.

HUNNEMANNIA.—A genus containing only one species. It is closely related to *Eschscholtzia*, and similar in appearance and blossom. Sepals 2. Petals 4. Stamens numerous. Stigma lobes 4, short, blunt, spreading or deflexed. Capsule linear 10-ribbed.

H. fumariæfolia.—A graceful and beautiful perennial herb about 2 ft. high, native of California and Mexico. The leaves are deeply divided like those of *Eschscholtzia*, and have a conspicuous bluish or grey-green hue. The solitary brilliant yellow cup-shaped flowers are about $2\frac{1}{2}$ in. across, and appear in August and September, the colouring of the wavy petals being enhanced by the cluster of bright orange-red stamens in the centre.

Culture and Propagation.—This beautiful plant is too tender to be treated as a perennial in the British Islands except in the south and west. It likes a warm sunny position in the flower border and is best raised annually from seeds which are produced freely. The seeds should be sown as soon as ripe in a cold frame or in shallow boxes in a cool greenhouse, but they will not sprout before the following spring. When large enough to handle they may be pricked out into light rich soil, and by the end of May or beginning of June may be planted in bold masses in the flower border.

ESCHSCHOLTZIA (CALIFORNIAN POPPY).—A genus of smooth, glaucescent, ornamental annual or perennial herbs with leaves much cut and divided into linear lobes. Flowers yellow on long stalks. Sepals cohering, forming a deciduous cap. Petals 4. Stamens many.

Culture and Propagation.—The *Eschscholtzias* are easily grown in any soil, and are useful for giving a brilliant effect to borders and shrubberies from early summer to the end of autumn. Seeds may be sown in either autumn or spring in the open border in spots where the plants are required to bloom.

There are some 4 or 5 species all natives of N.W. America, but *E. californica* and its varieties are the only ones usually grown.

E. californica.—A perennial 12-18 in. high, with glaucous finely divided leaves, and large bright orange-yellow flowers which appear in early summer. A host of garden forms have originated from this species, their flowers being white, pinkish, or pale yellow. The variety called *crocea* is a showy biennial about 1 ft. high, having deep rich orange flowers in the type. The garden forms have white, red, and striped flowers; also a double-flowered orange form. The form known as 'Mandarin' is curiously pretty.

Culture &c. as above.

E. cucullata.—A remarkable Californian species, the young leaves of which are strongly incurved or cupped. The flowers are lemon-yellow with an orange centre, but seeds are rarely produced even in a wild state. This species is probably not yet in cultivation.

Culture &c. as above.

E. Douglasi.—A Californian plant of recent introduction with flowers intermediate in size between those of *E. californica* and *E. tenuifolia*. They are bright golden-yellow with a deeper yellow or orange centre, and open a week or two earlier than those of *E. californica*.

Culture &c. as above.

E. tenuifolia is a compact-growing annual about 6 in. high, with leaves divided into threadlike segments. Flowers about 1 in. across, yellow.

Culture &c. as above.

X. FUMARIACEÆ—Fumitory Order

Annual or perennial herbs with brittle stems and a watery juice. Leaves usually alternate, much-divided, often with tendrils. Flowers irregular, purple, white or yellow. Sepals 2, small, scale-like, deciduous. Petals 4, in two usually dissimilar pairs. Stamens 4 distinct (in British species 6), hypogynous, in 2 bundles (diadelphous) opposite the 2 outer petals, one of which is usually furnished with a spur, rarely all separate. Fruit either an indehiscent 1- or 2-seeded nut, or a 2-valved or succulent indehiscent many-seeded capsule.

The irregular flowers chiefly distinguish the Fumitory Order from the Poppy Order.

HYPECOUM. — A small genus of glaucous annual herbs with leaves much cut into linear segments. Flowers white or yellow, with 2 small narrow sepals, and 4 spreading petals, the outer ones flat or slightly concave at the base. Stamens 4, opposite the petals.

H. procumbens. — A native of South Europe, about 1 ft. high, with finely cut glaucous leaves, and bright yellow flowers in summer.

Culture and Propagation. — This species will grow in any good garden soil, and may be raised from seeds sown in the open in spring, for flowering in summer, or in autumn for earlier flowering the following year.

DICENTRA (DIELYTRA; DICLYTRA).
LYRE FLOWER; BLEEDING HEART. — A genus of very ornamental, erect, diffuse, or climbing perennial herbs, with tuberous, horizontal, or fibrous roots, and much-cut, stalked leaves. Flowers in terminal racemes, rose, pink, or yellow. Sepals 2, scale-like. Petals 4, connivent, the 2 outer ones concave, saccate, or spurred at the base. Stamens 6, in two bundles opposite the outer petals.

Culture and Propagation. — The Dicentras thrive in a rich loamy soil, and are lovely plants for the border. They may be increased by dividing the root-stocks in early autumn or spring. Indeed this is the usual method of propagation. Cuttings may also be made of the fleshy roots, placed in sand and kept in a cold frame. Seeds may be sown as soon as ripe, or in spring in light sandy soil in cold frames. The young plants require to be pricked out and grown on until large

enough for transferring to the open border in autumn or spring.

D. canadensis. — A North American species about 6 in. high, with glaucous finely cut leaves. The white flowers appear in May, having 2 short blunt spurs.

Culture &c. as above.

D. chrysantha. — A Californian plant with rather stiff stems 3-5 ft. high, and very finely cut glaucous foliage. The long erect branching racemes of bright yellow flowers appear in August and September.

Culture &c. as above. This species may be raised from seed, and should be planted in a warm sheltered spot. In cold localities it is desirable to cover the roots in severe winters with a little bracken or dry leaves &c.

D. Cucullaria (Dutchman's Breeches).
A curious and not particularly beautiful dwarf species 3-6 in. high, native of the United States. It has smooth, slender, 3-ternate leaves, and produces its white, yellow-tipped flowers having 2 straight spurs in spring.

Culture &c. as above.

D. eximia (Fumaria eximia). — This beautiful perennial grows wild in the rocky clefts of the mountains of Virginia and N. Carolina. It is about 9-18 in. high, with divided leaves, and has compound racemes of drooping reddish-purple flowers in spring and summer and sometimes also in autumn.

Culture &c. as above.

D. formosa (Fumaria formosa). — A North American species, about 6 in. high,

very similar to *D. eximia*, but smaller in all its parts. The bright red broadly ovate flowers appear in May and have short and very obtuse spurs.

Culture &c. as above.

D. spectabilis (*Chinaman's Breeches*). This beautiful and popular plant is a native of Siberia and Japan, and has now become well known in gardens. It is 1-2 ft. high, with stalked leaves cut into obovate wedge-shaped segments. The drooping rosy crimson flowers, about 1 in. long, are freely produced in spring and summer on gracefully arching racemes, and are more or less like inverted lyres in shape. There is a white-flowered variety which is not so effective.

This species is slightly forced in greenhouses in many thousands every year from rootstocks imported in the early autumn. As an outdoor plant there are few perennials to surpass it in the flower border, margins of shrubberies, or rough rockeries, especially if planted in rich loamy soil.

Culture &c. as above.

D. thalictrifolia (*D. scandens*).—A pretty glaucous species native of the Sikkim Himalayas, with slender creeping branches and leaves very much divided and cut as in the Meadow Rues (*Thalictrum*) into oval, oblong, or roundish leaflets. The sweet-scented yellow irregular flowers tinged with red in the throat are produced in late summer and autumn in clusters from the axils of the leaves, on long slender stalks.

Culture &c. as above.

ADLUMIA.—This genus consists only of the species here described:—

A. cirrhosa (*Corydalis fungosa*).—An interesting N. American plant with climbing stems about 15 ft. long. The pale green leaves are thrice pinnate, and resemble the fronds of Maidenhair Ferns. The pale rose or purple coloured flowers, about $\frac{1}{2}$ in. long, appear in June on axillary peduncles, and consist of 2 scale-like sepals, 4 cohering petals, gibbous at the base, and 6 stamens in 2 cohering bundles opposite the outer lobes of the corolla.

Culture and Propagation.—This pretty plant is a biennial, but in warm favourable spots will be reproduced annually from self-sown seeds. Its frail climbing stems and Fern-like foliage make it a useful plant for trailing against a wall

or over shrubs, old branches &c. Seeds may be sown in the ordinary way in light sandy soil as soon as ripe, and the seedlings after being pricked out must be sheltered in cold frames during the winter months. In spring they may be planted out in mild showery weather.

CORYDALIS.—A genus containing about 70 species of pretty, smooth, usually glaucous herbs, with tuberous or tufted rootstocks, and diffuse or slender stems sometimes climbing by tendrils. The leaves are much divided, alternate or almost opposite. The flowers are red, white, or yellow in terminal or leaf-opposed racemes. Sepals 2, often scale-like. Petals 4, the two outer ones larger, one or both gibbous or spurred, often cohering in two usually dissimilar pairs. Stamens 6, in 2 cohering bundles opposite the outer petals.

Culture and Propagation.—Of the many species of Fumitory comparatively few are worth growing in gardens, those described below being the best. They grow easily in ordinary garden soil, and some will thrive in shady spots in damp soil. They make charming groups in the rockery or the front of the flower border and are effective either in foliage or flower. The plants may be increased by dividing the roots after flowering or by offsets from the bulbous-rooted sorts. The annual species of course must be raised from seeds sown out of doors in early autumn or in spring each year.

C. bracteata.—A Siberian perennial about 9 in. high, with biternate leaves cut into linear-lobed segments. The sulphur-yellow flowers appear in May and June.

Culture &c. as above. Increased by division in spring.

C. cava (*C. tuberosa*).—A European perennial, 6 in. high, with biternate leaves cut into wedge-shaped segments. The white flowers are produced from February to May in loose terminal racemes.

Culture &c. as above.—Increased by division of the tuberous rootstocks in early autumn so that the plants will be established for flowering at the proper period in spring. Seeds are not produced very freely, and besides, they often do not sprout for a year or so after being sown.

C. glauca.—A graceful Canadian annual or biennial 9-12 in. high, with

leaves twice pinnately cut into blunt oblong lobes, light green above, blue-green beneath. The scarlet flowers shaded with orange, and having violet sepals, are produced freely from June to September, and in conjunction with the feathery character of the foliage, produce a very ornamental effect in the rockery or flower border.

Culture &c. as above. Increased by seeds sown as soon as ripe.

C. Gortschakowi.—A glaucous green perennial 1–1½ ft. high, native of Turkestan. The leaves are twice pinnately divided or cut, the lower ones being 5–6 in. long. The golden-yellow flowers appear in summer, and are borne in close racemes.

Culture &c. as above.

C. kolpakowskiana.—A tuberous-rooted perennial from Turkestan, 6 in. high, with smooth deeply divided leaves, and long-spurred pink or purple flowers borne in summer in loose racemes.

Culture &c. as above.

C. ledebouriana.—A pretty herbaceous perennial about 1 ft. high, native of the Altai mountains. It has tuberous rootstocks and leaves twice ternately cut into obovate glaucous segments. The purple flowers appear in summer, and have rather a thick pale purple spur.

Culture &c. as above.

C. lutea (*Fumaria lutea*).—A well-known European perennial, about 1 ft. high, now naturalised on old walls in many parts of Great Britain. The pale green biternate leaves are cut into obovate wedge-shaped trifid segments, forming graceful masses. The yellow spurred flowers appear in early summer in great abundance, and continue to be produced well into September. Nestling among the foliage, which retains its freshness almost the whole year, they look very beautiful, and make the plant useful for the decoration of rockeries, ruins, old walls &c. In such places the seeds often sow themselves, and may be left to follow nature's course.

Closely related to this species is *C. ochroleuca*, which has a similar appearance, and is distinguished chiefly by its whitish-yellow flowers, which continue to appear from spring until the end of autumn.

Culture &c. as above. Increased by seeds or division.

C. Marschalliana.—A perennial 9 in.

high, native of Tauria. Leaves biternate with oval entire or bifid lobes, and sulphur-yellow flowers produced in April and May.

Culture &c. as above.

C. nobilis.—A lovely Siberian perennial 9 in. or so high. Leaves twice pinnate, with wedge-shaped segments cut at the apex. Flowers in May, pale yellow, tipped with green, and having a long blunt spur incurved at the point.

Culture &c. as above. Best increased in early spring by dividing the rootstocks.

C. pallida.—A juicy herb 1–1½ ft. high, native of China and Japan. The pale green leaves are thrice pinnately cut or divided, and are blue-green on the under surface. The bright yellow flowers tipped with brown appear in summer and are borne in racemes at the ends of the shoots.

Culture &c. as above.

C. Sewerowii.—A pretty species 12–18 in. high, native of Turkestan, with very finely divided glaucous green leaves, and deep yellow flowers in April and May. Spur short, saccate, and bent downwards.

Culture &c. as above.

C. solida (*C. bulbosa*).—A tuberous perennial, 6 in. high, native of Europe, and naturalised in woods and dampish places in Britain. The very glaucous biternate leaves are cut into oblong or wedge-shaped segments, cut at the top, and the large purplish flowers about 1 in. long are produced in April and May.

Culture &c. the same as for *C. cava* above.

SARCOCAPNOS.—A small genus of dwarf-tufted glaucous perennial herbs, with dissected leaves, the lobes of which are usually broad and rather thick. Flowers white, yellow, purple, or red, in few-flowered terminal racemes. Sepals 2, scale-like. Petals 4, connivent, one of the two outer ones spurred at the base, the other flat, the inner ones narrow and cohering at the apex, keeled or winged behind. Stamens 6, in 2 cohering bundles opposite the outer petals.

S. enneaphylla.—A native of S. Europe, 2–6 in. high, with slender stems and thrice ternately parted and much-lobed leaves on slender stalks. The small yellow flowers marked with purple appear in June.

Culture and Propagation.—This species thrives in ordinary soil, and is suitable for borders or rockeries. Easily

increased by seeds or division of the roots in the same way as *Corydalis* (see above). Cuttings of the shoots may also be made to root under handlights or cold frames during the summer months if inserted in light sandy soil, and kept shaded and fairly damp at first.

FUMARIA (FUMITORY).—A genus of about 40 species of annual (rarely perennial) herbs usually branched, often climbing. Leaves much divided, with very narrow segments. Racemes terminal or opposite the leaves. Sepals 2, scale-like. Petals 4, erect, conniving, the lower one gibbous or spurred at the base, the upper flat, the

two inner ones narrow, cohering at the tip, winged or keeled behind. Stamens 6, in 2 bundles opposite the 2 outer petals.

F. capreolata.—This is the only species worth growing. It is indigenous to the fields and waste places of Britain, Europe, and Asia, and may be grown in the wild gardens or border. It grows about 4 ft. high and has bipinnate glaucous leaves climbing by twisted stalks, and racemes of white, purple-tinted flowers from May to September. There are several forms.

Culture &c. as recommended above for *Corydalis*. Seeds may be sown in autumn or spring.

XI. CRUCIFERÆ—Wallflower Order

Annual, biennial, or perennial herbaceous plants, rarely undershrubs. Flowers hermaphrodite, regular, usually yellow or white, occasionally purple, generally in racemes, and without bracts. Sepals 4, deciduous, imbricate or valvate in bud, the 2 lateral ones often saccate at the base. Petals 4, placed crosswise, and alternate with the sepals. Stamens 6 (tetradynamous), of which 2 are shorter and opposite the lateral sepals, hypogynous. Disk with various green glands opposite the sepals, and between the petals, stamens, and ovary. Ovary superior, one-celled, but apparently two-celled, owing to the parietal placenta meeting in the middle, and forming a spurious dissepiment. Fruit a long (siliqua) or short (silicula) 2-celled and 2-valved capsule or pod, opening by two valves, leaving the seeds on the persistent placentas (known as a *replum*, well seen in *Honesty*), or indehiscent.

MATTHIOLA (Stock).—An important genus of about 30 species of branching annual, biennial, or perennial herbs, or sub-shrubs, with oblong or linear, entire or sinuate downy leaves. Flowers in racemes, often purple, generally sweet-scented. Sepals erect, the lateral ones saccate at the base. Petals with long claws. Fruit-pod a roundish or compressed siliqua, with the lobes of the stigma connivent, thickened or horned at the back. The various garden Stocks, such as Ten Week, Intermediate, Brompton, or Queen Stocks &c., will be considered under the natural species from which they have been derived.

The plant known as 'Virginian Stock' is described under *Malcolmia maritima* (see p. 214).

M. annua.—The Ten Week and Intermediate Stocks have arisen from this species. It is an annual 1-2 ft. high, native of S. Europe, with erect, branching stems,

furnished with lance-shaped, blunt hoary leaves. The flowers appear from May to October on erect racemes, and vary a good deal in size and colour.

TEN WEEK STOCKS

There are many kinds of Ten Week Stock mentioned in catalogues, and they are all more or less worth growing. For cut flowers, Ten Week Stocks are most useful from early summer to autumn, and cutting the main flower spikes often induces the development of the side shoots, which would otherwise remain latent.

Culture and Propagation.—During March the seed may be sown thinly in shallow pans or boxes placed on a gentle hotbed. In a short time the seedlings will be sufficiently large to handle easily. They may then be pricked out into similar pans or boxes, filled with rich loamy soil and well drained. Give

the plants as much light and air as possible, to make them hard and sturdy. By the end of May or beginning of June, when all danger of frost is past, the plants may be placed where they are to bloom. The richer the soil, the better the plants will bloom and the more brilliant the colours, which are white, lemon, pink, rose, scarlet, purple, crimson, violet, with numerous shades of each. If there is no convenience for raising Ten Week Stocks under glass, the seeds may be sown in the open border about the end of April. Plants raised in this way, however, must not be transplanted, as the season in most parts of the country is scarcely extended enough to permit of full development. The seedlings are best thinned out, leaving the most promising plants to flower where the seed has been sown. Among the kinds grown may be mentioned the Dwarf, Large-flowered, Giant, Wall-flower, Victoria, and Pyramidal Ten Week Stocks in various colours.

In order to obtain dwarf, sturdy, bushy plants the leading shoot may be pinched out as soon as the flower-buds begin to swell. By this means growth will be retarded in the main shoot, but will be accelerated in the side ones, each of which becomes longer and bears numerous blossoms.

Seeds may be saved, but only from the single-flowering varieties. But as a rule seed saved in most parts of the United Kingdom is of little use, and it is much better to raise plants from the best imported seeds. To secure a large percentage of double-flowered varieties, it is, however, better to obtain well-ripened and imported seeds from a nurseryman.

INTERMEDIATE STOCKS

These are also derived from the Common Stock, *Matthiola annua*, and are chiefly confined to scarlet, white, and purple varieties. They are very useful for flowering in spring before the ordinary Ten Week Stocks. To secure them at this season, the seeds should be sown in July and August; the seedlings will thus have plenty of time to become well established and hardened to stand the winter. Where glass protection is available, the plants may be grown one or more in a pot, wintered in a cold frame or greenhouse, with as much light and air as possible, when they will make fine bushy plants for early spring flowering.

EAST LOTHIAN STOCKS

This is a form of the Intermediate variety of *Matthiola annua* and is chiefly valuable for producing its flowers in the autumn, after most of the Ten Week Stocks are finished. The seeds may be sown about the end of March or April, and when large enough transplanted in the usual way. By using the Intermediate, Ten Week, and East Lothian Stocks in rotation as named, it is possible to have Stocks in bloom for the greater part of the year.

M. bicornis.—This is a branched sub-shrub, native of Greece, and somewhat tender in the least favourable parts of the country. It has oblong lance-shaped cut leaves, the upper ones being entire. The flowers are purplish-red like those of the Wallflower-leaved Stock (*M. incana*), but smaller, and nearly sessile, with oblong spoon-shaped petals, appearing in spring.

Culture &c. as for the Brompton Stocks below (see *M. incana*).

M. fenestralis.—A sub-shrub about 1 ft. high, native of Crete. It has erect simple stems with crowded, obovate, downy leaves, and scarlet or pale purple flowers produced in July and August, on a long erect raceme, sometimes slightly branched at the base. Only comparatively few double-flowered varieties are obtained from seeds.

Culture &c. as for the Brompton Stocks below.

M. incana (*Wallflower-leaved Stock*; *Brompton* and *Queen Stock*).—This grows in a wild state in W. Europe, the Canaries, the Levant &c., to a height of 1 or 2 ft., having branched sub-shrubby stems with erect, hoary, oblong, lance-shaped leaves, and flowers 1-2 in. across in summer varying from purple to violet.

Culture &c. as below.

BROMPTON STOCKS

These are vigorous growing biennials with handsome flowers of purple, scarlet, white, or crimson. They are not quite hardy in all parts of the British Islands, and where there is a likelihood of the plants suffering during the winter, they should be planted under the protecting branches of trees and shrubs, which will shield them a good deal from the effects of frost.

Culture and Propagation.—Brompton

Stocks are biennial and therefore require two seasons' growth to come to perfection. The seeds may be sown in pans or boxes in June or July. When the seedlings are an inch or so high, they may be transferred to a piece of freshly dug ground and planted 8-12 in. apart. Should the plants be inclined to make a too vigorous and sappy growth, they should be lifted and again transplanted. This will check the growth, and help to harden the plants for the coming winter. This second transplanting often saves the plants from being killed outright in severe winters.

In the north and naturally cold localities it is on the whole safer to winter Brompton Stocks in cold frames, and have them transplanted in spring. If grown in pots they may with advantage be brought into blossom earlier by placing in the gentle heat of a greenhouse.

In the south of England and Ireland Brompton Stocks, if raised from seed sown in spring in gentle heat, will in warm and favourable seasons flower the same year. Some forty or fifty years ago Brompton Stocks were cultivated extensively in the market gardens around London, but for many years past they have disappeared altogether from this region. In the south and in the Channel Islands, however, they are still grown very largely, and from the latter place some fine trusses of bloom are sent to the London markets every year.

QUEEN STOCKS

These Stocks are supposed to be identical with Brompton Stocks and may receive the same treatment. It is said, however, that the seeds are darker than those of the Brompton Stock, and that its leaves are rough and woolly on the under side, while those of the Brompton are smooth on both sides.

WALLFLOWER-LEAVED STOCK

This is a variety of the biennial kind, readily distinguished by having smooth bright shiny green leaves like Wallflowers instead of dull-coloured downy ones like the other Stocks. It may be treated like the Brompton or Queen Stock referred to above.

M. tricuspidata.—An annual about 1 ft. high, from the shores of the Mediterranean. It has oblong, toothed or sinuate

leaves, the upper ones being more divided or cut. The bright lilac flowers, lighter towards the base, appear in summer, and the entire plant is more or less pubescent.

Culture &c. as for Ten Week Stocks above, p. 201.

M. tristis (*Hesperis tristis*).—*Night-scented Stock*.—An interesting biennial from E. Europe, 9-24 in. high. Lower leaves stalked, upper ones ovate, acute, stalkless, entire or toothed, smooth or downy, pale green, 2-4 in. long. Flowers in spring and summer, varying from a dull white to a dull dark purple, usually fragrant in the evening, and scenting the atmosphere for many yards round.

Culture and Propagation.—This sweet-scented Stock flourishes in moist but well-drained garden soil of a loamy nature. It is raised from seeds sown out of doors as soon as ripe, or in the early spring under glass or in gentle heat. In the latter case the seedlings will flower the same year in favourable parts; but autumn-sown seedlings are pricked out and transferred so as to flower the following year. Imported seeds may also be sown as recommended for the Wallflower below.

PARRYA.—A genus of low, smooth or hairy herbs, with perennial roots, and linear or spoon-shaped, entire or sinuate-toothed leaves. Flowers white, rose, or purple, with erect sepals, and clawed spoon-shaped petals.

Culture and Propagation.—Parryas are suitable for the rockery or edge of borders. They grow easily in ordinary garden soil and may be increased by dividing the roots in early autumn or spring. Seeds may also be sown as soon as ripe in the open border, and the seedlings should be transplanted not later than the end of September, so that the roots may obtain a good hold of the soil before winter.

P. arabidiflora.—A Siberian plant 6 in. high with somewhat fleshy lance-shaped leaves and purple flowers in May.

Culture &c. as above.

P. arctica.—A native of Arctic America about 3 in. high, with almost entire leaves and corymbs of pale purple flowers in May and June.

Culture &c. as above.

P. integerrima.—A Siberian plant 6 in. high, with entire, somewhat spoon-shaped

leaves, and beautiful purple flowers in April and May.

Culture &c. as above.

P. nudicaulis. — A pretty little rock plant from the Arctic regions. Leaves elliptic oblong, acute, entire or toothed, 2-3 in. long. Flowers in April and May, 1 in. across, with obcordate petals.

Culture &c. as above.

CHEIRANTHUS (WALLFLOWER).—

A genus of biennial or perennial herbs or undershrubs with oblong or linear, entire or toothed leaves. Flowers rather large, racemose, without bracts, yellow or purple, having erect sepals, the latter ones saccate at the base, and long-clawed petals. The long seed pods are more or less 4-angled, or winged, or compressed.

C. asper (*C. capitatus*).—A somewhat tender Californian species with linear lance-shaped more or less toothed or entire leaves, tapering towards the base and covered with close-pressed hairs. The rather large yellow flowers appear in dense corymbs in June.

Culture and Propagation.—This species requires a rich loamy soil and warm sheltered positions. It may be increased in summer by cuttings of the young and non-flowering side-shoots, which should be put under a hand glass and kept in a cold frame or greenhouse during the winter. Seeds may also be sown when ripe in cold frames, and the seedlings are safer protected in severe winters. In spring they may be planted out.

C. Cheiri (*Common Wallflower*). — A well-known sub-shrubby plant distributed over Central and N. Europe, and reaching a height of 1 or 2 ft. The smooth or slightly hairy leaves are 2-3 in. long, lance-shaped, quite entire, on more or less angled stems. The fragrant flowers are about 1 in. across, and orange-yellow in a wild state, but various shades of red, purple or brown in cultivated forms.

The Wallflower is a beautiful old garden plant, and gives a peculiar charm to old walls, ruins, and semi-wild places, on which it grows freely, and looks far more picturesque than when grown in rows like Carrots or Turnips.

There are many kinds grown and all are very beautiful. Among the single-flowered kinds may be mentioned the 'Blood-red,' 'Harbinger,' 'Belvoir Castle'

'Golden Tom Thumb,' 'Ruby Gem,' 'Eastern Queen' &c. The double varieties are also beautiful, with many shades of yellow, pale and dull brown.

Culture and Propagation.—The seeds of Wallflowers are usually sown too late in the year, the consequence often being that the plants are not sufficiently hardy to withstand a severe winter, especially when hard frosts succeed cold rains. Imported seeds of both single and double kinds are usually better than any saved in the British Islands, as our capricious seasons often interfere with the proper ripening of seeds.

From March to the end of May is the best time for sowing so as to obtain a succession of bloom. The seedlings should always be transplanted to check the tap-root and cause the development of fibrous roots near the surface. By May or June the plants should be in their permanent quarters to give a splendid display of bloom from Christmas to March.

The common custom among cottagers of filling gardens in spring with plants already almost in bloom is not to be recommended, as the plants are too far advanced to do any good, and very often are little better than scarecrows. If spring planting is adopted, it should be done as early as possible in mild open weather, so that the plants will make a brave show until the time for summer bedding out commences, that is, any time from the end of May to the end of June, according to season and locality.

C. Marshalli. — This is a supposed hybrid Wallflower 12-18 in. high, having the lower leaves more or less spoon-shaped, and the upper ones lance-shaped. The deep clear orange-yellow flowers about 1 in. across are freely produced in spring.

Culture and Propagation.— Sometimes this Wallflower does not seed freely, and it must then be increased by means of cuttings of the young shoots inserted in light sandy soil in spring and summer under glass, or in cold frames, much in the same way as recommended for *C. asper*.

C. Menziesi. — A Californian plant 6-8 in. high, somewhat tender, with oblong lance-shaped downy leaves 2-4 in. long, and bright purple flowers.

Culture and Propagation.—Requires the same treatment as *C. asper* above.

C. mutabilis.—A tender shrubby species 2–3 ft. high, native of Madeira. Leaves somewhat downy, linear lance-shaped, finely toothed. Flowers appear in early spring, cream-coloured at first, becoming purple or striped with age.

Culture &c. the same as *C. asper* above.

C. scoparius.—A half-hardy shrubby species from Teneriffe, 2–3 ft. high, linear lance-shaped entire and somewhat downy pointed leaves. The flowers appear in May, at first white, changing to purple.

Culture &c. the same as for *C. asper* above.

C. semperflorens.—A half-hardy shrubby plant 1–2 ft. high, from Morocco. The entire roughish leaves are linear lance-shaped and the yellow and white flowers appear at various seasons.

Culture and Propagation.—The perennial Wallflowers must be kept dry in winter and in sheltered places. They may be increased from cuttings taken in August or September, and during those months inserted in a shady place or in boxes of sandy soil. Also by seeds as for *C. asper*.

BARBAREA (WINTER OR AMERICAN CRESS).—A genus consisting of about 20 species of smooth, fibrous-rooted biennials or perennials, with angled stems. Flowers yellow on erect terminal racemes, sometimes with bracts.

Culture and Propagation.—These plants grow in any soil, and are readily increased by cuttings, suckers, seeds, or division of the roots. The variety mentioned below having double flowers rarely or never produces seeds. It must therefore be increased by dividing the roots in early autumn or in spring, or by inserting cuttings of the side and basal shoots in sandy soil in a cold frame, or a shady border in the summer.

B. vulgaris flore pleno (*Double Yellow Rocket*).—This is the only variety worth growing on account of its bright yellow double flowers which appear from June till the autumn. The lower leaves are cut like those of a Dandelion, the upper ones being obovate, toothed or pinnatifid.

There is a form with yellowish variegated foliage, which may be reproduced from seeds, or by the other methods mentioned above. It makes a good edging plant, and is also suitable for the rockery.

B. præcox, a British plant, is sometimes grown as a salad, the lower leaves being used in the same way as Water Cress and also for seasoning and garnishing.

ARABIS (WALL CRESS; ROCK CRESS).—A genus of 60 or more species of smooth or hairy annual or perennial herbs, the lower leaves of which are stalked and spoon-shaped, the upper ones stalkless, entire or toothed, rarely lobed. Flowers mostly white, rarely purple or rose.

Culture and Propagation.—These plants grow in dry spots, and are very suitable for the rockery or mixed border, where their masses of snowy white flowers render them conspicuous in spring. They are increased from seeds sown in the open border in April and May, or as soon as ripe. The seedlings are pricked out when large enough, and may be transferred to the places where they are to flower either about the end of September or in spring. Seedlings often come up spontaneously where a plant is flourishing. Cuttings of the perennial species placed in a shady border in summer will also root freely, and the young plants thus raised may be transplanted in autumn. As soon as flowering is over the plants may also be divided and re-planted in good garden soil, care being taken to water the plants well after moving.

The following are some of the best kinds for the flower garden, but there are several others met with occasionally in botanical collections.

A. albidia (*A. caucasica*).—A plant 6–9 in. high, native of Tauria and the Caucasus. Leaves few, toothed, hoary or downy, the lower ones obovate oblong, the upper ones cordately sagittate clasping the stem. The white flowers appear in masses from January to May. The variety *variegata* has variegated leaves, and is much used for edgings.

Culture &c. as above.

A. alpina.—A European plant 6 in. high, with many-toothed lance-shaped acute hairy leaves, the lower ones stalked, the upper heart-shaped, stem-clasping. Flowers white, March to May. A double-flowered form has recently appeared. It has no stamens or pistil, but the petals are 12 instead of 4 in number. There is a variegated form having leaves bordered

with yellowish-white, that render it attractive as an edging plant.

Culture &c. as above.

A. androsacea.—A pretty, dense-growing species, about 2 in. high, from Mt. Taurus in Asia Minor, at an elevation of 7000 or 8000 ft. The lower leaves are linear-oblong or lanceolate obtuse in compact rosettes; the upper ones stalkless, linear or linear-ovate, slightly toothed. Flowers in summer, white with ovate petals.

Culture &c. as above for *A. albida*.

A. arenosa.—A native of Central Europe, 6 in. high, with branched hairy stems. Leaves hairy, the lower ones pinnatifid, the upper ones deeply toothed. Flowers from April to July, rose, rarely white or purple, slightly fragrant.

Culture and Propagation.—This species being a biennial or annual is best raised from seeds annually. They should be sown as soon as ripe out of doors, or in bleak parts of the country in cold frames. The seedlings are pricked out in light soil about 1 ft. apart each way, about the end of September. If wintered in frames the plants should have plenty of light and air on all possible occasions, and may be planted out at the first favourable opportunity in spring.

A. blepharophylla.—A Californian species 3-4 in. high, with lower leaves spoon-shaped, upper ones oblong, sessile, all being edged with stiff hairs. Flowers rosy-purple, varying a good deal.

Culture &c. as for *A. albida*. Best raised from seeds annually, as it is often killed in winter.

A. lucida.—A pretty rock plant native of Hungary, 4-6 in. high, with shining, obovate, thickish leaves, clasping the stem. The white flowers appear in summer.

The variety *variegata* is a superior plant with light green yellow-edged leaves. It is a very beautiful rock plant and is very effective in bold masses in rocks or crevices. The flowers detract from the appearance of the foliage, and should be picked off.

Culture &c. as for *A. albida*.

A. mollis.—A native of the Caucasus, 2 ft. high, with large-toothed somewhat downy leaves, the lower ones roundly heart-shaped, on long stalks, the upper ones oval, heart-shaped and stem-clasping.

The white flowers appear in terminal racemes from May to July.

Culture &c. as for *A. albida*.

A. petræa.—A British plant 3-4 in. high, with smooth ciliated or rough leaves, the lower ones simple or bifid on long stalks entire toothed, the upper ones oblong linear. Flowers white or purplish with spreading broadly-clawed petals, appearing from June to August.

Culture &c. as for *A. albida*.

A. præcox.—A Hungarian plant 6-9 in. high, with smooth, entire, oblong acute and stalkless leaves. The white flowers with obovate wedge-shaped petals appear from April to June.

Culture &c. as for *A. albida*.

A. procurrens.—A native of Servia, about 9 in. high, with creeping stems. Leaves ovate, entire, smooth, with hairy edges, the lower ones narrowed into a stalk, the upper ones stalkless and pointed. In May and June the white flowers with obovate petals appear. The variegated form of this species is a very pretty rock-plant or for edgings.

Culture &c. as for *A. albida*.

A. rosea.—A native of Calabria, 12 in. high. The upper leaves are oblong, somewhat heart-shaped, more or less stem-clasping, scabrous with branched hairs. The rosy-purple flowers with oblong wedge-shaped petals are produced from May to July.

Culture &c. as for *A. albida*.

A. verna.—A pretty annual 3-6 in. high, from S. Europe. The upper leaves are heart-shaped, stem-clasping, toothed and roughish with 3-parted hairs. Flowers in May and June, small, purple, with clawed petals.

Culture &c. as above for *A. arenosa*.

STREPTANTHUS.—A little known genus containing about 20 species of smooth annual or perennial herbs, having entire leaves, or the lower ones lyrate pinnatifid, the upper ones stalkless or stem-clasping. Flowers purple, rarely white or yellow, rarely with bracts, sometimes drooping. Of the 4 sepals, 2 or all are saccate at the base, often coloured, sometimes very broad. Petals having a straight or twisted claw.

Culture and Propagation.—The two species described below are annuals, and may be raised from seeds sown about March or April out of doors, or earlier on

a hotbed like other annuals (see p. 78). They may also be sown in autumn as soon as ripe, and in cold parts of the kingdom protected in a cold frame during the winter months.

S. hyacinthoides.—A simple stemmed or branching plant 2-3 ft. high, from N.W. America, having unstalked clasping, oblong-linear pointed leaves. The deep bluish-purple flowers appear in autumn, having lance-shaped pointed sepals, and spoon-shaped linear petals, with a reflexed limb.

Culture &c. as above.

S. maculatus.—A native of the same region as the preceding, and 18 in. or more high. Leaves oval oblong, 3-6 in. long, glaucous, somewhat acute, the upper ones having long and blunt lobes clasping the stem. The showy deep velvety purple flowers, with purplish sepals, appear late in summer, the stalklets of each flower being 3-4 in. long.

Culture &c. as above.

CARDAMINE (LADY'S SMOCK ; CUCKOO-FLOWER).—A genus of some 60 species of smooth herbs varying a good deal in habit, and not much cultivated. The leaves are stalked, entire, lobed or pinnately cut, differing greatly on the same plant.

Culture and Propagation.—These plants thrive in damp shady situations in any soil, and are easily increased by dividing the roots after flowering, and also by sowing the seeds in the open border as soon as ripe. They may be used in borders, rockeries, banks &c. The following are a few of the best kinds:—

C. asarifolia.—A native of S. France and N. Italy, 12-18 in. high, with smooth, stalked, roundish heart-shaped leaves, somewhat sinuately toothed. Flowers in early summer, in close racemes, white.

Culture &c. as above.

C. pratensis (Cuckoo Flower).—This is perhaps one of the most common wild flowers of our damp meadows, its pale purple or white flowers appearing early in spring. It is too common to need cultivation in the flower garden proper, but its double-flowered variety (*flore pleno*) is worth growing in the border.

Culture &c. as above. As the double variety does not usually produce any seeds it must of necessity be increased by division in spring. Cuttings of the shoots

may also be rooted in light rich soil in a shaded part of the border during the summer months.

C. rhomboidea.—A tuberous species from the United States; the lowest leaves are round, and rather heart-shaped, passing upwards into ovate or rhomboid-oblong, and almost lance-shaped, all somewhat angled and sparingly toothed. Flowers large, white, appearing in spring. The variety *purpurea* has rosy-purple flowers appearing earlier than those of the type.

Culture &c. as above.

C. rotundifolia.—A plant found wild on the mountains of Pennsylvania, about 6 in. high, with procumbent stems. Leaves smooth, roundish, slightly toothed, stalked. Flowers in early summer, white small, in a terminal raceme.

Culture &c. as above.

C. trifolia.—A dwarf plant 3-6 in. high, with creeping runners, native of the mountains of Central Europe. Leaves smooth, ternate, with rhomboid-roundish toothed leaflets. Flowers in spring, white, in a terminal cluster.

Culture &c. as above.

LEAVENWORTHIA.—A small genus of dwarf and pretty annuals with lyrate-pinnatifid leaves, and flowers either solitary on scapes or in loose racemes.

L. Michauxii.—A native of the United States, 3 in. high, with leaves in tufts, and rosy-lilac flowers with a yellow eye, produced in June. *L. aurea* is a yellow-flowered variety worth growing.

Culture and Propagation.—This species may be treated as a half-hardy annual, being raised from seeds in the usual way in gentle heat in spring, afterwards transferring the young plants to the open ground at the end of May or beginning of June.

LUNARIA (HONESTY ; PETER'S PENCE).—A genus containing 2 species of annual, biennial or perennial herbs, with stalked, entire, heart-shaped leaves and rather large flowers in erect terminal racemes.

L. annua (L. biennis).—This charming plant is well known in gardens. It is a native of N. Europe, and about 2-3 ft. high, with deep green heart-shaped and irregularly toothed leaves, and racemes of beautiful scentless violet-lilac

flowers produced from May to July. There are several varieties, chiefly differing in the colour of the flowers—white, and various shades of purple. The great charm of the plant, however, lies in its large flat elliptic silvery seed pods, like opaque spectacles, which are borne in such profusion, and so much used for room decoration during the autumn and winter months.

There is a variegated form in which the leaves are broadly edged with whitish or creamy yellow.

Culture and Propagation.—Honesty should be raised from seeds sown in the open border every spring, and the seedlings may be either thinned out or transplanted early in autumn or preferably in spring to their flowering quarters for the following season. A good sandy loam suits them best, but any rich garden soil will produce fine specimens. The plants should not be nearer than about 18 in. to each other, and if the leading shoot is pinched out, fine bushy plants and plenty of blossom will be obtained by the development of the side shoots. As the young and tender shoots are greedily devoured by slugs, a watch must be kept on these marauders. A dusting of lime and soot early in the morning while the dew is still on the ground will keep them at bay.

L. rediviva is a vigorous, hairy, branching perennial species 2-3 ft. high, with large, heart-shaped, deeply toothed leaves on long stalks, and racemes of purplish fragrant flowers produced in early summer. The fruits or seed pods are smaller than those of the Common Honesty and also less rounded, but they may be similarly used.

Culture &c. as above. Although not so well-known as its biennial relative, this perennial species, which is a native of the Alps, is ornamental in the rockery or flower border if grown in masses for effect. It prefers a good sandy soil and a somewhat shaded position facing north or north-west. Seeds may be sown as recommended above for *L. annua*, but the established plants may also be divided at the root either about September or in spring when growth is about to commence. Cuttings of the non-flowering side and basal shoots may also be rooted during the summer months in a shady border or in a cold frame.

SELENIA.—A genus of 2 species of small and not well-known annual herbs, with pinnatisect leaves, and terminal leafy racemes of yellowish flowers. Sepals spreading, coloured, sub-equal. Petals erect. Glands 10, hypogynous.

S. aurea.—A native of the United States, with linear oblong pinnatifid leaves 1-2 in. long, having 5-7 pairs of segments. The golden-yellow scented flowers, with greenish yellow sepals, appear about June, and last a long time.

Culture and Propagation.—This pretty annual grows about 9 in. high and may be raised from seeds sown in early spring in gentle heat, or out of doors in April and May. The seedlings may be either pricked out in mild weather or thinned out 6-9 in. apart in ordinary good garden soil.

FARSETIA.—A genus of about 20 species of hardy or half-hardy branched erect herbs or undershrubs, more or less hoary or downy, with entire alternate leaves, and racemose or spiked flowers, sometimes minute, white, yellow or purple. Sepals often erect, the lateral ones saccate at the base. Petals clawed.

Culture and Propagation.—Most of the Farsetias are pretty, and will grow in ordinary garden soil. They are good plants for rockeries, borders &c., and are easily increased by seeds sown in spring in gentle heat, or as soon as ripe in cold frames. The seedlings may be pricked out as soon as large enough to handle easily, and afterwards transferred to the open border about the end of May or beginning of June.

F. ægyptiaca.—A somewhat tender much-branched shrub 1 ft. high, from N. Africa, with linear hoary leaves, and white flowers in July.

Culture &c. as above. Grows best in sandy loam and peat in sheltered spots.

F. clypeata.—A native of S. Europe, 1-2 ft. high, with oblong spreading leaves, and yellow flowers in June.

Culture &c. as above.

F. lunarioides.—A sub-shrubby species about 1 ft. high, from the Greek Archipelago. Leaves oblong-obovate, stalked, hoary. Flowers in June, yellow, with whitish sepals.

Culture &c. as above.

AUBRIETIA (PURPLE ROCK CRESS).
A small genus of evergreen, more or

less tufted, downy or hoary perennials, with entire or angularly toothed leaves, and few flowered racemes.

Aubrietias are charming plants for the rockery, where they make dense carpets of sage-green leaves and purple flowers. They may also be used for edgings to borders, shrubberies &c.

Culture and Propagation.—Aubrietias thrive in a deep rich loam, and are easily propagated by seeds sown in spring either in gentle heat about March or in the open border about April and May. The seedlings are pricked out into light soil, and about the end of September may be transferred to their permanent positions.

Cuttings may also be rooted during the summer months in light sandy soil in partially shaded borders, and the plants thus obtained may be transplanted as in the case of seedlings. Aubrietias may also be increased by layering the long slender branches after flowering, covering them with sandy leaf soil; and dividing the plants in autumn is likewise an easy and certain method of increasing the stock.

A. deltoidea.—A native of the mountains of S. Europe, 2-4 in. high, having roughish rhomboidal leaves covered with very short stellate hairs. The lilac-purple flowers are produced in great profusion in early spring, and almost hide the foliage. The petals are twice as long as the sepals, and have long claws. There is a charming variegated form in which the leaves are conspicuously edged with yellowish-white. It is elegant for rockeries and border edgings, and as it does not seed freely, is best increased by means of cuttings, layers or division as stated above.

The following are really only botanical varieties of *A. deltoidea*, but they are more or less distinct, and considered as species by some authorities; and to them may be added the forms known as *Columna*, *Leichtlini*, and *Mooreana*, all with deep shades of purple.

A. Bougainvillei is very dwarf and compact in habit, having light violet-purple flowers with very even imbricating petals.

Culture &c. as above.

A. Campbellei (*A. Hendersoni*).—This is a vigorous-growing form with larger deep violet-blue flowers than *A. deltoidea*. The variety *grandiflora* with a loose

habit is very near this, and looks very pretty in masses.

Culture &c. as above.

A. Eyrei.—A very fine variety with large rich deep violet-purple flowers, and a free branching habit. *A. olympica* is closely related, if not actually the same as this.

Culture &c. as above.

A. græca.—A strong-growing variety from Greece, about 4 in. high, and with a neat compact habit. The flowers, which are probably larger than those of any other variety, are a beautiful shade of pale purple. *Superba* is a form with rather deeper coloured flowers.

Culture &c. as above.

A. purpurea.—This has broader leaves, larger purple flowers—which also appear later—a more erect habit and more leafy stems than *A. deltoidea*. The variegated form is useful for carpet-bedding and as an edging to small beds &c. *Dr. Murie* is a beautiful garden form of *A. purpurea*.

Culture &c. as above.

A. violacea.—This is a very fine variety with large deep violet-purple flowers fading to reddish-violet, and has a very effective appearance.

Culture &c. as above.

VESICARIA (BLADDER POD).—This genus contains about 20 species of branched annual or perennial herbs, with entire, sinuate or pinnatifid leaves, and large, rarely small, yellow or purple flowers, varying in form. Fruit pods globose or inflated.

Culture and Propagation.—Vesicarias grow readily in ordinary soil, and are suitable for sunny parts of rock-work. The annual and perennial species are reproduced from seed which is produced freely in favourable seasons, and may be sown in cold frames either as soon as ripe, or in gentle heat in spring. The seedlings are pricked out into light rich soil when large enough, and by the end of May or beginning of June will be ready for transplanting to the border or rockery as required. To secure good effects, several plants should be grouped together about 9-12 in. apart. The perennial kinds may also be increased from cuttings put under a hand-glass or in a cold frame during the summer or autumn months.

V. arctica.—A perennial about 1 ft. high, from N. America. Leaves in clusters,

oblanceolate and linear spoon-shaped, of a beautiful silvery colour. Flowers in August, yellow, in dense racemes.

Culture &c. as above. Increased by seeds or cuttings.

V. gracilis.—An annual species, 6 in. high, native of Texas. The thread-like rigid and slightly rough stems have lance-shaped entire or slightly angled leaves, the lower ones stalked, more or less spoon-shaped. Flowers in June, yellow, with spreading obovate and nearly sessile petals.

Culture &c. as above. Increased by seeds.

V. græca (*Alyssum utriculatum*).—A perennial plant from Greece. Leaves of the sterile branches thick, oblong, spoon-shaped, slightly acute; those of the fertile stems stalkless, erect, acute, with hairy and often slightly toothed margins. Flowers in summer, yellow.

Culture &c. as above. Increased by seeds and cuttings.

V. grandiflora.—A downy annual from Texas, 1 ft. high, with erect flexuose stems. Lower leaves stalked, more or less lyrate pinnatifid, the upper ones stalkless, sinuate-toothed. Flowers in July, large, yellow, with rounded spreading shortly clawed petals.

Culture &c. as above. Increased by seeds.

V. utriculata.—A perennial from S. Europe, 1 ft. high, having oblong, entire, smooth leaves, the lower ones with hairy edges and somewhat spoon-shaped. Flowers from April to June, yellow, closely resembling those of the Wall-flower; calyx bisaccate at the base.

Culture &c. as above. Increased by seeds and cuttings.

ALYSSUM (MADWORT).—A genus containing about 80 or 90 species of annuals or dwarf branching shrubby perennials often covered with hoary stellate hairs. Leaves sparse, or tufted at the base, entire, often linear. Racemes without bracts. Flowers white or yellow, often inconspicuous.

Culture and Propagation.—The Madworts are most effective as rock plants or in front of other plants in the mixed border. They grow freely in ordinary well-drained soil, and are increased by cuttings during the summer months in a shaded border; division of the roots in

autumn or spring; or by seed sown out of doors in April and May, or indoors in gentle heat earlier in spring. The seedlings are pricked off and are usually ready for transplanting to their permanent positions about September or spring.

The following are some of the kinds most frequently met with:—

A. alpestre.—A pretty greyish-looking perennial 3 in. or more high, from South Europe, with ovate hoary leaves, and simple racemes of yellow flowers in June. A good plant for chinks of old walls. The variety *obtusifolium* is somewhat rare, with bluntly obovate spoon-shaped leaves, silvery beneath.

Culture &c. as above.

A. atlanticum.—A native of S. Europe 6–12 in. high, with lance-shaped, hoary and hairy leaves, and yellow flowers in June.

Culture &c. as above.

A. gemonense.—A desirable Italian species about 1 ft. high, with lanceolate, entire, greyish velvety leaves, and yellow flowers produced in close corymbs from April to June.

Culture &c. as above.

A. macrocarpum.—A native of S. France, less than 1 ft. high, with oblong, blunt silvery leaves, and racemes of white flowers in June.

Culture &c. as above.

A. maritimum (*Sweet Alyssum*).—A pretty British and European species 4–10 in. high with linear lance-shaped downy leaves 1–1½ in. long and racemes of small white sweet-scented flowers produced from June to September. The variety *compactum* is a closer growing plant forming rounded tufts, and continues to flower during the summer and autumn months. There is also a variegated variety with yellowish-white bordered leaves. This rarely seeds, and in any case is best increased by cuttings or division.

Culture &c. as above. Although in reality a perennial, the Sweet Alyssum is frequently treated as an annual. Seeds may be sown in either autumn or spring, and the seedlings are transplanted about the end of May, or in autumn, according to the season at which the seeds were sown.

A. montanum.—A spreading tufted perennial 2–4 in. high, native of the Alps and Pyrenees. Leaves somewhat hoary,

rough with stellate hairs, lower ones obovate, upper ones oblong. Flowers from May to July, yellow, sweet-scented.

Culture &c. as above.

A. olympicum.—A native of N. Greece 2-3 in. high, with small, greyish, spoon-shaped leaves without stalks. Flowers in summer, small, deep yellow, in roundish corymbose heads.

Culture &c. as above.

A. orientale.—A native of Crete, 1 ft. high, with lance-shaped, repandly-toothed wavy and downy leaves. Flowers in May, in corymbose clusters.

Culture &c. as above.

A. podolicum.—A small alpine from South Russia, with a profusion of small white flowers in early summer.

Culture &c. as above.

A. pyrenaicum.—A tufted Pyrenean species 8-10 in. high, with roundish leaves woolly on the under surface. The white flowers appear from June to August, and are noticeable for the brownish anthers in the centre.

Culture &c. as above.

A. saxatile.—A well-known and beautiful species about 1 ft. high, from E. Europe, somewhat shrubby at the base. Leaves lance-shaped, entire, hoary. Flowers in April and May, bright yellow, freely produced, in loose panicles. The variety called *compactum*, which comes true from seeds, is particularly useful for rockeries and edgings on account of its dwarf bushy character. The variety *variegatum*, with yellowish-white leaves, is a pretty form, and does well in a sunny place in the rockery.

Culture &c. as above. The variegated form is best increased by means of cuttings.

A. serpyllifolium.—Also from South Europe, 3-4 in. high, somewhat woody at the base. Leaves $\frac{1}{4}$ - $\frac{1}{2}$ in. long, ovate, rough and hoary. Flowers from April to June, pale yellow, in simple racemes.

Culture &c. as above.

A. spinosum.—A native of S. Europe 4-8 in. high, resembling *A. macrocarpum*. Leaves lance-shaped, small and hoary, the branches being spiny when old. Flowers in early summer, small, white, in clusters at the ends of the branches.

Culture &c. as above.

A. tortuosum.—A Hungarian species, 6 in. high, shrubby at the base, twisted,

with rather lance-shaped, hoary leaves, and corymbose racemes of yellow flowers in June.

Culture &c. as above.

A. Wiersbeckii.—A native of Asia Minor, about 18 in. high, with roughish erect stems. Leaves 2 in. long, oval, oblong, acute, without stalks, narrowed at the base, and covered with rough prominences and fine hairs. Flowers in summer, deep yellow, about $1\frac{1}{2}$ in. across, in large corymbose heads.

Culture &c. as above.

A. wulfenianum.—A dwarf alpine Crucifer, native of Eastern Europe. The decumbent or trailing stems are 1-3 in. long, and the small oblanceolate leaves are covered with down. The golden-yellow flowers appear in summer in small compact corymbs.

Culture &c. as above.

DRABA (WHITLOW GRASS).—A genus containing, according to various authors, from 80 to 150 species consisting chiefly of very small, tufted, and hoary alpine plants, with entire leaves, the lower ones in rosettes. Racemes short or elongated. Flowers without bracts, often small, white or yellow, rarely purple or rose.

The Drabas are essentially rock plants, owing to their compact habit and to their love for sunny spots. For filling up nooks and crevices, on the top of old walls, ledges, copings &c., they are very useful, their cushions of leaves, thickly studded with white or yellow flowers, being at once effective and beautiful.

Culture and Propagation.—They grow easily in ordinary soil, and the perennial sorts may be increased by dividing the roots in early autumn. The annual and biennial species and also the perennials may be raised from seed sown in spring in the open border. If sown late in summer, annual kinds will flower the following year.

D. aizoides.—A brilliant species 2-3 in. high, native of S. Wales and Central Europe. Leaves narrow, lance-shaped, keeled, hairy at the edges, and arranged in neat rosettes. Flowers in March, bright yellow, in terminal racemes. The variety *dedeana* from Spain is a pretty plant with white flowers. It is sometimes regarded as a distinct species.

Culture &c. as above. Increased by seeds and division. This makes fine

cushions for the rock garden, and is a valuable early-flowering alpine plant.

D. Aizoon (*D. ciliaris*).—A somewhat vigorous species, 3 in. high, from the mountains of W. Europe. Leaves linear, acute, keeled, hairy-edged. Flowers in April, bright yellow, on naked hairy scapes. It ripens seed freely.

Culture &c. as above. Increased by seeds and division.

D. alpina.—A native of N. Europe, 3 inches high, with flat lance-shaped hairy leaves, and naked downy scapes of golden-yellow flowers produced in April.

Culture &c. as above. Increased by seeds and division.

D. aurea.—A biennial species from Greenland, about 6 in. high, with somewhat branched velvety stems, and oblong-linear, acute, entire, downy leaves. Flowers in May, with obovate, blunt, clawed petals.

Culture &c. as above. Increased by seeds.

D. bruniaefolia.—A loosely tufted plant, about 4 in. high, from the Caucasus. Leaves linear, somewhat keeled, acute, in loose rosettes. Flowers in June, yellow, on naked downy scapes.

Culture &c. as above. Increased by seeds and division.

D. ciliata.—A fine white-flowered species 2 in. high, from Croatia and Carniola, and very much like a miniature plant of *Arabis albidia*. Leaves rather leathery, smooth, with a cartilaginous margin slightly toothed and fringed with stiff hairs. Flowers in early summer, white, few, closely set.

Culture &c. as above. Increased by seed and division.

D. cinerea.—A Siberian biennial 3-6 in. high, with somewhat downy stems, Leaves oblong-linear, entire, scattered. Flowers in early spring, white.

Culture &c. as above. Increased by seeds.

D. cuspidata.—A native of Tauria, 3 in. high, nearly related to *D. Aizoon*, and probably only a form of it. Leaves in dense rosettes, linear, acute, keeled, hairy-edged. Flowers in spring, yellow, in terminal racemes; scapes naked, hairy.

Culture &c. as above. Increased by seed and division.

D. glacialis.—This is a native of Siberia and the granitic Alps of Switzerland, about 2 in. high and like a small form of *D. aizoides*. Leaves linear and lance-shaped, entire, with stellate hairs. Flowers in May, bright golden-yellow; scapes naked, with a starry down.

Culture &c. as above. Increased by seeds and division.

D. lapponica.—A native of the Lapland Alps, 2-3 in. high, with lance-shaped, entire, rather hairy leaves. Flowers in May, white; scapes naked, very smooth.

Culture &c. as above. Increased by seeds and division.

D. Mawi.—A lovely rock plant with masses of bright green densely tufted foliage. It is a native of Spain. Leaves linear-oblong, blunt, shiny, margin pectinate, with stiffish incurved or spreading bristles. Flowers in spring, white, $\frac{3}{4}$ in. across; sepals deeply concave, bristled behind, green tipped with red-brown.

Culture &c. as above. Increased by seeds and division.

D. nivalis.—A native of Arctic Europe 1-2 in. high, more compact in habit than *D. lapponica*. Leaves linear-oblong, rather hairy, with fringed edges. Flowers in April, white; scape naked or one-leaved, smooth.

Culture &c. as above. Increased by seeds and division.

D. pyrenaica (*Petrocallis pyrenaica*). A beautiful Alpine 2-3 in. high, native of the mountains of S. Europe. Leaves wedge-shaped, palmately 3-lobed; stems shrubby at the base dividing into many small branches. Flowers in April and May, at first white, pale lilac-purple, then faintly veined, sweet-scented, borne in short few-flowered racemes.

Culture &c. as above. Increased by seeds and division.

D. rupestris.—A compact-growing species 2-3 in. high, native of Norway, Scotland, and North America. Leaves crowded, lance-shaped, almost entire, hairy. Flowers in summer, white, few, small, on almost leafless stems.

Culture &c. as above. Increased by seeds and division.

D. Sauteri.—A Swiss plant 4 in. high, with stiff spoon-shaped leaves, fringed

with hairs. Flowers in spring, yellow; scapes smooth.

Culture &c. as above. Increased by seeds and division.

D. tridentata.—A native of the Caucasus readily recognised by its 3-toothed hairy obovate leaves, narrowed at the base into a stalk. Flowers in spring, golden-yellow, in terminal racemes; scapes naked, smooth. This species is also known as *D. hispida*, on account of its hairy leaves.

Culture &c. as above. Increased by seeds and division.

D. violacea.—A native of the Andes of Quito, 6-12 in. high, with branching subshrubby stems, and opposite ovate downy leaves. Flowers deep violet-purple.

Culture &c. as above. Increased by seeds and division.

SCHIZOPETALON.—A genus consisting of 5 species of pretty-looking erect slightly branched annual hoary herbs with alternate, sinuate-toothed or pinnatifid leaves. Racemes terminal, with leafy bracts. Flowers purple or white. Sepals erect, nearly equal at the base. Petals clawed, pinnately lobed.

S. Walkeri.—A curious half-hardy annual, 1-2 ft. high, native of Chili. The whole plant is covered with a branched down, and has alternate, sinuately pinnatifid leaves, the upper ones near the flowers being more or less linear and entire. Flowers from May to August, white, almond-scented, fringed, and borne in long racemes, each pedicel having a linear bract. The prettily cut petals are often suffused with violet or purple beneath.

Culture and Propagation.—The seeds of this plant should be sown in the open in April or May in light, warm rich soil, and the seedlings should be left to flower during the summer and autumn where sown, as they do not transplant well. Cold damp shady spots should be avoided for growing this interesting plant; and to obtain a good effect, the seeds should be sown in fairly large patches, as thinly as possible. If the plants are too thick they must be thinned out.

HESPERIS (DAME'S VIOLET; ROCKET).—This genus contains about 20 species of ornamental biennial or perennial erect hairy herbs with ovate or oblong, entire, toothed or lyrate leaves.

Flowers rather large, in loose bractless racemes, often variously coloured, sometimes fragrant. Sepals erect, lateral ones gibbous at the base. Petals clawed.

Culture and Propagation.—The Rockets thrive in a somewhat damp sandy loam, and are easily reproduced from seeds. These are sown in April and May out of doors in light sandy soil, or earlier in the year under glass in gentle heat. The seedlings are pricked out when large enough to handle easily, and may be moved later on in autumn to their flowering positions. The seeds may also be sown as soon as ripe in cold frames, and kept protected during the winter months, and the seedlings may be placed out of doors at the end of May.

The plants may also be divided in spring, but as this would to a certain extent interfere with early flowering, the plants are on the whole better divided any time during August and September. They should afterwards receive a good soaking with water to settle the soil and prevent the plants 'flagging' or wilting too much.

H. grandiflora.—The origin of this plant is unknown. The lower leaves are oblong-ovate, blunt, the upper ones lance-shaped. The purplish flowers appear in summer in many-flowered crowded racemes.

H. matronalis (Dame's Violet or Rocket; Damask Violet; Common Rocket).—This pretty old garden plant grows wild from S. Europe to Russian Asia, and is 2-3 ft. high. Leaves 2-5 in. long, shortly stalked or tapering at the base, more or less ovate-lance-shaped, finely and irregularly toothed or serrate. Flowers from May to July, $\frac{3}{4}$ in. across, white or lilac, scented in the evening.

The double white and purple-flowered kinds (*flore pleno*) are much more highly valued as garden plants, not only for their pretty flowers, but also for their delicious fragrance.

Culture &c. as above. The seeds of this plant may be sown in the chinks or crevices of old walls, ruins &c., where it seems to be more at home than anywhere else. The double forms of the Dame's Violet (*H. matronalis*), however, are more easily increased by carefully dividing the roots, at least every alternate year, or from cuttings of the young shoots inserted in the open ground in a shady place.

At one time the double varieties were more extensively grown than they are at the present day.

H. violacea. — A pretty biennial or perennial species 1-2 ft. high, native of Asia Minor, with tufts of oblong downy or hairy leaves irregularly toothed on the margins. The bright purple or violet flowers, with deeper coloured veins, are produced from April to June in large trusses well above the foliage, and are highly effective and ornamental in the border or rockery.

Culture &c. as above. This species, although really a perennial, is usually raised from seeds sown in autumn or spring.

MALCOLMIA.—A genus of about 20 species of beautiful branching and often prostrate hairy herbs, having alternate, entire, or pinnatifid leaves. Flowers in loose racemes, bractless, white or purple.

Culture and Propagation.—The Malcolms grow easily in ordinary good garden soil, and may be raised from seeds sown thinly from spring till autumn, to obtain a succession of bloom. The general treatment is the same as recommended above for the Dame's Violet (*Hesperis*).

M. chia.—A branching plant 6-12 in. high, native of Chio. Leaves downy beneath, entire or rarely toothed, lower ones obovate or spoon-shaped, upper ones narrower and more acute. Flowers in June, purplish-lilac.

Culture &c. as above.

M. littorea. — A native of the Mediterranean region 6-12 in. high, with lance-shaped linear, nearly entire, hoary leaves. Flowers from June to November, bright pink-purple, the large delicate petals not being veined. Seed pods hoary.

Culture &c. as above.

M. maritima. — This pretty annual is commonly known as the 'Virginian Stock.' It is 6-12 in. high, native of Europe, having erect branching stems, and elliptic, blunt, entire leaves, narrowed at the base. Flowers from spring to autumn, lilac, rose, red or white, fragrant.

Among the many varieties may be mentioned *alba*, white; *alba nana*, also white but dwarfer; and *Crimson King* or *Kermesina*, dwarf, deep red.

The Virginian Stock is very effective in masses in borders, beds &c. It grows

readily in almost any part of the garden and bears in great abundance its masses of sweet-scented blossoms. It is excellent for bordering beds of taller plants, and masses here and there in the rockery produce a charming picture.

Culture &c. as above.

ERYSIMUM (HEDGE MUSTARD).—A genus containing, according to various authors, from 70 to nearly 120 species of biennial or perennial, hairy or sometimes hoary-looking herbs. Leaves variable, narrow, heart-shaped, stem-clasping, or pinnately cut, linear or oblong, entire, sinuate toothed, or rarely pinnatifid. Racemes bractless. Flowers mostly yellow, sometimes purple, and scented.

Culture and Propagation.—Very few species are worthy of cultivation, those described below being among the best and most showy border plants. They are easily raised from seeds sown in spring or autumn in the open border. From the end of March to the end of June sowings of the annual species may be made at intervals of 2 or 3 weeks, so that a long succession of blossom is maintained. The perennial species may not only be raised from seeds in the same way as the annuals but also increased by dividing the roots in autumn. They all grow freely in ordinary good garden soil in open sunny situations. Grown in large masses they are very effective and telling on the landscape owing to the warmth and brilliancy of colour of their flowers.

E. alpinum (*Cheiranthus alpinus*).—A Norwegian perennial 6 in. high, having straight simple stems, and lance-shaped distantly toothed leaves, covered with a starry down. Flowers in May, sulphur-yellow, sweet-scented, borne in loose racemes, and reminding one at a distance of some of the yellow Primulas, although the flowers, of course, have only 4 petals instead of 5.

Culture &c. as above. This pretty plant is best known as a *Cheiranthus*.

E. asperum.—A N. American biennial, about 8 in. high, with greyish hairy stems. Leaves linear oblong, lower ones toothed, runcinate, rough, downy. Flowers in July, yellow, the petals having white claws.

Culture &c. as above.

E. marschallianum. — A biennial, native of the Caucasus, about 1 ft. high, with lance-shaped toothed leaves narrowed

at the base, and bright yellow flowers appearing in summer.

Culture &c. as above. This species may also be increased by placing cuttings of the flowerless shoots in light sandy soil under handlights in August and September, and protecting them until the following spring in case of severe frosts in winter.

E. ochroleucum (*Cheiranthus ochroleucus*).—A procumbent perennial, with branching stems, 6–12 in. high, native of the Alps of Java. Leaves oblong lance-shaped, somewhat toothed, hairy or smooth. Flowers from April to July, beautiful sulphur-yellow, faintly scented, petals obovate. The variety *helveticum* has narrower entire or toothed leaves, with somewhat ascending hairy stems.

Culture &c. as above. *E. ochroleucum* is a good rock plant, and if divided every year seems to do better than by other methods of increase. It may, however, also be increased by cuttings in the same way as *E. marschallianum* and by seeds. It is excellent for carpeting the soil and trailing over stones in the rock garden.

E. perofskianum.—This is a most showy species from the Caucasus, about 1 ft. high, with oblong lance-shaped leaves, and brilliant reddish-orange flowers in great masses during the spring, if the seeds are sown in autumn. By sowing in spring, flowers will appear in summer and autumn. It will grow anywhere.

Culture &c. as above.

E. pulchellum.—A very compact-growing perennial species attaining a height of about 1 ft. with dense tufts of oblong-elliptic toothed leaves. The sulphur-yellow flowers are freely produced in spring and summer and emit a faint odour. It is a native of the East, and is an excellent plant for dry borders. Owing to its tufted masses of foliage it makes a good carpet plant, and rivals the Aubrietias in this respect.

Culture &c. as above.

E. pumilum.—A charming perennial rock plant only 1–3 in. high, native of the Eastern Pyrenees. Leaves linear, lance-shaped, slightly toothed, greyish-green. Flowers in summer, pale sulphur-yellow, fragrant.

Culture &c. as above.

E. rheticum.—A somewhat rare plant in cultivation. In summer its clear

yellow blossoms are produced in great profusion above the dense masses of foliage.

Culture &c. as above.

E. Wahlenbergi.—A branching and showy perennial species about 2 ft. high, native of Transylvania. Its stems are clothed with lance-shaped toothed leaves and the bright yellow flowers are freely produced during the summer months.

Culture &c. as above.

STANLEYA.—A genus containing about 6 species of smooth perennial glaucous herbs resembling the *Arabis* in habit. Leaves undivided or pinnatifid. Racemes elongate, straight, many-flowered, bractless. Sepals short, spreading, equal at the base. Petals narrow, elongated, with long claws. Anthers twisted.

S. pinnatifida.—This pretty species from California is the only one at present grown. The thickish leaves are interruptedly pinnatifid, and the yellow flowers appear in May in great abundance on tall racemes.

Culture and Propagation.—It grows freely in soil with plenty of humus, and may be increased by seeds sown under glass in February or March or out of doors in April and May. Seeds may also be sown as soon as ripe in cold frames, and the seedlings may be pricked off in light soil and kept under protection during the winter months until favourable weather occurs for planting out in May. The plants may also be increased by division of the roots in early autumn or spring.

HELIOPHILA.—A South African genus of little-known annual or perennial herbs, or branching smooth or downy undershrubs, with entire, toothed, sinuate, or pinnatisect leaves. Racemes bractless. Flowers white, yellow, rose, or blue. Pedicels often slender. Pods often pendulous or deflexed.

Culture and Propagation.—The following species—all annual—are easily grown in ordinary good garden soil, and may be raised from seed sown out of doors in April and May, or sown in spring under glass or on a gentle hotbed. The seedlings, if raised by the latter method, should be pricked off into light sandy soil and gradually hardened off so as to be ready for transferring to the open border about the end of May or beginning of June. A warm sunny position suits them best.

H. amplexicaulis.—A plant about 9 in. high, with oblong, heart-shaped stem-clasping entire leaves, the lower ones opposite, the upper alternate. Flowers from June to September, small, varying from white to purple.

Culture &c. as above.

H. coronopifolia.—This grows 1-2 ft. high, having pinnately parted leaves with entire linear lobes, and bluish-violet flowers from June to September.

Culture &c. as above.

H. pilosa.—Grows 6-12 in. high. Leaves hairy, lower ones lance-shaped, pinnatifid, upper ones linear, entire. Flowers in summer, blue. The variety *incisa* has linear, wedge-shaped leaves, trifid, rarely 5-fid at the apex, with linear or pointed lobes.

Culture &c. as above.

VELLA (FALSE CYTISUS; CRESS ROCKET).—A small genus of much-branched, rigid, woody, erect, sometimes spiny undershrubs, natives of Spain.

V. Pseudo-cytisus grows 2-3 ft. high, and has alternate, obovate, entire leaves, and yellow flowers in early spring, the long petals having dark purple claws.

Culture and Propagation.—This species, if grown in a dry, warm, sunny border, is hardy enough to stand the winter in most parts. It is increased by cuttings of the young shoots placed under a hand-glass during the summer months. Seeds may also be sown as soon as ripe in cold frames or in spring in gentle heat, and the young plants may be placed in the open ground about the end of May.

V. spinosa.—A much-branched spiny shrub 6-8 in. high, native of the Spanish mountains. The lower leaves are fleshy, and more or less lance-shaped, the upper ones linear with slender spines in the axils. The yellow flowers appear in early summer, and have long-clawed obovate spoon-shaped petals veined and netted with violet or purple.

Culture &c. as above. This species is very rarely seen, even in botanic gardens, but it makes a good rock plant in warm sheltered positions. Another species sometimes seen is *V. annua*—a mere annual weed not worth growing.

IONOPSIDIUM (VIOLET CRESS).—A genus of 2 species of small, smooth annual herbs, with stalked or unstalked,

spoon-shaped or rounded, entire or 3-lobed leaves. Flowers small, violet, white or flesh-coloured.

I. caule.—A charming little plant rarely exceeding 2 in. high, native of Portugal and North Africa, and covered all over during the summer and autumn with lilac, or white tinged with violet flowers. These emit a sweet honey-like fragrance and are borne on slender stalks which issue from the axils of the small roundish leaves. There is a variety with pure white flowers.

Culture and Propagation.—This little annual flourishes on rockeries or rough places in ordinary soil, and in somewhat shady positions, where it frequently reproduces itself annually from self-sown seeds. Grown in pots or small shallow pans it is also very effective as a window plant. Seeds may be sown at intervals of 2 to 3 weeks in the open border from the end of March to the end of September to secure a succession of flower. Under favourable circumstances this plant comes into blossom about 8 or 10 weeks, more or less, after the seeds have been sown.

BIVONÆA.—A genus with only one species here described.

B. lutea.—A pretty little annual, native of Sicily, 3-6 in. high, with thread-like, sparingly branched stems. Leaves alternate, lower ones stalked, the others without stalks, heart-shaped, stem-clasping at the base, ovate, toothed, rather blunt. The small yellow flowers appear in April on terminal racemes, elongating as they grow. Pedicels thread-like, bractless.

Culture and Propagation.—This species thrives in dry sandy soil, and may be raised in spring from seeds sown in the open border where the plants are to bloom. If too thick, the seedlings may be thinned out so that the remaining plants will have sufficient space to develop properly. It is suitable for rockeries, the edges of borders &c.

ÆTHIONEMA.—A genus of pretty annual or perennial smooth herbaceous plants or undershrubs, with round stems and slender branches. Leaves without stalks, glaucous, the lower ones sometimes opposite. Flowers small, racemose, clustered, fleshy or purple; pedicels slender, bractless. The 4 larger stamens are winged, or prolonged into a tooth.

Culture and Propagation.—These plants grow freely in well-drained sandy

loam in the flower border, and sunny situations, but dwarfier-growing species are more suitable for the rock garden. The annual and biennial kinds may be sown from April to June in the open border where they are to bloom. The perennials are also raised from seed, or from cuttings put in during the summer and shaded till rooted. In northern parts it is safer to protect the perennials raised from cuttings the first year in cold frames until favourable weather in spring when they may be planted out.

Æ. Buxbaumii (*Thlaspi arabicum*).—A pretty erect branching annual, 6 in. high, native of Thrace, with oblong spoon-shaped glaucous leaves, and crowded racemes of pale red flowers in June.

Culture &c. as above. Raised from seeds annually.

Æ. coridifolium (*Iberis jucunda*).—A pretty perennial, shrubby at the base, with erect stems 6-8 in. high. Leaves numerous, oblong, linear, glaucous, with a brownish point, and narrowed at the base. Flowers in June, rosy-lilac, prettily veined, and in dense terminal rounded racemes.

Culture &c. as above. This species, being a native of Asia Minor, is not altogether hardy in all parts of the United Kingdom. It is therefore better to grow it in rich light and well-drained soil in warm, sunny and sheltered parts of the rock garden where it will not be injured by the severe blasts from the north and east.

Æ. gracile.—A shrubby perennial, about 8 in. high, native of the sandy hills of Carniola, with lance-shaped pointed leaves and crowded terminal racemes of purplish flowers in June.

Culture &c. as above. Increased by seeds and cuttings.

Æ. grandiflorum.—A handsome bushy perennial about 1 ft. high, from Mount Lebanon, with ovate oblong, glaucous leaves. Flowers from May to August, of a warm shaded rose, in crowded terminal racemes. An effective rock plant.

Culture &c. as above. Increased by seeds and cuttings.

Æ. membranaceum.—A neat dwarf shrub 3-6 in. high, with thread-like branches, and native of Persia. Leaves oblong, linear, obtuse, various, somewhat fleshy, and clothing the stem rarely closely. Flowers in June, purple or rose, in small

dense terminal racemes. Pods overlapping each other, roundish, with a very broad membranous margin, notched at the top.

Culture &c. as above. Increased by seeds and cuttings.

Æ. monospermum.—A pretty Spanish biennial 3-6 in. high, with stiffish branches, and leathery, more or less ovate, blunt leaves. Flowers in June, large, purple. Pods one-celled and one-seeded.

Culture &c. as above. Increased by seeds.

Æ. pulchellum.—Perhaps the handsomest and hardiest species, resembling *Æ. coridifolium*, but not yet very well known.

Culture &c. as above.

Æ. saxatile.—A pretty Spanish annual about 8 in. high, with lance-shaped, acute leaves, and loose terminal racemes of lilac-rose or purplish flowers in May and June.

Culture &c. as above. Increased by seeds. It loves a rather dry and rich loamy soil.

EUNOMIA.—A genus of 2 species of pretty little half-hardy evergreen, branched or tufted undershrubs or herbaceous plants, native of Asia Minor. Leaves stalkless and stem-clasping, entire, thickish. Flowers in short racemes, white.

E. oppositifolia.—A plant with decumbent branched stems 6-12 in. high, with opposite, almost round, entire, smooth leaves, and terminal racemes of white flowers in June.

Culture and Propagation.—This species may be grown in sheltered parts of the rockery in ordinary soil, and can be increased by cuttings taken in summer and put under a glass. Or seeds may be sown in April or May in the open border where the plants are to bloom. The seedlings may be thinned out. If sown earlier in the year, a little bottom heat is required and the seedlings may be pricked out and grown on for planting out at the end of May.

SCHOUWIA.—A genus of 3 species of very smooth branching annuals, natives of Arabia, with entire leaves, the upper ones deeply auricled and stem-clasping. Flowers at first corymbose, afterwards racemose, purple; pedicels slender. Sepals nearly erect, the lateral ones broader. Stamens free, without teeth.

S. arabica is a pretty annual about 1 ft. high, with rosy-purplish flowers in

June. The other characters as described above.

Culture and Propagation.—It grows freely in light sandy soil, and seeds may be sown in the open border in spring from the beginning of April to the end of June if a succession of flowers is required.

IBERIS (CANDYTUFT).—A genus having about 20 species of annual or biennial smooth branched herbs or undershrubs, with entire or pinnatifid, often fleshy, leaves. Flowers racemose or corymbose, white or purple, the outer ones radiating. Sepals equal at the base. Petals 4, the 2 outer ones larger than the others.

Culture and Propagation.—All the Candytufts are easily grown in ordinary garden soil, in exposed sunny situations. The annuals and biennials are raised by seeds sown in the usual way, varying the date of sowing according to the period when it is required to have the plants in bloom. Thus, seeds may be sown as soon as ripe in cold frames so that a stock of strong sturdy plants will be ready for planting out in spring in mild weather. In February and March seeds may be sown in gentle heat, afterwards pricking the seedlings out, so as to enable them to develop previous to their being planted out about the end of May. In April and May seeds may also be sown in the open border where the plants are to bloom. When the seedlings are well above ground they must be thinned out, but not transplanted.

In this way a good succession of flowers may be obtained from early summer to the end of autumn.

The sub-shrubby perennial kinds are valuable plants for the border or rock garden, on account of their deep green masses of foliage, and clusters of flowers, which last a long time. The perennials may be raised from seeds, but it is generally more convenient to root cuttings during the summer months in a shaded border or under handlights; or to divide the plants after flowering. The stems may also be bent down and covered with light rich soil. In this way roots will develop as from layers, and the shoots may be detached in spring.

I. affinis.—A pretty annual or biennial species, native of France, rarely exceeding 8 or 9 in. high, with a much-branched tufted habit, and pinnately divided leaves. The flowers appear in

spring and summer, and are of a pure white, the sepals only being tinted with violet before the buds open. An excellent little plant for borders and edging.

Culture &c. as above. Increased by seed.

I. amara (Common Candytuft).—A British annual 6–9 in. high, with lance-shaped, acute, slightly toothed leaves, and racemes or corymbs of white flowers in summer. The variety *hesperidifolia* is larger and prettier than the type, and is also more vigorous in growth.

Culture &c. as above. Increased by seeds.

I. bernardiana (I. Bubani).—A Pyrenean annual, 6 in. high, with spoon-shaped, lobed, deep glossy green leaves in dense compact rosettes, and corymbs of pink flowers in summer.

Culture &c. as above. Increased by seeds.

I. ciliata.—A rather smooth herbaceous biennial about 9 in. high, native of S.W. Europe. Leaves linear, entire, edges hairy at the base. Flowers in June and July, white. The variety *taurica* may be treated as an annual or biennial. It has somewhat fleshy leaves fringed with hairs, the lower ones spoon-shaped, sometimes with 2 teeth at the apex; the upper ones linear. Flowers white, corymbose, a little earlier than *ciliata* proper.

Culture &c. as above. Increased by seeds.

I. corifolia.—A Sicilian alpine 3–4 in. high, probably a small variety of *I. sempervirens*. Leaves linear, entire, blunt, smooth, in dense tufts. It has masses of small white flowers early in May, and looks well in the rock garden near the edge.

Culture &c. as above.

I. coronaria (Rocket Candytuft).—A beautiful annual, the native country of which is unknown. It is about 1 ft. high, with lance-shaped, entire, leathery leaves, and numerous long dense heads or spikes of pure white flowers, borne well above the foliage in summer. The form known as 'Giant Snowflake' is very fine.

Culture &c. as above. Increased by seeds.

I. correaefolia.—A splendid evergreen garden hybrid (probably between *sempervirens* and *saxatilis*) about 1 ft. high,

with woody, slender, trailing branches. Leaves spoon-shaped, blunt, entire, smooth, about $1\frac{1}{2}$ in. long. Flowers in May and June, white, large, in dense flat heads, lengthening with age into spikes about 3 in. long, the lower flowers opening first.

Culture and Propagation.—This is an excellent plant for almost any part of the flower garden, but especially for rockeries, edges of borders, nooks &c. As it does not come true from seed, it is best increased by cuttings or layers. It grows well in dry soil and hot sunny places.

I. gibraltarica.—A handsome but somewhat straggling evergreen, 1-2 ft. high, native of Gibraltar. Leaves wedge-shaped, blunt, fleshy, distinctly toothed at the apex, slightly ciliated, about 2 in. long. Flowers from Easter to Whitsuntide, large, white, often tinged with pink or red, in corymbose heads.

Culture &c. This species requires a well-drained soil in somewhat sheltered spots, as it may not be quite hardy in all parts of the country. The variety *hybrida* is a denser growing plant than the type, and has masses of creamy white flowers gradually deepening to a pretty rose-purple. Both species and variety are excellent plants for the rockery or flower border, and may also be grown to advantage in pots for the decoration of green-houses and conservatories in the early part of the year.

I. nana.—A smooth herbaceous annual or biennial, only 3 in. high, native of Southern France and Italy. Leaves roundish, spoon-shaped, entire, rather fleshy. Flowers in June and July, purple.

Culture &c. as above. Increased by seeds.

I. odorata.—A native of Greece, annual, 6-12 in. high, with linear toothed leaves, ciliated at the base, dilated at the apex. Flowers in summer, white, sweet-scented, in racemes.

Culture &c. as above. Increased by seeds.

I. petræa.—A pretty alpine plant 3 in. high, with a flat cluster of pure white flowers, tinged with red in the centre, produced in summer.

Culture &c. as above. A well-drained moist position in the rockery is the most suitable place for this plant.

I. pinnata.—A pretty annual Candytuft 8-9 in. high, native of France, with

downy much-branched stems and stalked pinnately cut or divided leaves, with blunt lobes. The white sweet-scented flowers appear from spring to autumn, according to the period of seed sowing, borne in dense corymbose clusters. The obovate petals are sometimes tinged with violet on the margins.

Culture &c. as above. Increased by seeds.

I. Pruiti.—A Sicilian perennial 6 in. high, with smooth stems sub-shrubby at the base, resembling *I. tenoreana*. Leaves obovate, spoon-shaped, entire or somewhat toothed. Flowers in May and June, pure white, in compact heads or corymbs.

Culture &c. as above. Increased by seeds, cuttings, or layers.

I. saxatilis (*Rock Candytuft*).—This dwarf shrub, 3-6 in. high, native of S. Europe, is the commonest and perhaps most useful of all the evergreen Candytufts. It has linear, entire, somewhat fleshy, ciliated leaves, and corymbs or white flowers in spring and early summer.

Culture &c. as above. Increased by seeds, cuttings or layers.

I. semperflorens.—A handsome but somewhat tender evergreen 1-2 ft. high, native of Italy, Sicily &c. Leaves wedge-shaped or spoon-shaped, rather fleshy, blunt, entire, smooth and of a deep green. Flowers from October to May, pure white, large, sweet-scented, in large, dense corymbs.

Culture &c. as above. Owing to its tender nature, this species should be grown in only the warmest, sunniest, and most sheltered spots of the rockery or flower border. It may be increased by seeds, cuttings, or layers, and prefers a somewhat chalky soil.

I. sempervirens (*Evergreen Candytuft*).—A well-known plant 9-12 in. high, native of S. Europe. Leaves smooth, oblong, blunt, narrowed at the base. Flowers in spring and summer, pure white, in long racemes. The variety *garreuxiana* has somewhat smaller flowers borne on racemes which lengthen with age, and is less spreading in habit. *Superba* has a bushy habit and dense heads of white flowers; and *flore pleno* has double white flowers.

The Evergreen Candytuft and its varieties are excellent garden plants, suitable for almost any position, and

apparently quite proof against the bitterest winter.

Culture &c. as above. Increased by seeds, cuttings, or layers.

I. tenoreana.—A pretty perennial 3–6 in. high, native of S.W. Europe. Leaves somewhat fleshy, crenated, lower ones obovate, narrowed at the base and fringed with hairs; upper ones oblong linear. Flowers in early summer, white changing to purple, freely produced in umbellate heads.

Culture &c. as above. This species is liable to perish in severe winters on cold heavy soils. On well-drained sandy soil it does well, and is better treated as a biennial than a perennial. It is easily reproduced from seed sown as recommended above.

I. umbellata.—This is the well-known pretty annual Common Candytuft, 6–12 in. high, native of S. Europe. Leaves lance-shaped, pointed, lower ones serrated, upper ones entire. Flowers in spring and summer, very variable in colour, but usually purple in terminal umbels. *Atropurpurea* has dark crimson flowers; *carnea*, bluish or pale flesh-coloured; *nana purpurea*, dwarf, deep purple; *purpurea lilacina*, dwarf, lilac-purple. There are several other varieties mentioned in catalogues, chiefly distinguished by the colour of the flowers.

Culture and Propagation.—This group of Candytufts likes a rich soil, and produces the finest flowers in spring from seeds sown in autumn. General cultivation &c. as above for annuals.

I. violacea.—A dwarf annual, 3 in. high, with stalked, spoon-shaped, bluntly toothed or entire, ciliated leaves. Flowers in summer, purple, in umbellate corymbs.

Culture &c. as above. Increased by seeds.

HUTCHINSIA.—A genus with only one or two species of small and rather smooth annual herbs, having the lower leaves usually in rosettes, and pinnately lobed. Scapes several, ascending, leafy. Flowers sub-corymbose, small, white, on elongated bractless pedicels.

Culture and Propagation.—These are pretty plants for the rock garden, edges of borders &c., in sandy soil. They are raised from seed like other annuals, either in gentle heat about February and March, afterwards pricking the seedlings out and

hardening them off before placing in the open air at the end of May; or the seeds may be sown in the open border from April to the end of June for a succession of flowers.

H. alpina.—A pretty little alpine with shining green leaves, and clusters of small white flowers on stalks about 1 in. high.

Culture &c. as above.

H. petræa.—A more or less glabrous, erect, delicate annual, native of limestone rocks in Britain and Central and S. Europe, with lower leaves pinnate, and masses of minute white flowers.

Culture &c. as above.

IBERIDELLA.—A genus containing 6 species of rather pretty herbs or undershrubs, often branched and woody at the base, smooth, with alternate or opposite entire leaves, those of the stem often auricled, or cordately sagittate. Flowers racemose, white or rose.

I. rotundifolia.—A native of the European Alps, 3–6 in. high, spreading, densely tufted, with opposite, fleshy, broadly ovate leaves. Flowers in early summer, rosy-lilac, with a yellow eye, fragrant, about $\frac{1}{2}$ in. across, in erect, cylindrical, crowded racemes.

Culture and Propagation.—This species is adapted for the rock garden, and thrives in rather light sandy soil. It may be increased by seeds sown as soon as ripe in cold frames or in the open border in April and May. Or the plants may also be divided in early autumn, and cuttings of the shoots may be inserted in light sandy soil in a shaded border during the summer months.

TCHIHATCHEWIA.—A genus with only one species:—

T. isatidea.—A pretty Armenian rock-plant about a foot high, with very hairy oblong linear toothed leaves. The bright rosy-lilac and vanilla-scented flowers appear in May, and are borne in racemes about a foot across on thick fleshy stalks.

Culture and Propagation.—This plant flourishes in ordinary well-drained soil in the rock garden, and being a biennial should be raised from seeds sown in cold frames when ripe every year so as to keep up a stock of plants. The young plants may be transferred to the open air in spring, or in autumn if large enough.

PELTARIA.—A genus consisting of 3 species of tall glabrous perennial herbs, with entire leaves, the upper ones of which are cordate-sagittate at the base. Flowers more or less in corymbs, white. Pods large.

P. alliacea.—A pretty plant about 1 ft. high, native of E. Europe, and emitting a Garlic-like odour. The white flowers appear in June, followed by flat, smooth seed pods.

Culture and Propagation.—It will grow in any light soil, and may be increased by seeds or dividing the roots in the same way as recommended above for *Iberidella*.

ISATIS.—A genus of annual, biennial, or perennial smooth glaucous or downy herbs with entire leaves, those of the stems being sagittate. The flowers are usually yellow and borne in loose racemes. Sepals equal at the base. Stamens free. Fruit-pod a linear, oblong, ovate, roundish or wedge-shaped siliqua.

There are about 30 species in this genus, the best known being the native Dyer's Woad (*I. tinctoria*) so much in use by the ancient Britons for staining their bodies. With the exception of the species described below, the others are of no garden value.

I. glauca.—A beautiful perennial 3-4 ft. high, native of Smyrna. The light green furrowed stems are clothed with glaucous-green oblong lance-shaped leaves 6 in. long, having a whitish midrib. The small clear light yellow flowers appear in July, and are borne in immense numbers in large loose branched racemes which look very handsome and effective.

Culture and Propagation.—This species is not yet well known. It thrives in ordinary good garden soil in warm and sheltered positions in the flower border. Being a true perennial it may be increased by careful division in spring or early autumn; or by seeds sown in cold frames when ripe or in spring.

BOLEUM.—A genus with only one species here described:—

B. asperum.—An ornamental evergreen shrub, 6-12 in. high, native of France, covered with rather stiff hairs, and having alternate oblong-linear, entire leaves, the lower ones somewhat divided. Flowers in April, creamy yellow, in short erect and elongated racemes. Sepals

erect, equal at the base. The longer stamens united in pairs.

Culture and Propagation.—In severe winters this plant would probably require protection in northern parts of the country. It grows well in ordinary soil, and may be increased by seeds sown in a hotbed in spring, or in the open border in summer. Cuttings of the young shoots may also be rooted in light sandy soil under a hand-light during the summer months. The plants thus raised may be protected in cold frames until favourable weather in spring will permit of their being planted out.

GRAMBE (SEA KALE).—A genus with 16 species of herbs or undershrubs having thickened rootstocks and branched and glaucous smooth or hairy stems, furnished with large and often pinnately cut leaves. Flowers in elongated branched racemes or panicles.

Culture and Propagation.—The Sea Kale (*C. maritima*) is probably the best known representative of the genus, and its culture &c. is fully dealt with in the Vegetable section of this work at p. 1121. The species described below are the only ones at present known of any value as decorative plants. They are rather large and coarse growing, but when in full blossom are among the showiest and most attractive of flowering plants, chiefly on account of the immense numbers of blossoms they produce. They flourish in any garden soil and are more suitable for wild parts of the garden in open sunny spots, for association with such plants as *Heracleum giganteum*, p. 469, *Buphthalmum speciosum*, p. 511, &c. They ripen seeds freely and may be increased by that means sown out of doors or in cold frames as soon as ripe or in spring. The roots may also be divided at the latter season as growth is commencing.

C. cordifolia.—A vigorous and deep-rooting Caucasian perennial about 6 ft. high, with tufts of large radical heart-shaped lobed, wavy, and wrinkled leaves 12-18 in. wide. The white cross-shaped flowers are produced in immense numbers in June and early July, and are borne in much-branched panicles, which stand about 3 ft. above the foliage and are 4-6 ft. through, the branchlets spreading horizontally, or drooping at the base.

Culture &c. as above. Grows well in shade.

C. pinnatifida. — Another remarkable Caucasian perennial 4-5 ft. high, with pinnately divided and lobed leaves somewhat resembling those of a Turnip, only being much larger. The flowers appear at the same time as those of *C. cordifolia*, but the branching panicles are not quite so large, and the branchlets are rather ascending than horizontal and descending. It makes a good companion for *C. cordifolia* in the wilder parts of the garden.

Culture &c. as above.

MORISIA.—A genus with only one species here described:—

M. hypogæa.—A charming little perennial 2-3 in. high, native of the

Sardinian mountains. The smooth, deep and shining green leaves are more or less cut and lobed like those of Dandelions, and form dense tufts on the surface of the soil. The clear bright yellow flowers about an inch across, and with wedge-shaped petals, are produced in great profusion in April and May, just topping the foliage. The roundish one-seeded fruit pods are buried in the soil, but they do not ripen seeds freely in our climate.

Culture and Propagation.—This pretty plant flourishes in rich, damp, sandy loam in the flat border or in the rockery. It may be increased by seeds which should be sown when ripe, or failing these the plants may be divided in spring.

XII. RESEDACEÆ—Mignonette Order

Annual or perennial herbaceous plants, rarely shrubs, with alternate, entire, or pinnately divided leaves, and minute gland-like stipules. Flowers irregular, hermaphrodite, or rarely unisexual, borne in racemes or spikes, and furnished with bracts. Calyx persistent, 4-7-partite, often irregular, imbricate in bud. Petals 4-7, rarely 2 or none, deciduous or persistent, hypogynous or perigynous, entire or 3 to many partite. Disc hypogynous, conspicuous and glandular. Stamens usually many (3-40), perigynous or inserted on the disc, equal or unequal, free or connate. Ovary sessile or stalked with 2-6 connate carpels, lobed at the top, and open between the stigma-bearing lobes, with numerous ovules. Fruit dry and membranous, or succulent, opening at the apex; or apocarpous, with empty carpels surrounding a central placenta, or hooded and 1-seeded. Seeds kidney-shaped.

RESEDA (MIGNONETTE).—A genus containing about 26 species of erect or decumbent, smooth or hairy, annual or biennial herbs, with entire, lobed, or pinnatisect leaves, having gland-like stipules. Flowers racemose, with bracts. Calyx 4-7-parted. Petals 4-7, hypogynous, unequal, twice or many times cut. Torus almost sessile, urn-shaped, dilated behind. Stamens 10-40, inserted in the torus. Capsule indehiscent, 3-lobed at apex. Seeds numerous.

The following are the only species of any garden value, but *R. lutea* with greenish-yellow flowers and *R. luteola* (the Dyer's Rocket or Dyer's Weed) with small pale yellow flowers are to be met with in botanical collections.

R. alba.—A fine biennial about 2 ft., native of S. Europe. Leaves all pinnatifid or sometimes interruptedly pinnate, seg-

ments lance-shaped, smooth, rarely wavy. Flowers from May to September in dense, erect spikes, with white petals, brownish anthers, and a 5-6-parted calyx.

Culture and Propagation.—When given plenty of space to develop, this species makes a fine and effective border plant, and will grow in ordinary garden soil. Seeds may be sown in the open border in April and May, and the plants afterwards thinned out to about 1 ft. or 18 in. apart.

R. odorata (Mignonette).—This universal favourite is a native of N. Africa, Egypt &c., and has lance-shaped, blunt, entire or trifid leaves. Flowers out of doors from June to October, in loose racemes. Petals yellowish-white, finely cleft into several club-shaped filaments; anthers saffron-yellow, and calyx 6-parted. The variety *frutescens* is simply a shrubby

form of this species. There are many garden forms, among which may be mentioned 'Machet' with fine bold spikes of flowers in which the red-brown anthers are so conspicuous, 'Golden Machet,' 'Golden Queen,' 'Miles' Spiral,' 'Victoria,' 'Prince Bismarck,' 'White Diamond,' 'Parson's White' &c., all worth growing.

Culture and Propagation.—Were it not for the delicious fragrance of its flowers it is doubtful if the Mignonette would receive any attention at all in gardens. If sown in open patches in borders or beds, at the end of March or April till midsummer, in a few weeks the plants will be producing trusses of fragrant flowers, which may be cut freely. It is important to sow rather thinly, and even then it will be necessary to thin the plants severely, at the same time pinching out the tips of the strongest shoots on the plants left. This treatment will result in strong bushy plants.

If sown in the autumn, the plants will

survive mild winters, and will flower early in spring in the milder parts of the kingdom.

If required in pots, it is best to sow the seeds in spring in gentle heat, say a dozen seeds or so in each pot, afterwards thinning down to one, two, three, or five plants, according to the size of the pot. By judiciously pinching the points, one bushy plant will ultimately be found sufficient for a pot. The shrubby variety, *frutescens*, may be cultivated in pots for four or five years, by giving attention to pinching out the tips of the shoots so as to cause the side shoots to develop, and also by picking off the flowers as soon as they fade. The energy of the plant is thus not wasted in producing seeds, and is utilised for the development of more shoots. In this way quite large specimens can be obtained.

The soil for Mignonette in pots should be a rich and light sandy loam, with a little leaf mould.

XIII. CISTINEÆ—Rock Rose Order

Perennial herbs, shrubs, or undershrubs, often with viscid branches. Leaves entire, opposite or alternate, generally feather-veined, sometimes fan-veined. Stipules leafy, small or none. Flowers usually hermaphrodite, regular, solitary and terminal, or in scorpioid cymes; very fleeting; white, yellow, or red, never blue. Sepals 3-5, imbricate, the two outer ones small or absent, the three inner twisted in bud. Petals 5, rarely 3 or none, fleeting, often crumpled in bud. Stamens numerous, rarely few, hypogynous, free; ovary 1- or many-celled, with 3 stigmas. Fruit a 3-5 (rarely 10) valved capsule.

CISTUS (GUM CISTUS; Rock Rose). A genus containing about 20 well-defined species of beautiful shrubs, rarely undershrubs, often somewhat viscid, with opposite entire or somewhat toothed leaves without stipules. Flowers often beautiful, like Wild Roses, in terminal cymes or panicles, rarely sub-racemose or solitary. Petals 5, usually with a differently coloured blotch at the base. Stamens numerous.

Culture and Propagation.—It is somewhat unfortunate that lovely plants like the Rock Roses will grow well only in the warmest and most congenial parts of the British Islands. The flowers, though very fleeting individually, not lasting more than a day or so, are produced in such numbers in succession that the bushes always look full of bloom, and make a lovely picture. A rich, light, sandy soil,

and sheltered position facing south, are best, and a little extra protection in hard winters would probably save many a plant which now dies.

The Rock Roses may be increased by seeds, layers or cuttings. The latter should be about 3 or 4 in. long, and placed in sandy peat under handlights in early autumn. Layers may be made almost at any time. Seeds, however, give better plants. They should be sown early in spring in light soil under glass, and when the plants are 1-2 in. high, they may be shifted singly into small pots, and kept close and shaded in the frame for some time to get established. When hardened off by gradually allowing more air and sunshine, the plants may then be transferred to the outdoor garden in mild showery weather the following spring.

C. albidus.—A native of S.W. Europe, 2-5 ft. high, with stalkless, oblong elliptic, hoary or woolly leaves, somewhat 3-nerved. Flowers in June, 2-3 in. across, pale purple or rose, yellow at the base, petals overlapping.

Culture &c. as above.

C. candidissimus (*Rhodocistus bertholletianus*).—A shrub 4 ft. high, native of the Grand Canary Islands. Leaves ovate, elliptic, acute, covered with hoary wool, 3-nerved; stalks short, sheathing at the base, with hairy margins. Flowers in June, pale rose.

Culture &c. as above.

C. Clusii.—A native of Spain and Portugal, 2 ft. high. Leaves somewhat 3-nerved, linear, with revolute edges, hoary beneath. Flowers in summer, white, in heads, bracts hairy, broadly ovate, pointed, ciliate, deciduous, rather longer than the flower stalks. The true plant is rarely seen in cultivation, that which bears its name being usually *C. monspeliensis*.

Culture &c. as above.

C. creticus.—A native of Crete, 2 ft. high, with spoon-shaped, ovate leaves, wrinkled, covered with hairy wool, waved at the edges. Flowers in June, pale purple, yellow at the base. Sepals hairy. This is now regarded as a variety of *C. villosus*.

Culture &c. as above.

C. crispus.—A native of S.W. Europe, 2 ft. high. Leaves stalkless, linear, lance-shaped, waved and curled, 3-nerved, wrinkled, downy. Flowers in June and July, about 2½ in. across, almost stalkless, reddish-purple.

Culture &c. as above.

C. cupanianus.—A Sicilian plant, 2 ft. high. Leaves stalked, heart-shaped, ovate, wrinkled, net-veined, upper surface rough, lower covered with fasciated hairs, margins fringed. Flowers in June, white, with a spot of yellow at the base of each imbricating petal. Sepals hairy.

Culture &c. as above.

C. cyprius.—A native of Cyprus, 4-6 ft. high. Leaves stalked, oblong, lance-shaped, smooth above, covered with hoary wool beneath. Flowers in June, about 3 in. across, white, with a dark spot at the base of each petal.

Culture &c. as above.

C. heterophyllus.—An Algerian plant 2 ft. high, with ovate, lance-shaped, short-

stalked leaves, sheathing at the base, margins revolute. Flowers in June, large, red, yellow at the base, on hairy leafy stalks.

Culture &c. as above.

C. hirsutus.—A native of S.W. Europe, 2 ft. high, with unstalked, oblong, blunt, hairy leaves. Flowers in June, about 2 in. across, white, with a yellow mark at the base of the petals.

Culture &c. as above.

C. ladaniferus (*Gum Cistus*).—A native of Spain, 4 ft. high. Leaves almost stalkless, connate at the base, linear lance-shaped, 3-nerved, clammy above, woolly beneath and 4-5 in. long. Flowers in June, about 3 in. across, white, terminal, solitary. The variety *maculatus* has a dark blood-red blotch at the base of each of the white petals; while *albiflorus* has only a yellow stain at the base of the white petals.

Culture &c. as above.

C. latifolius.—A native of Barbary 3 ft. high. Leaves stalked, broadly heart-shaped, acute, with curled, wavy, toothed and ciliated margins. Flowers in May, white, with a yellow spot at the base of each petal.

Culture &c. as above.

C. laurifolius.—A native of S.W. Europe, 5-6 ft. high. Leaves stalked, ovate, lance-shaped, 3-nerved, smooth above, woolly beneath, stalks dilated and connate at the base. Flowers from June to August, about 3 in. across, white, with a yellow spot at the base of each petal, and borne in umbel-like clusters. There is a somewhat rare variety called *maculatus*, recognised by the deep purple-crimson blotch at the base of the white petals.

Culture &c. as above.

C. laxus.—A native of S. Europe, 3 ft. high. Leaves shortly stalked, ovate, lance-shaped, pointed, with wavy, somewhat toothed edges, upper ones hairy. Flowers in July, white, with yellow spots at the base. Flower stalks and sepals hairy.

Culture &c. as above.

C. longifolius.—A native of Spain and S. France. Leaves shortly stalked, oblong, lance-shaped, with waved and downy edges, veined beneath. Flowers in June, white, spotted with yellow at the base.

Culture &c. as above.

C. lusitanicus.—Probably a hybrid between *C. ladaniferus* and *C. monspeliensis*.

peleiensis, forming a dense compact bush 3-5 ft. high. It has deep green leaves and large white flowers with a purple blotch at the base of each petal.

Culture &c. as above.

C. monsperiensis.—A plant 4 ft. high, native of S. Europe, with linear, lance-shaped, stalkless, 3-nerved, clammy leaves, hairy on both surfaces. Flowers in July, 1-1½ in. across, white, borne in clusters of from 5 to 20 according to the vigour of the plant; petals imbricate and crenate with a yellowish blotch at the base. The variety *florentinus* has narrow, lance-shaped, wrinkled, almost stalkless leaves, veined beneath. The white flowers, yellow at the base and tipped with rose, are about 2 in. across and are produced somewhat earlier than those of the type.

Culture &c. as above.

C. oblongifolius.—A native of Spain, 4 ft. high, with hairy branches. Leaves shortly stalked, oblong lance-shaped, blunt, downy and waved at the edges, veined beneath. Flowers in June, white, concave, spotted with yellow at the base.

Culture &c. as above.

C. obtusifolius.—A Cretan species, 12-18 in. high, with a spreading habit. Leaves almost stalkless, tapering to the base, ovate-oblong, blunt, wrinkled, downy, margins somewhat toothed. Flowers in June, about 2 in. across, white, spotted with yellow at the base, several in a cluster.

Culture &c. as above.

C. parviflorus.—This is also a native of Crete and has a spreading habit like *C. obtusifolius*. The shoots are furnished with downy twisted leaves about an inch long, and the small pale rosy flowers, about 1 in. across, are borne in June in cymes or clusters at the ends of the shoots.

Culture &c. as above.

C. populifolius.—Native of S.W. Europe, 3-8 ft. high, with heart-shaped, pointed, wrinkled, smooth leaves, remarkable for having stalks 1½-2 in. long. Flowers in May and June, about 2 in. across, white, borne in cymose clusters; sepals clammy, bracts oblong.

Culture &c. as above.

C. psilosepalus.—A plant 2-3 ft. high, native country unknown. Leaves shortly stalked, oblong lance-shaped, 3-nerved, acute, waved at margins, somewhat toothed and ciliate, rather hairy. Flowers

from June to August, white with a yellow spot at the base of each broadly wedge-shaped petal. Sepals long pointed, smooth, shining, with ciliated edges.

Culture &c. as above.

C. purpureus.—A native of the Levant, 2-4 ft. high. Leaves oblong lance-shaped, pointed at each end, wrinkled, with short hairy sheathing stalks. Flowers in June, reddish-purple, with a dark purple spot at the base.

Culture &c. as above.

C. rotundifolius.—A native of South Europe, 1 ft. high. Leaves roundish ovate, blunt, flat, wrinkled, net-veined, with fascicled hairs on both sides, stalks furrowed, somewhat sheathing at the base. Flowers from June to September, purple spotted with yellow at the base. Sepals heart-shaped, hairy. Flower stalks very hairy. This is now considered to be a variety of *C. villosus*.

Culture &c. as above.

C. salvifolius.—Native of S. Europe, 2 ft. high, with many varieties. Leaves stalked, ovate, blunt, wrinkled, woolly beneath. Flowers from June to August, white, medium-sized, with woolly stalks.

The variety *corbariensis* (also known as *C. cordifolius*) is supposed to be a natural hybrid between this species and *C. populifolius*. It grows in the south of France to 2 ft. high or more. Leaves rather heart-shaped, ovate, pointed, with fringed margins, wrinkled on both surfaces, and very clammy. Flowers in June and July, 1½-2 in. across, white, with a yellow centre, each flower being on a long stalk.

Culture &c. as above.

C. vaginatus.—A native of Teneriffe, 2 ft. high. Leaves lance-shaped, acute, 3-nerved, hairy, net-veined beneath; stalks furrowed, dilated and sheathing at the base, with pilose margins. Flowers from April to June, deep rose.

Culture &c. as above.

C. villosus (*C. incanus*; *C. undulatus*). Native of S. Europe, 3 ft. high. Leaves stalked, roundish ovate, wrinkled, woolly and hairy; stalks furrowed, connate at the base. Flowers in June, large, reddish-purple, about 2½ in. across. The variety *canescens* is dwarfier and has oblong linear, bluntish, woolly, waved leaves, 3-nerved, without stalks and somewhat connate at the base. Flowers in May,

dark purple, tinged with blue, spotted with yellow at the base of each crenulate petal. Sepals downy.

Culture &c. as above.

HELIANTHEMUM (SUN ROSE).—

A genus of about 30 distinct species of annual or perennial herbs or shrubs, often prostrate, with opposite and alternate leaves. Flowers usually smaller than those of the Rock Roses, in secund racemes, sometimes corymbose, sometimes paniculate. Petals broad, 5 (in perfect flowers); stamens numerous, rarely few. Stigma capitate, or crestedly 3-lobed.

Culture and Propagation.—The Sun Roses grow freely in sandy loam, and are splendid plants for the rock garden, where they form compact masses of lovely flowers and foliage. The annual kinds are raised from seeds in the usual way in gentle heat about March, the seedlings being pricked off into light rich soil, and grown on until fit for the outdoor garden at the end of May. The perennials may also be increased in this way, but they are more easily obtained from cuttings, which root readily in sandy soil in a shady place during the summer months under a handlight.

H. atriplicifolium.—A woolly shrub 4 ft. high, native of Spain. Leaves stalked, broadly ovate, bluish, waved at the base, woolly on both sides. Flowers in June, large, yellow, on hairy stalks.

Culture &c. as above. Increased by seeds or cuttings.

H. canadense.—An erect, herbaceous, downy, Canadian species, 1 ft. high. Leaves oblong linear, margins usually revolute, woolly beneath. Flowers in summer, minute, crowded; stalks very short, 1-3-flowered.

Culture &c. as above.

H. carolinianum.—A native of the S. United States, 6-12 in. high, shrubby at the base. Leaves shortly stalked, lance-shaped, toothed, hairy. Flowers in May and June, yellow, 1 in. across.

Culture &c. as above.

H. formosum.—A hoary-branched Portuguese shrub, 4 ft. high. Leaves shortly stalked, obovate lance-shaped, covered with hairy wool, the younger ones hoary. Flowers in summer, large, yellow, spotted with black at the base;

stalks hairy. This has been also called a Cistus.

Culture &c. as above.

H. Fumanum.—An elegant Heath-like undershrub, native of S.W. Europe, with linear fleshy and slightly hairy leaves, and bright yellow flowers in June.

Culture &c. as above.

H. globulariæfolium.—An herbaceous species, about 9 in. high, native of Spain and Portugal. Lower leaves long-stalked, ovate-oblong, hairy, furrowed above; the upper ones stalkless, lanceolate. Flowers in summer, citron-yellow, black-spotted at the base of the petals and borne in dense racemes.

Culture &c. as above.

H. guttatum.—A native annual of stony places in Britain, Europe, North Africa, and W. Asia. Stem 6-12 in. high, with branches 2 or 3 times forked. Leaves 1-2 in. long, linear or obovate, or oblong lance-shaped, lower ones opposite without stipules, the upper ones alternate with stipules. Flowers from June to August, $\frac{1}{2}$ in. across, yellow with a red spot at the base of each wedge-shaped petal.

Culture &c. as above. Increased by seeds sown annually.

H. halimifolium.—A shrub 3-4 ft. high, native of Spain. Leaves downy, ovate lance-shaped, acute, wavy. Flowers in summer, large, bright yellow, slightly spotted at the base.

Culture &c. as above. Increased by seeds or cuttings.

H. italicum.—A European species only 3 in. high, with long, procumbent, hairy branches. Lower leaves stalked, ovate; upper ones almost stalkless, linear oblong. Flowers in summer, small, yellow; racemes simple, hairy.

Culture &c. as above.

H. lævipes.—A pretty shrub of S.W. Europe, 1 ft. high, with linear, needle-shaped leaves, and yellow flowers in summer. This species requires protection in severe winters.

Culture &c. as above.

H. lavandulæfolium.—A hoary branched undershrub 1 ft. high, from the Mediterranean region. Leaves oblong-linear, hoary, with revolute margins, under surface woolly. Flowers in summer, yellow, in crowded racemes.

Culture &c. as above.

H. ocymoides.—An undershrub 1-3 ft. high, native of S.W. Europe. Leaves stalkless, ovate, lance-shaped, blunt. Flowers in summer; petals yellow, crenate, with a dark base. *H. algarvensis*, *H. candidum* and *H. rugosum* are forms of this variable species.

Culture &c. as above.

H. polifolium (*H. pulverulentum*).—A rather rare British plant, but also distributed over Central and Southern Europe, and N. Africa. Leaves opposite, hoary and downy on both sides, with recurved edges. Flowers white, from May to July, marked with yellow at the base of the petals.

Culture &c. as above.

H. scoparium.—A Californian perennial about 3 in. high, with alternate, linear leaves without stipules. Flowers in May and June, small, yellow, in twos and threes at the ends of the branches; sepals 5, of which 3 are ovate-acute, and 2 awl-shaped.

Culture &c. as above.

H. umbellatum.—A perennial 9-18 in. high, with linear oblong leaves, recurved and ciliated at the edges, clammy when young. Flowers in June, pure white, in a whorled raceme ending in an umbel.

Culture &c. as above.

H. vineale.—A European shrubby evergreen, with variable obovate, ovate, or elliptic hairy leaves, and simple racemes of yellow flowers in summer.

Culture &c. as above.

H. vulgare (*H. surreianum*; *Cistus tomentosus*).—This is the Common Sun Rose of Britain, and from it have sprung most of the beautiful garden varieties. It is a shrubby procumbent plant 3-10 in. high, with opposite, oblong, stipulate leaves, hairy above, downy beneath. Flowers from June to September, more than 1 in. across, yellow, borne in loose racemes.

Among the many varieties may be mentioned: *barbatum*, with ovate or elliptic lance-shaped leaves, covered with white hairs; *hyssopifolium*, with flat, linear lance-shaped leaves, and saffron-coloured or coppery-red flowers, with also a double form of the latter; *macranthum*, with flat, ovate oblong, acutish leaves, smooth above, densely woolly beneath, and white flowers yellow at the base; *mutabile*, with pale rose-coloured flowers, yellow at the base, changing to white with age; and *ovalifolium* (or *serpyllifolium*), with roundish or ovate glossy green leaves, white beneath, and yellow flowers.

Culture &c. as above.

HUDSONIA.—A genus consisting of 3 species of distinct evergreen, Heath-like, tufted undershrubs, with small, needle-like, imbricated, downy leaves. Flowers small, yellow, numerous, crowded along the upper ends of the branches. Petals 5, small, fugacious. Stamens numerous.

Culture and Propagation.—The Hudsonias require a well-drained peaty or sandy soil, and should be grown in sheltered sunny spots. They do not grow well in pots, but may succeed better in the rockery or border where they would remain undisturbed at the roots. They may be increased by layers in summer, or by cuttings put under a glass and protected until the following spring, when they may be planted out in favourable weather.

H. ericoides.—A native of the Eastern United States, 1 ft. high, with needle-like leaves, and yellow flowers from May to July.

Culture &c. as above.

H. tomentosa.—A hoary and downy N. American plant, with oval or narrowly oblong, short, close-pressed and imbricated leaves, and sessile or short-stalked yellow flowers in early summer.

Culture &c. as above.

XIV. VIOLARIEÆ—Viola and Pansy Order

Herbs or shrubs with alternate, rarely opposite, simple, entire, or rarely lobed leaves, and small or leafy stipules, which are usually deciduous in shrubby species. Flowers usually hermaphrodite, axillary, regular or irregular, solitary or in racemose or paniced cymes, 2-bracteolate. Sepals 5, often persistent, equal or unequal, imbricate in bud, and usually elongated into a spur at the

base. Petals 5, hypogynous or slightly perigynous, equal or unequal, imbricate or often contorted in bud. Stamens 5, hypogynous, or slightly perigynous; filaments dilated, with connectives produced beyond the anthers. Ovary sessile, free, 1-celled, many-seeded. Fruit a 3-valved, dehiscent capsule, rarely an indehiscent berry.

VIOLA (VIOLET; PANSY; HEARTSEASE).—A genus containing over 200 species according to some authors, but reduced to about 100 by Bentham and Hooker, mostly pretty perennial herbs, rarely shrubs, with alternate leaves, and persistent, often leafy, stipules. Flower stalks axillary, 1- rarely 2- flowered. Sepals almost equal, produced at the base. Petals spreading, the lower ones often larger, spurred or saccate at the base. Anthers connate and produced at the apex, the 2 lower stamens often spurred at the base.

Violas often produce two kinds of flowers—the large petaloid ones, which appear first and often yield no seed; and the smaller petaloid, or non-petaloid ones, which appear later, and produce seed freely, being often fertilised in bud, when they are said to be ‘cleistogamous.’

Culture and Propagation.—Generally speaking Violas of all kinds are among the most easily grown plants in gardens. They delight in a rich, moist, sandy soil but dislike stagnant water at the roots and a position that is never shaded from the scorching rays of the summer sun. As most of them grow naturally in banks, copses, more or less marshy places, pastures &c., where they are to a certain extent shaded by the overhanging branches of trees, or by the leaves of the surrounding vegetation, they thrive under somewhat similar conditions in a cultivated state. The cultivation of Sweet Violas (*V. odorata*) and Pansies (*V. tricolor*) is dealt with under their respective species.

Violas are easily increased by seeds, cuttings, or division. If desired to flower the same year, say in autumn, the seeds should be sown in spring in the open border during April and May in light rich soil. If the flowers are wanted in spring, the seeds may be sown in August or September so that the seedlings will be strong and well-established for the winter months. The seedlings may be either pricked out and transplanted once or twice to induce the development of masses of fibrous roots, or they may be

thinned out in the spot where the seeds have been sown. Cuttings may be taken early in April and inserted in a prepared patch of fine sandy soil in a shady border, and protected by handlights or frames, until well rooted. By September they may be transplanted to their permanent quarters, and will give a good supply of bloom the following spring. If planted in beds by themselves they should not be nearer than 1 ft. apart so as to admit of hoeing. After flowering the plants may be lifted and carefully divided into as many pieces as possible, and replanted, each rooted portion making a good tuft for next season's flowering.

V. altaica.—A native of the Altaian Mts. with hard creeping slender roots. Leaves oval, with sharply toothed wedge-shaped stipules. Flowers from March to June, yellow, large, with acute toothed sepals, and an urn-shaped stigma.

Culture &c. as above.

V. arenaria.—A somewhat rare British species, compact in growth, and covered with a hoary down, the whole plant 2-6 in. across. Leaves roundish, ovate, blunt. Flowers from April to June, with broad pale blue petals, and a short spur.

Culture &c. as above.

V. biflora.—A pretty little Violet 3-4 in. high, widely distributed throughout Asia, Europe, and America. Leaves kidney-shaped, serrated, smooth, with ovate stipules. Flowers from April to June, small, yellow, the lip streaked with black, usually in pairs, petals smooth; spur very short, sepals linear, stigma bifid.

Culture &c. as above. This curious little Violet requires well-drained sandy peat and loam, and may be increased by dividing the roots in early autumn or in spring, and also by seeds sown as above. It dislikes sunny places.

V. blanda.—An American species with creeping rootstock, and roundish, heart-shaped or kidney-shaped, slightly downy leaves. Flowers in early spring, white, small, faintly scented; petals almost beard-

less, the side ones veined with lilac; spur short.

Culture &c. as above.

V. calcarata.—A very variable fibrous-rooted species, native of the Austrian Mountains. Leaves roundish or spoon-shaped, crenate, stipules palmately cut or trifid. Flowers in early summer, light blue or white; sepals oblong, glandularly toothed; spur awl-shaped, longer than the calyx. The variety *flava* or *Zoyssii* has yellow flowers; *albiflora* has large white flowers, and *Halleri* large blue ones.

Culture &c. as above for *V. biflora*.

V. canadensis.—A free-growing N. American species 6-9 in. high, with alternate broadly heart-shaped, pointed, serrate leaves. Flowers from May to August, whitish inside, the upper petals mostly tinged with violet beneath, the side ones bearded; spur very short.

Culture &c. as above. A very suitable plant for sloping banks or the rockery. Easily increased by dividing the roots in spring or early autumn; also by seeds and cuttings.

V. canina (Dog Violet).—A very variable species, native of British pastures and banks. Leaves 1-3 in. across, long-stalked, crenate serrate, varying from broadly ovate heart-shaped to lanceolate. Flowers $\frac{1}{2}$ -1 $\frac{1}{4}$ in. across, from April to August, blue, lilac, grey, or white; sepals narrow pointed; spur blunt; style club-shaped, hooked. The variety *lactea* is a very slender plant with ovate lance-shaped leaves, rounded or wedge-shaped at the base, and with narrow grey petals. *Perricæfolia* has long rootstocks with runners, leaves oblong lance-shaped, and white or lilac flowers with a very short spur. The variety *alba*, as the name indicates, has white flowers.

Culture &c. as above.

V. capillaris.—A Chilean species with many tufted, decumbent stems. Leaves ovate-oblong, blunt at the base, slightly acute at the apex, with glandular teeth on the margins. Flowers from May to August, pale blue, side petals densely bearded, spur short, blunt, greenish.

Culture &c. as above.

V. cornuta.—A tufted, fibrous-rooted, ornamental species, native of the Pyrenees and Switzerland. Leaves heart-shaped, ovate, crenate, ciliated, with obliquely heart-shaped, toothed, ciliated stipules. Flowers from May to July, pale blue;

sepals and spur awl-shaped, the latter elongated and abrupt at the base. The variety *alba* has white flowers which look pretty nestling among the masses of deep green leaves.

Culture &c. as above. This species and its variety look pretty in masses in shaded parts of the rockery, or on banks or slopes, and although the flowers are odourless they are effective. Best increased by sowing seeds annually.

V. cucullata.—A very variable free flowering species with very scaly rootstocks, native of N. America. Leaves long-stalked, erect, more or less kidney- or heart-shaped, with a broad sinus, smooth or slightly downy, bluntly serrated. Flowers in early summer on scapes 3-10 in. high, deep or pale violet-blue or purple, sometimes almost white or variegated with white as in the variety called *variegata*; the side petals and often the lower ones bearded; spur short, thick. The variety *palmata* has leaves 3-7-parted or cleft, or the earlier ones entire on the same plant.

Culture &c. as above. Increased readily by dividing the roots early in autumn or in spring.

V. declinata.—A pretty Transylvanian Viola about 6 in. high with ovate and bluntly toothed leaves, and large flowers of a rich bright purple, with deeper markings near the yellow centre.

Culture &c. as above.

V. delphinifolia.—An interesting species, native of the Missourian prairies. Leaves pedately 7-9-parted, with narrow 2-3-cleft segments, reminding one of Larkspur foliage; stipules ovate lance-shaped, nearly entire. Flowers in spring, beautiful sky-blue, the 2 upper petals downy, the lower ones notched at the end; spur pouched, short.

Culture &c. as above.

V. hederacea (Erpetion hederaceum; E. reniforme).—A tufted Australian species, with roundish, kidney-shaped or spoon-shaped leaves, $\frac{1}{2}$ to 1 in. broad, entire or toothed. Flowers in summer, blue, rarely white, small; petals smooth, or the side ones slightly downy inside; spur reduced to a slight concavity. The variety *grandiflora* is an improved form.

Culture &c. as above. This pretty species requires protection in winter. It should be propagated by cuttings in autumn, kept under glass in winter, and

planted out at the end of May or beginning of June.

V. heterophylla. — A pretty alpine Violet with a dwarf compact habit. The leaves are narrowly lance-shaped and toothed, and of a bright green, while the large blue flowers are produced in great abundance in early summer.

Culture &c. as above.

V. hirta. — A tufted, hairy British plant, near *V. odorata* but with narrower and more triangular leaves, with deeper crenatures, and a shallower sinus. Flowers from April to June, faintly scented or not; spur long and hooked. The variety *calcareea* is a dwarf starved form with narrower petals.

Culture &c. as above.

V. lanceolata. — A N. American species with a creeping rootstock, and lance-shaped, blunt, erect leaves tapering into long, margined stalks. Flowers in early spring, white, small; petals beardless, the lower ones veined with lilac.

Culture &c. as above.

V. montana. — A simple-stemmed, erect species 1 ft. high, native of Europe, Siberia &c. Lower leaves heart-shaped, upper ones ovate, acute, stalks margined; stipules oblong toothed or incised. Flowers from May to July, white, becoming bluish; spur conical, straight, greenish; stigma papillose, slightly reflexed. The variety *Ruppilii* has heart-shaped or lance-shaped leaves and procumbent stems.

Culture &c. as above.

V. munbyana. — A pretty free-flowering, vigorous species, native of Algiers. Leaves ovate-heart-shaped, bluntly crenate, smooth or slightly hairy on the edges. Flowers from February to May, and also during the autumn months in favourable seasons, large, violet or yellow, produced well above the foliage; spur straight, nearly twice as long as calyx. The variety *lutea* has yellow flowers which are faintly striped with purple at the base.

Culture &c. as above. Although a perennial it is on the whole better to treat this species and its variety as a biennial, by raising seeds annually as recommended above.

V. odorata (*Sweet Violet*). — This well-known plant is wild in British copses and banks, and is also distributed over Europe, N. Africa, N. and W. Asia

to the Himalayas. Rootstock short, scarred, with long runners. Leaves deeply heart-shaped at the base, sinus closed; stipules glandular; stalks with deflexed hairs. Flowers from March to May, sweet-scented, blue, white, or reddish-purple; the side petals with or without a tuft of hairs; spur short, blunt. Anthers linear oblong.

The dwarf and distinct variety *alba* has white flowers; *pallida plena* (the Neapolitan or Parma Violet) very sweet-scented, double, pale lavender flowers; *permixta* (probably a hybrid with *V. hirta*) pale, scentless flowers, runners not rooting; and *sepincola* (also probably a hybrid) flowers dark, scentless, plant more hairy, with rooting runners. *Sulphurea* is a new variety of Sweet Violet, with shining deep green leaves, and lemon-yellow flowers, with a deeper yellow shade in the centre, and a pale violet spur behind. There are many garden varieties, among which the following are best known: — *argentiflora*, purplish-white, fragrant; *Comte Brasza*, white, double, sweet-scented; *Czar*, very large, single, blue and fragrant; *White Czar*, a fine white form of the preceding; *Admiral Avellan*; *La Grosse Bleue*; *Californica*; *Princess of Wales*; *Belle de Chatenay*, strong double white or rose-white; *La France*; *Luxonne*, strong, beautiful, paler than the *Czar* but larger, much grown in the S. of France; *Lady Hume Campbell*; *Marie Louise*, lavender blue and white, very large, sweet-scented and free-flowering; *Queen of Violets*, double white, flushed pink; *Victoria Regina*, large double blue, sweet-scented; *Russian*, an old free-growing large single blue variety; *Wellsiana*; *Wilson*; *La Violette des Quatre Saisons*, flowers throughout the autumn, winter and spring, and is a great favourite with Parisians.

Culture and Propagation. — In the open border Sweet Violets delight in a rich and fairly heavy soil. They require a little shelter, and the best and most natural is that given by the surrounding plants, among which the air circulates freely. Away from brick walls, and on banks at the base of a hedge, facing north or north-west, is perhaps the best place for violets. Failing such natural positions the plants will of course do well in the ordinary flat border, not facing due south.

During the summer months a mulching of short rotten manure or the

remnants of spent mushroom beds is beneficial. It not only prevents the moisture in the soil from evaporating too quickly, but also stifles the weeds, if any. A gentle watering in the cool of the summer evening is also most refreshing to the plants.

If the plants are too much crowded, or in too hot a position, they are liable to be attacked in the first case by green-fly, and in the second by red-spider. Both these pests, however, may be kept at bay by frequent use of the syringe, using clean hot water (say 80°-120° F.). Dusting with fine sulphur is a good remedy, but it makes the plants very unsightly.

Forcing Sweet Violets.—Where cold frames exist in any garden, Sweet Violets may with advantage be grown in them for flowering during the winter and early spring. The plants should be lifted about the end of September from the open ground and planted in rich soil in the frames, with the foliage as near the glass as possible. The plants should be thoroughly watered in, and kept close, that is, no air, or very little, should be admitted for about a week or ten days after planting, so that the roots may more quickly take a hold of the new soil. After this and throughout the winter, on favourable days, plenty of air may be given, and the lights may even be removed altogether on mild sunny days. Winter fogs are very injurious to both leaves and flowers, the former damping off, the latter remaining undeveloped.

Most of the varieties named above are suitable for growing in frames, but Marie Louise, Comte Brazza, and the Neapolitan (or Parma) Violets are the best.

Sweet Violets are easily increased by simply dividing the crowns after flowering, and planting about 9 in. apart in rich soil, in a somewhat shaded place. Fine flowering plants may also be obtained from seed, which should be sown as soon as ripe, or during the spring months as recommended above for the species in general, p. 228.

V. palustris.—A native of the swamps and bogs in Great Britain and Ireland, chiefly in the northern parts. Rootstock white scaly, creeping. Leaves kidney- or heart-shaped, slightly crenate, with gland-like stipules. Flowers from April to July, $\frac{1}{2}$ in. across, white or lilac, scentless; side petals almost smooth; spur short, blunt.

Culture &c. as above for the species in general, p. 228.

V. pedata (*V. flabellifolia*; *V. flabellata*).—*Bird's Foot Violet.*—A beautiful N. American species with a thick rootstock. Leaves pedately divided, something like a bird's foot, with linear lance-shaped leaflets, entire or deeply 3-toothed at apex, sometimes very narrow and much cut; stipules ciliated. Flowers in May and June, usually bright blue, sometimes pale or white, large; petals smooth; spur very short; stigma large and thick, margined, obliquely truncate.

The variety *atropurpurea* has incised, wedge-shaped leaf segments, dark purple flowers and a downy pistil. *Bicolor* is a rare and handsome variety, with the 2 upper petals deep velvety violet. It does not grow equally well in all places, and requires special care. The form called *alba* has white flowers.

Culture &c. as above for the species in general, p. 228.

V. pedunculata.—A Californian species with rhomboid-ovate leaves about 1 in. long, rather thick, coarsely and bluntly toothed, and abruptly narrowed at the base. Flowers in spring, large, deep yellow; petals broadly obovate, the 2 upper ones conspicuously clawed, the side ones bearded at the base; spur very short.

Culture &c. as above for the species in general, p. 228.

V. pinnata.—A species from the mountains of S. Europe and Siberia. Leaves deeply divided into 4 or 5 segments, each 3-parted or pinnatifid, jagged and very narrow. Flowers in early summer, pale blue, with darker veins, the 2 side-petals bearded; sepals ovate; spur broad, nearly straight.

Culture &c. as above, p. 228.

V. præmorsa.—A North American species, usually densely hairy, with short erect stems. Leaves ovate lance-shaped, repandly toothed or almost entire; stipules entire. Flowers in spring, rather large, yellow; lower petal veined with brown, emarginate; spur very short.

Culture &c. as above, p. 228.

V. pubescens.—A softly downy species 6-12 in. high, native of N. America. Stems simple erect, naked below, 2-4 leaved above. Leaves broadly heart-shaped, toothed, somewhat pointed;

stipules large, ovate, entire or serrated at the top. Flowers in spring and early summer, yellow, lower petal streaked with purple; sepals oblong lance-shaped; spur very short; stigma with 2 tufts of hair.

The variety *eriocarpa* is much taller, stouter growing, and more downy than the species, and has woolly seed pods.

Culture &c. as above.

V. pyrolæfolia.—A Patagonian species, with ovate or more or less heart-shaped leaves, with stipules fringed at the apex. Flowers in winter (January), yellow; petals densely bearded within; sepals pointed; spur short, blunt.

Culture &c. as above.

V. rostrata.—A native of N. America, 4-6 in. high, with roundish heart-shaped, serrate leaves, upper ones acute; stipules large, lance-shaped, fringed, toothed. Flowers in early summer, dingy purple or lavender, with darker streaks. Petals smooth; spur slender, rather acute, $\frac{1}{2}$ in. long.

Culture &c. as above.

V. rothomagensis.—A free-growing hairy species, native of Belgium, France, and Sicily, with rather spindle-shaped roots, and zigzag branching stems. Leaves ovate, the lower ones somewhat heart-shaped, crenate, fringed, stipules pinnatifid, rather lyrate; flowers from April to August, bright blue, the side petals and lip striped with black; spur tubular, blunt, shorter than the sepals; bracts near the flower, lance-shaped, with a tooth on each side.

Culture &c. as above. This species requires a warm, sheltered position. It is sometimes called the Rouen Violet, and is best raised from seeds sown annually as recommended above.

V. rotundifolia.—An American species with a creeping rootstock. Leaves shining, roundish ovate, heart-shaped, slightly crenate, increasing from 1 in. broad at flowering time to 3 or 4 inches. Flowers in early spring, yellow; side petals bearded and lined with brown; spur very short.

Culture &c. as above.

V. sagittata (*V. dentata*).—A smooth or hairy species from N. America. Leaves with small and margined or naked stalks, varying from oblong heart-shaped to hastate, sagittate, oblong lance-shaped, or ovate, toothed. Flowers in spring and early summer, rather large, purplish-

blue; usually the side, but sometimes all the petals, bearded; spur short and thick; stigma bearded. The variety *emarginata* has almost triangular leaves, lacerate-toothed near the base; petals emarginate or with 2 teeth.

Culture &c. as above.

V. Selkirki (*V. umbrosa*).—A small delicate fibrous-rooted species, native of North America. Leaves roundly heart-shaped, crenate, with a deep, narrow sinus, and minutely hairy above. Flowers in spring and early summer, pale violet; spur very large, nearly as long as petals, thickened at the end.

Culture &c. as above.

V. striata.—A North American species with ascending angular stems, 6-12 in. high. Leaves heart-shaped, finely serrated, often acute; stipules large, oblong lance-shaped, fringed with strong teeth. Flowers from April to October, cream-coloured or white; side petals bearded, the lower ones lined with purple; spur rather thick, much shorter than the petals; stigma beaked.

Culture &c. as above.

V. suavis (*Russian Violet*).—A native of Tauria, with long creeping and rooting stolons. Leaves downy, kidney- or heart-shaped, crenate. Flowers from March to May, pale blue, white at the base, sweet-scented; sepals blunt; four upper petals narrowest, the lower one emarginate, the 2 side ones with a hairy line; stigma hooked, naked.

Culture &c. as above.

V. sylvestris (*Wood Violet*).—A native of the copses and woods of Britain. Rootstock very short. Plant smooth with leaves in a rosette, broadly ovate heart-shaped, stipules lance-shaped acute, fimbriate or toothed. Flowers from March to July, bluish-purple or lilac; base of sepals much produced in fruit; spur short, broad, compressed, furrowed, usually pale. The variety *reichenbachiana* has flowers smaller, paler and earlier; spurs longer, fruiting sepals scarcely produced. The variety *rivimiana* has the lower leaves as broad as long; the upper ones a little narrower than long. Flowers later in summer than the type, bluish-purple or lilac, scentless; petals obovate oblong, the lowest much broader than the others; flower-stalks long, with 2 small bracts. There is also a variety having

pure white flowers (*alba*), and another rarely seen with rose-coloured ones (*rubra*).

Culture &c. as above. Easily increased by seeds or division of the roots.

V. tricolor (*Heartsease and Pansy*).

This is the wild plant from which the well-known Heartsease and Pansy are supposed to have originated, although some believe that these popular flowers are descended from *V. altaica*. The wild Pansy is a native of the pastures, banks and waste places in the British Islands, and is also found in such diverse places as Arctic Europe, N. Africa, N. and W. Asia to Siberia and N.W. India. Stems 4-8 in. high, branched, erect or ascending, angled, flexuous. Leaves, with long stalks, ovate oblong or lance-shaped, crenate, 1-1½ in. long, lyrate, coarsely and remotely crenate-serrate; stipules very large, pinnatifid; lobes spreading like a fan, linear or oblong obtuse, the middle one largest. Flowers from May to September, ½-1¼ in. across, with purple, whitish, or golden-yellow petals, sometimes parti-coloured; spur thick, blunt; stigma capitate, hollowed. The variety *arvensis* has white or yellowish flowers, petals usually shorter than the sepals; *Curtisi* has a branching rootstock, with runners, and blue, purple, or yellow flowers, with spreading petals; and *lutea* (known as the Mountain Vine) has a branched rootstock, short stem with underground runners, and blue, purple, or yellow flowers, with spreading petals much longer than the sepals.

Culture &c. as below.

HYBRID PANSIES

The natural species and its varieties are utterly eclipsed by the vast number of beautiful forms which have been raised from them by British and Continental gardeners. Among the numerous cultivated varieties are many in which the flowers have only one—or almost one colour, chiefly white, yellow, rose, copper, violet, blue in various shades, chestnut, purple, intense velvety black &c. Others, and more numerous, have various colours on white or yellow grounds; others again have copper, old gold, or bronzy flowers with various shades. Then there are veined, striped, blotched, variegated, flamed, bordered and zoned flowers, washed and shaded with various colours in all sorts of ways, sometimes giving the

flowers a most singular appearance. Indeed the range and combination of colour in Pansies is truly infinite, and where seedlings are raised regularly every year, new combinations, colours, and developments take place.

Pansies have come under the arbitrary rule of the florist, and he has divided them into three main sections as follows:—

(1) *English or Show Varieties*.—

These are subdivided into white grounds, yellow grounds, and selfs. The flowers of 'white ground' Pansies have a large dense, dark blotch in the centre, with a ring or band of white, cream or straw colour around it, and this ring may be edged with blue, or various shades of purple. In the 'yellow grounds,' the ring is a pale or deep gold colour edged with various shades of bronze, maroon &c. The 'selfs' must be clear decided colours, of one shade, and should have a dark well-defined blotch under the eye or centre.

(2) *Belgian or Fancy Varieties*.—

These are usually very large and richly coloured, and should have a deep coloured blotch covering almost the whole of the bottom petal or lip and contiguous parts of the side petals. The remaining portion of the flower may be any of the numerous shades referred to, but should always be so pale that the colour of the lower petal is much denser and decidedly conspicuous in comparison.

(3) *Tufted Pansies* is the modern name, and certainly an appropriate one, for Bedding Pansies and Violas, and many simply call them Violas—a pretty name. They are hybrids between *V. cornuta* and various garden-pansies, *V. cornuta* being the seed bearer. If the reverse cross is made, a more or less ordinary Pansy will result.

Violas or Tufted Pansies generally have a dwarf, close, bushy habit, and beautiful flowers—usually self-coloured—much smaller than the ordinary Pansy. In beds by themselves, or associated with other plants as a kind of floral carpet, Violas make a charming picture.

Culture and Propagation.—Pansies germinate readily from seeds, and may be sown in the open border or in shallow pans or boxes in July and August, in rich sandy soil with plenty of leaf mould in it. In the open border the seedlings may be thinned to about 6 in. apart, and

by the end of September they will be large and strong enough to transfer to the positions in which they are required to bloom the following spring. From a packet of choice mixed seed, plants with the most gorgeous flowers may be obtained, and if there are any particularly fine, it will be easy to perpetuate them by means of cuttings. To obtain a good supply of these, the plant may have its branches pegged down, and as quickly as the shoots are produced they may be detached.

Cuttings may also be inserted in July and August, and by the first week in October the plants will be ready for their permanent positions.

Provided the plants are grown in a rich sandy loam, well-manured, Pansies and Violas are the easiest of plants to grow. Some thousands of Pansies and Violas are sold every spring in the London markets neatly bound in hay enclosing a ball of soil round the roots. The regular trade done rather indicates that all—or at least the majority—of the plants thus sold perish during the year. The reason probably is that Pansies and Violas do not really care to be disturbed in spring, just about the period when the flowers are draining the plant of its reserve material for the production of seeds. The flowers trying to carry out the natural laws of seeding, and the injured roots trying to re-establish themselves, the plant as a whole becomes more or less exhausted, and naturally succumbs in due course.

Pansies and Violas for Spring Bedding.—Too much importance can scarcely be attached to these charming plants for decorating flower-beds and borders during the spring and early summer months, and right up till the autumn even. If the very best results are required Pansies and Violas should be planted about the end of September, or as soon as ever the beds and borders have been cleared of the usual stock of summer bedding plants. The soil should be well dug and manured, and if light or heavy should be improved according to the recommendations given at p. 63 in the chapter on Soils. Whole beds may be planted with a variety of one colour alone, or two or three distinct varieties and colours may be used in an agreeable combination. The best contrasts are obtained by the juxtaposition of the primary colours, such as reds, blues, and

yellows, and when intermediate shades are used care should be taken so that one colour has an effect upon another. For example, yellow looks colder with blue than with red, but blue is more effective with yellow than with white, and so on. As a rule the section known as 'Violas' or 'Tufted Pansies' are most effective for bedding purposes, and the colours chosen should always be clear and well defined, not 'washy' or indefinite, as if one colour had run into another before it had got dry.

The following is a list of some of the best Pansies and Violas arranged in the three main shades of colour, but any one can probably raise equally as good from choice seeds. There are many intermediate shades of colour, but as a rule the varieties with clear and well-defined self or uniform colours look best for bedding purposes.

WHITE-FLOWERED VIOLAS

Accushla, Blanche, Countess of Hopetoun, Countess of Wharnclyffe, Dr. Sculthorpe, Marchioness, Mary Scott, Mary Stuart, Niphetos, President, Sylvia.

YELLOW-FLOWERED VIOLAS

A. J. Rowberry, Ardwell Gem, Bullion, Duchess of Fife, Fanny Emmeline, George Lord, Golden Bee, Golden Boy, Goldfinch, Henry IV., Kitty Hay, Kitty Whitworth, Lemon Queen, Lord Elcho, Molly Pope, Mrs. Greenwood, Nellie M. Brown, Pembroke, Renown, Sir Robert Peel, Wonder.

BLUE AND PURPLE-FLOWERED VIOLAS

Acme, Blue Gown, Border Witch, Britannia, Commander, Councillor W. Waters, Dorothy Tennant, Ethelinde, J. B. Riding, John Shires, Magnificent, Mrs. Grant, Mrs. H. Bellamy, Olivetta, The Mearns, William Haig.

V. variegata.—A native of Dahuria, with rather hard subdivided roots. Leaves heart-shaped-ovate or roundish, violaceous beneath, obscurely green above, white at the veins, and rather hairy; stipules lance-shaped, toothed. Flowers in May and June, pale violet; spur cylindrical, straight, as long as the sepals.

Culture &c. as above, p. 228.

HYMENANTHERA.—A genus containing about 4 species of rigid shrubs on

small trees, with alternate, sometimes clustered, often small, entire or toothed leaves without stipules. Flowers axillary, small, sometimes polygamous, solitary or in clusters.

H. crassifolia.—An ornamental shrub 2–4 ft. high, native of New Zealand, somewhat resembling a white-berried Cotoneaster when in fruit. Leaves alternate or tufted, linear spoon-shaped, entire, about $\frac{1}{2}$ in. long. Flowers about March, yellowish, small, followed by masses of white shining berries, $\frac{1}{4}$ in. long, oblong obtuse.

Culture and Propagation.—This is the only species of any note in cultivation. It flourishes in a mixture of sandy peat and loam, and may be increased by cuttings put in sandy soil under a bell glass during the late summer months and protected until the following spring.

The plant is quite hardy as far north as Cheshire, and perhaps still further north. It is not only an excellent plant for the garden, but is also remarkable for its shrubby habit, so unlike what is usually associated with its relatives, the Pansies and Violas.

XV. BIXINEÆ

Trees or shrubs with alternate, simple, toothed, or more rarely entire leathery leaves, often marked with transparent dots. Stipules caducous or none. Flower stalks axillary, many-flowered. Flowers regular, hermaphrodite or unisexual. Sepals 2–6, often 4–5, slightly cohering at the base. Petals none or equal in number to the sepals, or numerous, and imbricate or contorted in bud, deciduous. Stamens hypogynous, of the same number as the petals, or some multiple of them, dehiscing by a pore at the apex. Ovary 1- or more celled, with several more or less distinct stigmas. Fruit either fleshy and indehiscent, or capsular, with 4 or 5 valves, the centre filled with a thin pulp. Seeds numerous.

This order contains about 160 species, mostly natives of warm regions and not hardy enough for our climate. The following are the only representatives grown out of doors in the British Isles.

AZARA.—A genus of about 12 species of ornamental evergreen trees or shrubs, with entire or serrate leaves, often with conspicuous stipules. Flowers hermaphrodite, borne in clusters, or shortly corymbose or almost spicate. Sepals 4, subvalvate, or 5–6 imbricated. Petals none. Stamens numerous (except in *A. microphylla*).

Culture and Propagation.—The Azaras thrive in well-drained, rich, sandy loam, and may be increased from cuttings of the ripened shoots placed in sandy soil under a glass and in gentle bottom heat in late summer and autumn.

In the southern counties and the milder parts of Ireland and Scotland the Azaras are hardy, but in more unfavourable parts protection may be required in severe winters. Trained against walls with a southern aspect, or grown as bushes, they are ornamental. All the plants are natives of Chili, and those

described below are hardy against south walls in sheltered situations near London.

A. dentata.—A shrub 12 ft. high, with ovate, serrate, roughish leaves, woolly beneath; stipules leafy, unequal in size. Flowers in June, yellow, in few-flowered sessile corymbs.

Culture &c. as above.

A. Gilliesi.—A beautiful shrub 15 ft. high, with reddish-tinted branches and large, smooth, ovate, coarsely toothed leaves, like Holly. Flowers in autumn, bright yellow, in axillary densely packed panicles.

Culture &c. as above.

A. integrifolia.—About 18 ft. high, with obovate or oblong, entire, smooth leaves; stipules equal, persistent. Flowers in autumn, yellow, fragrant, on short axillary spikes. There is a rare variegated form.

Culture &c. as above.

A. microphylla.—An ornamental shrub 12 ft. high, with small obovate obtuse, dark shining green leaves, in opposite rows up the stem. Flowers in autumn, greenish, corymbose, followed by numerous small orange-coloured berries.

Culture &c. as above. This is probably the best known species.

IDESIA.—A genus with only one species, the description of which is given below with the generic characters.

I. polycarpa (*Flacourtia japonica*).—An ornamental tree native of China and Japan, where it assumes very large proportions, but is much smaller in cultivation. It has large and rather heart-shaped 5-nerved alternate leaves with serrated margins, and long racemes of rather large yellowish flowers borne in long drooping racemes at the ends of the branches. The male flowers are borne on one plant, the females on another. There are 5 (or 3-6) woolly sepals, no petals, and numerous

stamens with shaggy filaments. The stamens are replaced by staminodes in the female flowers, in the centre of which are 5 (or 3-6) spreading styles. The fruit is a many-seeded orange-yellow berry about the size of a pea.

There is a variety called *crispa* rarely seen, and now perhaps not in cultivation, remarkable for its curiously cut and crisped leaves.

Culture and Propagation.—This tree is fairly hardy in the neighbourhood of London, in warm sheltered situations, and thrives in ordinary good garden soil, which must as a matter of course be well-drained. It may be increased by inserting cuttings of the more or less ripened shoots in sandy soil during the summer and autumn months, and placing them in gentle heat under glass. Seeds, if obtainable, may be sown as soon as ripe or in spring in light rich soil, and placed in bottom heat.

XVI. PITTOSPOREÆ

A small order of usually smooth shrubs or small trees with alternate, entire, toothed, or very rarely incised leaves, without stipules. Flowers hermaphrodite, regular, or slightly oblique. Sepals 5, usually distinct. Petals 5, hypogynous, longer than the sepals. Stamens 5, hypogynous, free, alternating with the petals. Fruit a capsule or berry.

PITTOSPORUM.—A genus of usually smooth and evergreen shrubs or small trees with entire or sinuate-toothed leaves, often more or less whorled near the ends of the branches. Flowers borne in various ways in clusters at the ends or sides of the branches. Sepals distinct or united at the base. Petals more or less cohering in a tube, or rarely spreading. Ovary sessile or shortly stalked. Fruit a roundish, ovoid, or pear-shaped capsule.

Culture and Propagation.—Although about 50 species have been described in this genus, those mentioned below are the only ones suitable for cultivation in the open air in the milder parts of the British Islands. They are fairly hardy in ordinary winters in the neighbourhood of London, and on the west and south coast even *P. Tobira* has been uninjured by 20° of frost.

Pittosporums will thrive in any good and well-drained garden soil, but they prefer a rich fibrous loam with a little sand and leaf mould added. They may be increased during the summer months

by means of cuttings of the half-ripened shoots inserted in light sandy soil under a handlight or bell glass, and placed in gentle bottom heat. The plants thus raised may be grown on under glass until they are large enough and thoroughly hardened off to stand being planted out of doors, an operation best performed during mild weather in spring.

P. crassifolium (*P. Ralphi*).—An ornamental bush 4-10 ft. high, native of New Zealand, where it is known as the 'Parchment Bark.' The branches are clothed with rather narrowly oblong obovate light green leaves, quite smooth and shining above, but rather woolly beneath. The deep brownish-purple flowers are produced in abundance in early summer in stalked and nodding umbels.

Culture &c. as above.

P. Tobira (*P. chinense*).—A pretty Japanese shrub 10-12 ft. high, with bluntly obovate smooth leathery leaves, and clusters of white sweetly scented

flowers produced during the summer months.

Culture &c. as above.

P. undulatum.—An ornamental Australian shrub 6–10 ft. high with oval lance-shaped, wavy, deep green, and rather leathery leaves, tapering at both ends. The small white flowers appear in early summer in somewhat downy clusters.

Culture &c. as above.

BURSARIA.—A small genus of stiffish and rather spiny shrubs, with small entire leaves often in clusters. Flowers small, whitish, in pyramidal panicles at the ends of the branches. Sepals minute, distinct. Petals narrow, spreading almost from the base.

B. spinosa (*Itea spinosa*).—An ornamental evergreen spiny shrub 6–10 ft. high, native of Australia, with small and entire oblong wedge-shaped leaves and trusses of small white flowers produced during the summer and autumn months in favourable situations.

Culture and Propagation.—Although fairly hardy in warm and sheltered situations in the vicinity of London, this plant is much more luxuriant in the milder south and western parts of the kingdom. It thrives in good and well-drained garden soil, but has a preference for rich loam and peat or leaf soil in about equal proportions. Cuttings of the young or half-ripened shoots may be rooted in gentle heat under glass in the same way as *Pittosporums* above, p. 236.

XVII. POLYGALÆ—Milkwort Order

Erect or climbing herbs or shrubs with alternate, rarely opposite, simple entire leaves, always destitute of stipules. Flowers hermaphrodite, irregular, usually in spikes or racemes, often small and inconspicuous but showy in many species of *Polygala*. Two to three small bracts are at the base of the pedicels. Sepals 5, free, the 2 inner larger and petal-like and known as the 'wings.' Petals 3 or 5, hypogynous, of which one known as the 'keel' is larger than the others. Stamens 8, rarely 5 or 4, hypogynous, with filaments united in a split sheath, which is usually adnate to the petals. Ovary free, 2-celled (rarely 3–5-celled). Fruit usually opening through the valves; sometimes indehiscent, membranous, fleshy, leathery, drupe-like or winged.

There are about 400 species in this order, distributed throughout temperate and warm regions.

POLYGALA (MILKSEED; MILKWORT).—An extensive genus containing about 200 species, of which only those mentioned below are worth growing out of doors, although there are many pretty species suitable for greenhouse cultivation. There are 3 species native of Britain.

The *Polygalas* are chiefly shrubs or undershrubs, or herbs, with alternate, or rarely opposite, or verticillate leaves. Flowers pea-like in appearance, in terminal or lateral racemes, rarely axillary, sometimes in contracted heads, rarely paniculate. Flowers sometimes showy, sometimes minute, variously coloured. Sepals 5, unequal, the 2 inner ones large, petal-like, forming wings. Petals 3, coherent. Stamens 8, with filaments united.

Culture and Propagation.—The species described below are chiefly useful for rockeries, and thrive in fibrous peat and sandy loam mixed, in a somewhat shaded place. They are increased from seeds, or by cuttings struck under glass. The seeds may be sown as soon as ripe in cold frames, protecting the seedlings afterwards under glass until the following spring. Or the seeds may be sown in spring in the same way, and the seedlings grown on singly in pots until the following spring before transferring them to the outdoor garden.

P. Chamæbuxus (*Bastard Box*).—A pretty creeping shrub 6 in. high, found wild in the mountain woods of Austria and Switzerland. Leaves oblong lance-shaped, with a point at the apex. Flowers in early summer, creamy or yellow,

tipped with purple, fragrant, in axillary few-flowered racemes. The variety *purpurea* is a much prettier plant, with bright magenta-purple flowers, clear yellow in the centre.

Culture &c. as above.

P. paucifolia.—A North American herbaceous perennial 3 in. high, with simple erect stems, naked below, and ovate leaves. Flowers from May to

August of a fine rosy-purple colour, sometimes white, large, in threes; keel crested.

Culture &c. as above.

P. Senega (*Seneca Snake Root*).—Also native of N. America, 6-12 in. high, with lance-shaped or oblong, rough-margined leaves. Flowers in May and June, almost sessile; wings roundish obovate, concave; crest short.

Culture &c. as above.

XVIII. FRANKENIACEÆ—Sea Heath Order

An order with only one genus (*Frankenia*) consisting of perennial herbs or much-branched undershrubs with jointed nodes. The leaves are opposite, small, without stipules, and the usually pink flowers are regular and hermaphrodite, being sessile in the division of the branches, and terminal, embosomed in the leaves. Sepals 4-6, united in a furrowed tube. Petals alternate with the sepals, hypogynous, clawed, often with appendages at the base of the limb. Stamens, 6, sometimes 4, 5, or numerous, hypogynous, free, or slightly connate at the base. Ovary 1-celled, many-seeded. Fruit 2-, 3-, or 4-valved, enclosed by the calyx.

This order contains about 30 species chiefly natives of Northern Africa and Southern Europe, although a few are indigenous to South Africa, New Holland, and temperate Asia.

FRANKENIA lævis (*Sea Heath*).—This is a small creeping evergreen with pubescent stems and wiry branches having oblong linear leaves with reflexed margins, and small rose-coloured flowers which appear in July and August. It is found wild on our southern sea coasts and the Channel Islands, and may be used in the rock garden.

Culture and Propagation.—This species will thrive in ordinary garden soil, and may be used in sunny and rather dry positions. It is most readily increased by dividing the rootstocks in early autumn or in spring. Seeds may also be sown in cold frames as soon as ripe, or in the open border in April and May, but they are more easily attended to if sown in boxes or pans in a cold frame or greenhouse.

XIX. CARYOPHYLLÆ—Carnation, Clove, and Pink Order

A large order containing from 800 to 1,200 species, natives chiefly of the cold and temperate parts of the world. Annual or perennial herbs, rarely shrubby, branches usually thickened, and sometimes jointed, at the nodes. Leaves always opposite and entire, often connate at the base, often 1-3-nerved; stipules none, or if any small and scarious. Flowers hermaphrodite, rarely unisexual by abortion. Sepals 4-5, persistent, distinct or cohering in a tube. Petals 4-5, hypogynous or slightly perigynous, entire, or frequently split into 2 parts, sometimes minute, scale-like, or absent. Stamens (8-10) usually twice as many as the petals, in two circles, of which the inner is often wanting; filaments awl-shaped. Fruit a 2-5-valved capsule with numerous seeds. Placenta free, central.

DIANTHUS.—This is the genus to which Carnations, Pinks, and Sweet Williams belong botanically. At one time

as many as 200 species were described under it, but this number has been reduced to about 70 by Bentham and Hooker.

They are chiefly perennial, occasionally sub-shrubby herbs, with narrow grassy-like glaucous leaves. Flowers terminal, solitary, paniced, or clustered, often rose or purple, rarely white or yellow. Calyx tubular, 5-toothed, with imbricating bracts at the base. Petals 5, with long claws, the blade entire, many-toothed or cut, or notched in two, hairy or smooth above, or with claws produced into scales. Stamens 10, capsule cylindrical-oblong, rarely ovoid, opening by 4 teeth or valves.

The following are some of the best kinds in cultivation out of doors. Their culture and propagation are the same as those of the Carnation (*Dianthus Caryophyllus*), the Pink (*D. plumarius*) and the Sweet William (*D. barbatus*), under each of which instructions will be found.

D. alpestris.—A native of the Alpine pastures of Europe, 6-9 in. high, with linear-lanceolate leaves. Flowers in July, red, usually in pairs; petals emarginate.

Culture &c. the same as for *D. cæsius* below, as well as notes for each species.

D. alpinus.—Native of the Austrian Alps, 3-4 in. high. Leaves oblong-linear, blunt, green. Flowers in summer, large, deep rose spotted with crimson, solitary, and very freely produced; petals crenated.

Culture &c. the same as for *D. cæsius* below.

D. arenarius.—Native of N. Europe. Flowers in summer, white, with a livid spot and purple hairs at the base of the deeply divided petals.

Culture &c. the same as for *D. cæsius* below.

D. atrorubens.—A species 1 ft. high, native of S. and E. Europe, with 3-nerved linear leaves. Flowers in summer, dark-red, small, sessile, in clusters, with an awned involucre.

Culture &c. the same as for *D. cæsius* below.

D. barbatus (*Sweet William*).—The type of the well-known Sweet William is a native of S. and E. Europe, 1-2 ft. high, with lance-shaped nerved leaves. Flowers in summer, variously coloured, from dark purple to white, in dense heads; petals bearded.

There are almost innumerable varieties or forms of the Sweet William, and of late years they have been much improved from the florist's point of view. The individual flowers are larger, more circular

in shape, thicker petalled, and have the colours more clearly defined. In what is called the 'Auricula-eyed' section, the flowers have a clear white centre surrounded by red, purple, or some other deep, rich colour. There is also a section in which the teeth of the petals are almost if not quite obliterated, being called 'smooth-edged.' 'Self-coloured' flowers exist also, being either pure white, pink or crimson. But there are a vast number of pretty flowers variously edged, spotted, mottled &c., which remain. There is a double dwarf variety called *magnificus*, with deep velvety crimson flowers, but the other double kinds are not particularly desirable. The forms known as *fulgens*, *nigricans*, *candidus*, *oculatus*, *marginatus*, and *nanus* are all handsome, and their peculiar features are expressed in the names.

Culture and Propagation.—Sweet Williams are easily raised from seeds sown in the open border or in cold frames as soon as ripe, or in spring about March and April. The seedlings may be pricked out when about 2 in. high into light rich soil, and may be transplanted either in early autumn or spring in mild showery weather, according to the period at which the seeds were sown.

Where plants are once established in a garden any number of self-sown seeds will come up every year. By thinning out or transplanting into good soil six inches apart about the end of September, the plants will become well-established for the winter and will flower freely the following summer. Special varieties may be increased by cuttings taken in early summer, and inserted in rich sandy soil in a shaded place. Transplant in September to the flowering positions. The plants may also be divided in September, but Sweet Williams being better treated as biennials, neither this mode of propagation nor cuttings is much practised, except when it is desired to keep some particularly fine variety quite true.

D. bicolor.—A native of S. Russia, 1-2 ft. high, with awl-shaped leaves, the lower ones woolly. Flowers in summer, white above, lead-coloured beneath; petals dilated.

Culture &c. as for the next species *D. cæsius*.

D. cæsius (*Cheddar Pink*).—A very glaucous species 3-6 in. high, native of

Britain (the limestone rocks of Cheddar). Leaves of the barren shoots linear, blunt, the upper ones of the flowering stems acute. Flowers in June and July, 1 in. across, fragrant, delicate rose; petals obovate, crenate, downy.

Culture and Propagation.—The Cheddar Pink is a beautiful plant for making a carpet at the edge of the flower border, or may be used in masses in the rockery. It likes a rich sandy soil and a warm sheltered position to appear at its best. It ripens seeds freely, and these may be sown in the same way as described above for Sweet Williams (*D. barbatus*). It is, however, much easier to increase the plants simply by dividing them during mild showery weather, either in early autumn or in spring. Once established the plants need not be disturbed for three or four years unless they exhibit signs of weakness. Besides seeds and division most of the perennial species of *Dianthus* may also be increased by cuttings and layers in the same way as stated for Carnations, p. 242.

D. callizonus.—A beautiful alpine Pink, native of Transylvania, with a dense tufted habit and lance-shaped pointed blue-green leaves. It flowers profusely during the summer months; the rich rosy-purple blossoms are 1½–2 in. across, with a distinct deep purple zone in the centre, and scarcely overtop the bed of blue-green foliage, but rather nestle amongst it.

Culture and Propagation.—This plant does not apparently seed freely in the British Islands, although it is perfectly hardy. It may, however, be easily increased by division in autumn or spring, like *D. cæsius*, and also by means of cuttings placed in sandy soil. It is an excellent rock plant.

D. Caryophyllus (*Carnation; Clove; Pink*).—The Wild *Carnation* is naturalised here and there on old castle walls in England, and is also distributed all over Central and E. Europe. It is a stout glaucous smooth perennial, much branched and leafy below, 18–24 in. high. Leaves 4–6 in. long, linear awl-shaped, grooved above. Flowers in summer, 1½ in. across, fragrant, nearly every colour except blue, but rosy in the type; petals broadly obovate, toothed and crenate.

CARNATIONS

The *Carnation*, like the *Rose*, has for several centuries been a favourite garden

plant, and careful selection and cultivation by generations of gardeners through these long years have produced flowers so beautiful in shape, and so diversified in colour, that one can hardly imagine them to be descended from such a simple plant as *D. Caryophyllus* described above.

Carnations are divided into three main groups by florists, viz.:—*Bizarres* (subdivided into crimson, pink, and purple, and scarlet-flowered); *Flakes* (subdivided into purple, rose, and scarlet); and *Selfs*, which as the name indicates have flowers of a uniform colour of any shade throughout.

The *Bizarres* are variously coloured or spotted or striped, with two or three distinct colours on a clear ground. The *Flakes* have a pure ground flaked with one colour only the entire length of the petals.

PICOTÉES

Besides the *Carnations* proper, there is also a very important and beautiful class known as *Picotées*. These are easily distinguished by having a ground colour, the petals being edged with a distinct and striking colour. This edging may be either 'heavy' or 'light,' and serves to separate *Picotées* into two sections, in each of which the edges may be either purple, red, or rose; in addition to which are the 'Yellow ground' *Picotées*, a vigorous class in which the flowers are various shades of yellow, buff and apricot, sometimes marked on the edges, or with lines radiating from centre to edge.

What are known as 'Tree or Perpetual' *Carnations* are usually grown under glass for flowering in winter in pots. They do not therefore come within the scope of this work.

In the olden days, there was also a section known as 'Painted Ladies,' in which the under side of the petals was white, and the upper side red or purple, as if painted on the white. This class has practically disappeared from cultivation altogether, but the National *Carnation* and *Picotée* Society may endeavour to revive it some day.

The characteristics of a good *Carnation* or *Picotée* flower may be said to consist of a circular outline, with smooth and rounded edges, regularity in size and shape of the petals, and a calyx which does not split. Where a tendency to burst the tubular calyx exists, a thin

piece of raffia or worsted may be carefully and not too tightly tied round it, so that the flower can open freely. It may be mentioned that there are many Carnations—like the Tree section and others—which have fringed or toothed petals, many of them very beautiful.

Culture and Propagation.—This is precisely the same as detailed for Carnations below.

Marguerite Carnations.—A new and distinct race remarkable for the rapidity with which they produce their flowers after sowing the seed. About 70 or 80 per cent. of the flowers (which are beautifully fringed and of many charming shades) come double. Seeds, if sown in gentle heat in early spring, will produce flowers out of doors by July or August. Or better still the seeds may be sown in cold frames about August and September, and after the seedlings have been pricked out once, they may be grown in the cold frames until the following April and May, when they may be planted out in mild weather. The plants should have as much light and air as possible during the winter months on all favourable occasions. They are very useful for room decoration, in a cut state.

'Jacks.'—This peculiar name is applied to the large and vigorous growing Carnations which are grown in hundreds of thousands annually, chiefly to supply the great trade done in them by costermongers. There is no doubt whatever that nearly 100 per cent. of the amateurs who buy these plants do so in the belief that they are obtaining some very choice double-flowered kinds, such as they see in florists' windows or in other amateurs' gardens. These 'Jacks' are mostly single-flowered Carnations, raised from seeds in spring, and afterwards planted out and grown on until the following spring. They are then taken up for sale, and as they are apparently remarkably cheap, they find a ready sale among cottagers and the uninitiated. As a rule, however, the purchasers are disappointed when the plants bloom, owing to the prevalence of single flowers among them.

CULTIVATION

Although there are naturally many allures in Carnation growing, the plants are not really difficult to grow. The failures usually result from too much coddling and shifting about, and never

allowing the plants to have a fair chance. Of course where plants have been accustomed to the protection of frames during the winter, and grown in pots, they are not nearly so hardy and vigorous as those grown without any protection, and what is worse, they are not so well able to ward off or withstand the attacks of insect and fungoid pests. Of late years great efforts have been made to secure a really hardy race of Carnations, for the flower garden, and there are now a large number of varieties which will grow without any protection in winter in almost any part of the British Isles. Where, however, any one does not wish to run risks with extra fine varieties whose actual hardiness has not been tested by experience, it may be well to give some slight shelter; but the hardiness or otherwise should be tested as soon as a plant can be easily spared for the experiment.

Soil.—The best soil for Carnations is a rich loamy one, with plenty of leaf soil, and a portion of well-rotted stable manure, and enough coarse sand to keep it open. Light hot soils are quite unsuitable for Carnations, and should be well enriched with leaf soil, farmyard and other vegetable manure with a view to making it cooler and more retentive of moisture. Soil should always be well dug some time before planting except in cases where the plants succeed a totally distinct crop.

Manure.—This should never be applied in a fresh state, and certainly not to the roots when planting. It is best applied in a rotten state and as a mulch on top of the soil in spring. Soot is an excellent fertiliser; it tends to give the foliage a fine 'bloom,' and is also more or less obnoxious to slugs, snails &c. Various artificial manures, such as nitrate of soda and sulphate of ammonia, are also beneficial, but their use is attended with great risk—the inclination for a beginner being to give an overdose which would probably kill the plants. If given at all, these are best in a liquid form, say a teaspoonful to a gallon or two of water.

Planting and Layering.—Late planting is responsible for many deaths during the winter. In Scotland planting should be finished by the first or second week of September, and practically about the same period in England and Ireland. In order to be able to do this the layers should also have been made at a period

correspondingly early—say the first and second weeks of July—thus giving them about 3 full months to become established plants.

The benefits of layering and planting early are obvious. The plants are well leaved and their roots well established in the soil before winter sets in. They are thus in a position to resist the frost; they bloom earlier in spring, and the chances are that the flowers are not only finer, but in much greater abundance than from later planted specimens.

An important point to remember in connection with planting is not to insert the plants too deeply in the soil. Spread out the roots carefully and cover them firmly, but do not bury the stems beyond half an inch or so. If in rows, the plants should be about 9 in. apart, with at least a foot between the rows, to allow of hoeing &c. in spring.

Staking.—Each plant should be provided with a stake about 3 ft. high at time of planting, and the stems should be neatly tied, so that they do not chafe when blown about by the wind. Attention to staking is essential, otherwise the branches and blooms will straggle about in the dirt, and be more or less worthless.

Position.—Perhaps the most natural and ornamental way to dispose of Carnations is to plant them in groups, large or small according to the space available. They are thus seen to better advantage when in bloom, and it is easier to notice their general peculiarities, than if planted here and there in isolated specimens. Where possible the plants should be so placed as to be sheltered from the north and east, and fully exposed to the west, and more or less partially shaded from the summer sun when facing south. About 9 in. to 12 in. apart will not be too crowded for the plants.

PROPAGATION

Carnations are increased by seeds, layers, and cuttings—the latter being known as ‘pipings.’

Seeds are usually sown in April and May in pots or shallow pans. The soil should be rather finely sifted, and composed of loam, leaf soil and silver sand. It is best to carefully place the seeds about $\frac{1}{2}$ in. apart, slightly cover them with soil, and place in a cold frame after watering with a fine-rosed can.

When about 6 leaves have developed, the seedlings may be pricked out round the edges of a pot or in a shallow box, about 2 in. apart in a similar compost. As soon as the plants are 3–4 in. high, they may be pricked out into beds or borders, about 4 in. apart, and by the first week of September they should be fine sturdy plants fit for removing to their flowering positions. It should be borne in mind that Carnations from seed are liable to vary a good deal, and that many of the flowers will be single, and others poor in quality. Still there is a possibility of a really fine variety appearing among them, in which case it should be carefully labelled and kept for stock.

Layering is perhaps the most common method of increasing Carnations and Picotees. As stated above, layers should be made by the first and second week of July with a view to getting strong established plants before winter. A fresh compost like that in which the seeds are sown should be placed round the base of each plant, about 2 in. deep. The leaves of the lower portion of each shoot to be layered should be stripped off, leaving about 3 or 4 leafy joints above. A slit should then be made lengthwise with a sharp knife, just below a joint which is neither too woody nor too tender or sappy, taking care not to sever the shoot from the plant, but about halfway through, so as to form a tongue. The shoot thus cut should then be carefully pegged down with a piece of bracken stem, or a hair-pin, in such a way that the cut is left open and the tongue is firmly fixed in the soil. A little more compost should then be placed over the pegged portion of the shoot. When every branch has been treated in the same way, the soil should then be well watered, using a fine-rosed can, and in a month or so the layers will be rooted. By the first or second week of September they may be severed and transplanted. The sketch at p. 59 will show at a glance the way in which the shoot of a Carnation or Picotee may be layered.

Pipings or Cuttings.—Carnations increased by this method are never quite so good as those from layers, but it is employed in the case of rare or special kinds to obtain stock more quickly, or when the shoots are too short and numerous for layering. The pipings should be taken with a ‘heel’ or cut off at

a joint which is fairly well ripened, but not woody. They should then be firmly inserted in a fine sandy compost, well watered, and placed in a close and shaded frame, for 3 or 4 weeks, after which they may receive plenty of air, and will be ready for transplanting at the season recommended.

In the case of layers and cuttings, the tops of the outer leaves are often snipped off with the knife. It is then easy to see when new leaves are forming, as of course their tips will not be mutilated. The thin lines across the leaves in the sketch show how the tips are cut off.

Thinning the buds.—With the exception of those who make a business of exhibiting Carnations for prizes, the practice of removing some of the flower buds is seldom or never practised. By reducing the number of flowers to each stem, and even by cutting out a whole flower stem now and again, the flowers left will certainly be much finer and fuller when developed.

DISEASES

When Carnations are continuously grown on the same soil, or on cold heavy land, or too closely together, they become more or less subject to various diseases. And some varieties which thrive in the south are miserable failures in the north, and *vice versa*.

The Carnation Rust (*Uromyces Caryophyllinus*) appears on the stem or leaf as a pale raised pustule, over which the epidermis soon breaks, hanging round the edges in a ragged state, revealing the brown powdery reproductive spores of the fungus. These may be blown or washed from plant to plant, spreading the disease rapidly, when in a proper state for germinating. It may be checked by finely spraying with sulphide of potassium, dissolving one ounce to 10 gallons of water.

Leaf spot is a troublesome disease often caused by a damp atmosphere or over-crowding. It appears on the leaves and stems as a more or less circular purplish spot with a whitish centre, the latter being often dotted with black by the fruiting portions of the fungus. The fungus enters the tissues of the plant rather deeply, and the spores which are produced in great abundance are rapidly distributed by wind and water. It does not, however, attack all varieties with

equal virulence. The plants may be dusted with a mixture of soot and sulphur, or sprayed with sulphide of potassium as recommended for rust. *Gout* is a disease which attacks the stems close to the ground, and is supposed to be caused by 'eel-worms' which enter the plant to lay their eggs, out of which come other worms to feed upon the plant and kill it. Plants grown in too rich a soil, and making sappy growth, are more subject to attacks than others.

The *maggot* is a pest which often attacks Carnations. The eggs are laid in the tissues of the leaf, and the young insects eat their way down the main stem to the centre and kill the plant. The plants should be carefully watched, and the eggs destroyed between finger and thumb wherever discovered.

Spittle-fly is easily seen. It appears when the plants are in bud, and should be squeezed to death between the finger and thumb.

D. chinensis (D. sinensis).—*Chinese or Indian Pink.*—A Chinese biennial 6-12 in. high, with pale green lance-shaped leaves. Flowers in summer, usually reddish, but very variable in colour, either single or double, with toothed petals. Among the many forms of *D. chinensis*, the following may be noted as distinct: —*albus*, flowers double, white; *carneus*, flowers double, flesh-coloured; *fulgens*, flowers double, brilliant scarlet crimson; *nanus albus*, *n. atro-sanguineus*, and *n. flore pleno*, all dwarf forms; *laciniatus* is a fine Japanese form with very blue-green foliage and flowers about 2 in. across, remarkable for having the petals deeply incised or jagged almost half the length of the blade. The variety *Gardneri* is a native of China, it has very large flowers with finely cut petals. The variety *Atkinsoni* is a beautiful old-fashioned hybrid Pink, with deep blood-red flowers. It does not ripen seed, and is rather difficult to increase by division or cuttings. *D. Heddeveggi* is a beautiful annual or biennial with variously coloured flowers—single and double. Very useful for borders in summer. The forms of *Heddeveggi* known as *atropurpureus* and *diadematus flore pleno* are very distinct and worth a place in the flower border.

Culture and Propagation.—*D. chinensis* and its varieties may be treated as tender annuals or biennials. As annuals the seeds may be sown about March in

gentle heat in light and rich well-drained soil. When about 2 in. high the young plants may be pricked out into other boxes about 2 in. apart, and grown on under glass until the end of May or beginning of June. In the meantime they must have plenty of light and air, and be gradually hardened off so as to be ready for the outdoor garden at the time stated. Besides sowing under glass, the seeds may also be sown in the open border in April and May in patches, where the plants are to bloom eventually. In this case the seedlings are to be thinned out about 6 to 8 in. apart, as if transplanted at that late period the plants will hardly come into bloom the same season, except in the south and west.

D. cinnabarinus.—A free-growing species, native of Greece, with tufts of linear leaves. The flowers appear in summer, and are a beautiful orange or cinnabar-red.

Culture &c. as for *D. deltoides*.

D. cruentus.—Native of E. Europe. Leaves linear lance-shaped, very acute, lower ones tufted. Flowers in summer, small, numerous, blood-red, scarlet; petals toothed, bearded near base with scattered reddish-violet hairs.

Culture &c. as for *D. deltoides*.

D. deltoides (Maiden Pink).—A much branched British perennial 6–9 in. high. Leaves narrow lance-shaped, downy, the lower ones blunt. Flowers from June to September, $\frac{3}{4}$ in. across, rarely 2 together, rose-coloured, with a dark circle spotted with white, or white in the variety *albus*. Calyx smooth, strongly ribbed.

Culture and Propagation.—The Maiden Pink is excellent for carpeting borders and rockeries with its dense masses of leaves and flowers. It likes a rich sandy soil and a warm sheltered position to appear at its best. It ripens seeds freely, and these may be sown in the same way as described above for Sweet Williams (*D. barbatus*). It is, however, much easier to increase the plants simply by dividing them during mild showery weather, either in early autumn or in spring. Once established, the plants need not be disturbed for three or four years unless they exhibit signs of weakness. Besides seeds and division most of the perennial species of Dianthus may also be increased by cuttings and

layers in the same way as stated for Carnations.

D. dentosus (Amoor Pink).—A native of S. Russia, 6 in. high. Leaves rather broadly linear, sometimes slightly wavy, glaucous, tinged with a reddish hue, especially in autumn. Flowers in summer, violet-lilac, more than 1 in. across, with a regular dark spot formed of purple streaks at the base of each petal, producing a dark eye in the centre. Petals toothed at the edge, bearded at the base.

Culture &c. as for *D. deltoides*. The Amoor Pink seems to have crossed readily with some of the other species, as there are now several varieties of it in cultivation, some with double or semi-double flowers, all larger than those of the type. These double-flowered forms are mostly sterile and do not produce seed. They must, therefore, be increased by division.

D. fimbriatus.—Native of Spain, 1 ft. high, with awl-shaped, roughish leaves. Flowers in summer, rosy, solitary. Petals oblong, multifidly toothed, beardless, somewhat like those of *D. superbus*.

Culture &c. as for *D. superbus* below.

D. Fischeri.—A somewhat rare Russian species 7–10 in. high, with stiff lance-shaped serrulated leaves. Flowers in summer, light rose, with petals much cut or feathered at the edge, almost beardless at the base.

Culture &c. as above for *D. deltoides*.

D. fragrans.—Native of the Caucasus, 6–9 in. high, with awl-shaped, rough-edged leaves. Flowers from July to September, white, fragrant, suffused with purple. Petals somewhat cut, beardless.

Culture &c. as above for *D. deltoides*.

D. Freyni.—A beautiful perennial of garden origin, forming dense masses or cushions of foliage, and producing in early summer, and often again in autumn, bright rosy-carmine flowers, about $\frac{3}{4}$ in. across, sitting close to the grassy foliage, the entire plant being not more than 2 in. high altogether.

Culture &c. as above. This pretty little plant is apt to rot off at the ground if placed too low down. It does not spread by means of suckers like some other species, and is best propped up between two or three pieces of limestone rock, so that water will pass readily away from it. As slugs are rather partial to it a watch must be kept for them.

D. fruticosus.—A shrubby-stemmed species 1-2 ft. high, native of the Grecian Archipelago. Leaves bluntly obovate lance-shaped. Flowers in summer, dark in the centre, rose at the edge, white and hairy at the base.

Culture &c. as above for *D. deltooides*.

D. gallicus.—Native of France, Spain and Portugal, about 6 in. high, with linear, somewhat ciliated leaves. Flowers in summer, white, dull purple at the base. Petals much cut and toothed.

Culture &c. as above for *D. deltooides*.

D. giganteus.—A native of E. Europe 2-4 ft. high, with long linear leaves connate at the base. Flowers in summer, purple, numerous, in hemispherical heads, supported by leafy bracts.

Culture &c. as above for *D. deltooides*.

D. glacialis (*Glacier Pink*).—A native of Central and S.W. Europe, 2-4 in. high, with short erect tufted stems, and linear acute serrulated green leaves. Flowers in summer, small, purple, scentless; petals toothed.

Culture &c. as above for *D. barbatus*. This species is best raised from seeds, as it often dies out when pulled to pieces. It does best in crevices in the rockery in peat soil, mixed with nodules of rock for support.

D. Holtzeri.—A fine species from Turkestan. Leaves linear lance-shaped. Flowers pink, about 1½ in. across; petals more or less fringed.

Culture and Propagation.—This comes very near *D. superbus*, and is probably only a variety of it. It requires the same treatment and may be increased like *D. superbus*. The following forms have been noted: *dentatus*, with sharply toothed petals; *ebarbatus*, with paler flowers than the type, and scarcely any hairs in the throat; *imbriatus*, with fringed petals, and *flaccidus*, with weak decumbent stems and rosy-purple flowers.

D. Knappi.—A very distinct species about 1 ft. high, native of Eastern Europe. It is closely related to *D. liburnicus*, and has narrow lance-shaped leaves. The flowers appear in July and August and resemble those of a Sweet William. They are, however, remarkable for being of a clear primrose-yellow, and therefore singular and interesting among single-flowered Dianthus.

Culture &c. as above for *D. deltooides*.

D. latifolius.—The native country of this species is unknown. It is about 1½ ft. high, with oblong lance-shaped leaves, and somewhat resembles the Sweet William in habit. Flowers in summer, pink, in clusters.

Culture &c. as for *D. chinensis* and *D. barbatus* above. The plant described here is possibly a variety of the Indian Pink or the Sweet William.

D. liburnicus (*D. Balbisi*).—A glaucous plant 1-2 ft. high, with angular stems, and lance-shaped linear leaves. Flowers in summer, red, almost sessile, in capitate clusters. Native of S. Europe.

Culture &c. as above for *D. deltooides*.

D. monspessulanus (*Montpelier Pink*). A native of S. and E. Europe, 6-12 in. high. Leaves linear, serrulate. Flowers in summer, red or white, solitary; petals digitately cut, smooth in the throat.

Culture &c. as above for *D. cæsius*.

D. neglectus.—A lovely alpine Pink, native of the Pyrenees, the high Alps of Dauphny &c., and closely related to the Glacier Pink, *D. glacialis*. In its native state it only reaches a height of 1-3 in., but in cultivation often as much as 6-8 in. It has a strong sturdy habit, forming tufts of rather blue-green grassy foliage. The beautiful and brilliant deep rosy flowers, quite an inch across, appear in summer and have the petals attractively mitred or serrated at the edge, the backs of the petals being of a nankeen colour.

Culture and Propagation.—This species, if grown in sandy well-drained soil, even if rather poor, will stand almost any winter. It flowers very freely and is easily increased by division of the tufts or by means of seeds, which ripen in favourable seasons, and should be sown in cold frames at once, or even in the rockery under a sheet of glass.

D. pallidiflorus.—A Russian species 6 in. high, forming dense branching tufts. Leaves linear, pointed, flat, sessile. Flowers late in summer, purple-rose, numerous, solitary.

Culture &c. as above for *D. deltooides*.

D. petræus (*Rock Pink*).—Native of E. Europe, 1-6 in. high, with smooth awl-shaped, entire leaves. Flowers in summer, fine rose, numerous, usually solitary; petals beardless, cut at the

edges. There is a pretty form with double flowers called *flore pleno*.

Culture &c. as above for *D. deltooides*.

D. plumarius (*Garden Pink*; *Pheasant's Eye*).—This is supposed to be the origin of all the Garden Pinks. It is a glaucous plant 9–12 in. high, native of Eastern Europe, and naturalised on old walls in various parts of England. Leaves linear, rough-edged. Flowers in summer, white, purple, either single or double, spotted or variegated; petals bearded, jagged. The variety called *serotinus* blooms somewhat later than the type, and *flore pleno* has double creamy-white flowers.

Garden Pinks have always been great favourites owing to the great freedom in which they produce their beautiful sweet-scented flowers, their dwarf, tufted habit, and their great hardiness, surpassing in this respect the Carnation.

Culture and Propagation.—Pinks may be propagated by exactly the same methods as recommended for Carnations, viz. by seeds, layers, and cuttings (pipings). The latter method is usually adopted, as many of the varieties are too short, close and tufted to readily admit of layers being made. The mode of procedure is the same as for Carnations (see p. 242).

In June or July, when the stems are fairly well ripened, cuttings, or 'pipings' will readily root in light sandy soil under handlights if placed in a cool and shaded part of the garden. When well rooted, the plants may be transferred to their flowering positions, but all planting should be finished by the end of September at least. If plants are moved much after October it is safer to winter them in cold frames, as they will not have had sufficient time to enable them to develop new roots and become established before the approach of winter.

Soil similar to that for Carnations is also best for Pinks. The latter, however, do not like too much moisture at the roots, and where possible the Pink beds or borders should be somewhat raised above the ordinary level. Top dressings of rotted manure, spent mushroom beds &c. are very beneficial in spring and summer, and water must not be lacking in the hot weather. Where particularly fine flowers are required, some of the blooms may be pinched off, leaving the most likely ones only to develop.

Pinks are usually divided into two

classes, viz. *Show* or *Laced Pinks*, and *Border Pinks*. The latter are most suitable for outdoor cultivation, but are also forced a good deal in greenhouses for early bloom. The 'Show' or 'Laced' varieties are grown under glass especially for exhibition purposes. The following is a selection of the best Pinks for outdoor cultivation:—

WHITE-FLOWERED VARIETIES

Alba maxima, large border variety, fine for bouquets; *Albino*, an improvement upon *Snowflake*, almost like a Carnation, fine full flower; *Alice Lee*, Carnation, *Fairy King*, *Her Majesty*, pure white of exceptional size: in the opinion of some, the very best; *Mrs. Sinkins*, fine border variety, fine for bouquets; *Mrs. Welsh* and *Snowflake*, the latter a lovely variety with branching stems; it rarely bursts.

VARIOUS

Anne Boleyn, rose-purple; *Ascot*, pink; *Bertha*, white, rosy centre; *Boiard*, very large, white, bright red lacing; *Conqueror*, dark red, laced; *Empress of India*, white, laced purple; *Ernest*, red, broad lacing, large; *Ernest Ladhams*, light pink with deeper centre, flowers as large as a *Malmaison*; a fine novelty, wonderfully free; *John Ball*, dark plum-purple; *Lena*, rosy-purple; *Lorina*, pink; *Lowlander*, red; *Masterpiece*, purple-maroon; *Minnie*, bright red; *Modesty*, white, rose centre, evenly laced; *Mrs. Pettifer*, white, purple centre, heavily laced; *Professor*, red; *Sarah*, fine white, darkly velvety red centre, perfect; *Vigilant*, red.

D. ramosissimus (*Bush Pink*).—A free-flowering species, 6 in. high, native of Tartary, with linear pointed leaves. Flowers in late summer, purple-rose, on wiry stems.

Culture &c. as above for *D. deltooides*.

D. Seguieri.—A native of S. and E. Europe, Asia &c., about 1 ft. high. Flowers in summer, rose-purple.

Culture and Propagation.—This comes very close to *D. dentosus*, and is probably only a variety of it. It may be grown under similar conditions and increased in the same way.

D. semperflorens.—This is the name given to a comparatively new race of Garden Pinks, supposed to be the result of

a natural crossing between *D. Caryophyllus* and *D. chinensis*. They are very elegant in habit and flower profusely, the colours ranging from pure white to deep rose and carmine, the petals of some varieties being prettily striped and marked. The plants are branching in habit, and about 12-18 in. high, the stems being clothed with long lance-shaped leaves. The flowers are slightly fragrant and continue to appear until cut down by severe frosts. In a cut state they last a long time in water.

Culture and Propagation.—This race grows well in ordinary good garden soil, and the plants may be readily increased by dividing the roots in early autumn or spring. They may also be increased by means of cuttings in the same way as Carnations (see above, p. 241) at almost any season, but preferably about May and June.

D. squarrosus.—A species 6 in. high, native of S. Russia, with stiff, short, recurved, awl-shaped leaves, furrowed above. Flowers in summer, white, finely jagged at the edges.

Culture &c. as above for *D. deltoides*.

D. suavis (*Sweet Pink*).—The native country of this species is unknown. It grows about 6 in. high, and has linear, glaucous leaves. Flowers in summer, sweet-scented, pink, with bearded and deeply serrated petals.

Culture &c. as above for *D. deltoides*.

D. superbus (*Fringed Pink*).—A native of Europe and Asia, 9-18 in. high. Leaves bright green, linear lance-shaped, acute. Flowers in summer, rosy or reddish; petals divided beyond the middle, feathery, bearded at the base.

Culture and Propagation.—This charming and distinct species is not only remarkable for its beautifully fringed petals, but also for the sweet fragrance of its blossoms. Grown in masses in the rockery or flower border it makes a fine display during the summer months. It flourishes in ordinary good and well-drained garden soil, but prefers that of a rather light rich sandy and calcareous nature. It may be raised from seeds every year exactly in the same way as recommended for *D. chinensis* above.

D. virgineus.—A plant 6-12 in. high, native of S.W. Europe, with tufted, linear,

serrulate, stiffish leaves. Flowers in summer, red, with crenated petals.

Culture &c. as above for *D. deltoides*.

TUNICA.—A genus containing about 10 species of graceful slender and somewhat rigid or wiry stemmed herbs, smaller than *Dianthus*, and having narrow leaves. Flowers like those of *Dianthus* but smaller, cymose-paniculate, collected into a close or rounded head. Calyx top-shaped, or elongate-tubular, bluntly 5-toothed, 5-15-nerved, usually with a pair of imbricating bracts at the base. Petals 5, long-clawed; blade retrue or emarginately bifid, without scales. Stamens 10. Torus small, or rarely produced on a short stalk. Ovary 1-celled; styles 2. Capsule ovoid or oblong, opening at the apex by 4 teeth or valves.

T. Saxifraga.—A small perennial 2-3 in. high, found wild in dry stony parts of the Alps and Pyrenees. Leaves narrow, linear, acute, roughish. Flowers in July, rose, freely produced in loose forked panicles. Seedling forms often exhibit a good deal of variation in colour, and the flowers also come double or semi-double.

Culture and Propagation.—This is the species generally met with in gardens. It will grow in poor soil almost anywhere, and is useful for the chinks and holes in old walls, ruins &c., or for the rock garden. It may be increased by carefully dividing the numerous wiry branches with their roots in spring. Indeed, this is the only sure way to retain the characteristics of any particularly fine seminal variation. Seeds, however, are freely produced, and may be sown out of doors in warm sheltered and well-drained places or in cold frames, as soon as ripe, if extra strong plants are desired for early summer flowering. Seeds may also be sown in gentle heat about March, afterwards pricking the seedlings out and growing on until the end of May, when they may be put out of doors. Or seeds may be sown in patches where the plants are to bloom, in April and May, afterwards thinning the plants out 6-9 in. apart. By sowing seeds at intervals in this way blooming is considerably extended.

DRYPIS.—This genus contains only the following species, a native of the Mediterranean region:—

D. spinosa.—A pretty little herbaceous perennial about 6 in. high, with very rigid 4-sided stems, and stiff awl-shaped

spinescent leaves. Flowers in early summer, small, pink or white, in dense cymes, with spinescent bracteoles and calyx teeth. Calyx tubular, 5-toothed, many-nerved. Petals 5, narrowly clawed, blade bifid, without scales. Stamens 5. Torus small. Styles 3, rarely 2 or 4.

Culture and Propagation.—This plant is well suited for rockwork, and in sandy soil produces its pale pink or white flowers in great profusion. It is increased by cuttings put in sandy soil under a hand-glass, or by seed sown in spring—about March—in gentle heat. When the seedlings are large enough to handle, it is well to prick them out into their flowering positions as soon as the weather is favourable. They should be well watered until fairly established.

GYPSOPHILA.—A genus containing about 50 species of very graceful annual or perennial, usually glaucous and slightly glandulose, pubescent herbs, with flat or rarely needle-shaped leaves. Flowers usually small and numerous, panicle, calyx more or less tubular or bell-shaped, 5-toothed or 5-fid, broadly 5-nerved. Petals 5, narrow-clawed, with an entire or emarginate, scaleless blade. Torus small. Stamens 10. Styles 2, or very rarely 3. Capsule globose or ovoid, deeply 4-valved.

Culture and Propagation.—Gypsophilas thrive in ordinary garden soil, with which a little lime or brick rubbish may be mixed. They are easily increased from seeds, but the perennial kinds take quite a year to make good flowering plants. The annual kinds like *G. elegans* flower the same year—about June and July—if the seeds are sown out of doors about the beginning of April. The perennial species may also be increased by cuttings taken from the young side shoots in summer, or in autumn by dividing the rootstocks. All the Gypsophilas, however, are better increased from seed, and several sowings may be made out of doors of the annual kinds to keep up a supply of bloom.

G. arenaria.—A perennial species, native of Central Europe, in sandy, gravelly soil, about 1 ft. high, with rather fleshy, smooth, flat, linear leaves. Flowers in summer, pale red, in dense long corymbs; petals rarely notched.

Culture &c. as for *G. paniculata* below. Increased by seeds, cuttings, or division.

G. Arrosti.—A beautiful perennial 2½–3 ft. high, native of Asia Minor. Its light and graceful stems have fleshy grey-green lance-shaped leaves about 1¼ in. long, and the small white flowers appear in August in immense panicles when those of *G. paniculata* have disappeared.

Culture &c. as for *G. paniculata* below. This is a new species and well worth growing to follow on after *G. paniculata*.

G. cerastioides.—A Himalayan perennial over 3 ft. high, with erect 4-sided stems. Leaves hairy on both sides, with ciliated edges; lower leaves spoon-shaped, with long stalks, abruptly pointed. Flowers in early summer, white, red-veined; petals notched.

Culture &c. as for *G. paniculata* below. It is perfectly hardy and forms neat cushions of foliage.

G. elegans.—A charming Caucasian annual, 12–18 in. high, with slender much-branched knotted stems and opposite blue-green more or less linear lance-shaped leaves. The small, beautiful flowers, less than half an inch across, are pure white, sometimes faintly striped with violet or reddish-purple. They are borne during the summer and autumn in graceful forked panicles, which have a light and airy effect—a mass of white starry flowers over a blue-green ground.

The specific name is very appropriate, and *G. elegans* is highly valued for floral decorations. This species has recently been crossed with the perennial *G. paniculata*, and has produced an intermediate hybrid resembling *G. paniculata* in blossom, but *G. elegans* in habit.

Culture &c. as above. Raised from seeds sown two or three times annually in the open border.

G. fastigiata.—A European perennial about 1 ft. high, with rather fleshy, linear, smooth, flat leaves. Flowers in July, pale red, petals rarely notched.

Culture &c. as for *G. paniculata* below.

G. glauca.—A perennial about 18 in. high, native of the Caucasus, with downy, clammy branches, and rather fleshy, bluntly linear, lance-shaped leaves. Flowers in summer, white, in straggling panicles.

Culture &c. as for *G. paniculata* below.

G. paniculata.—A beautifully light and graceful perennial, forming a dense compact bush 2-3 ft. high, native of Europe. Stems much branched, knotty, smooth and glistening, very slender and fragile. Leaves linear, lance-shaped, opposite, without stalks. Flowers during the summer, small, white, very numerous, borne on stiffish threadlike stalks.

Culture and Propagation.—Although this species may be increased by dividing the thickish roots in spring, it is as a rule better to raise the plants from seeds. These may be sown thinly out of doors in April and May in a warm and not too sunny border with finely prepared soil. As soon as the plants are large enough to handle easily they may be pricked out into another bed, afterwards keeping them well watered and shaded until established. By the end of September, or in mild weather in spring, the young plants may be moved to their flowering positions in the flower border. They will not bloom so well the first and second year as afterwards, but once established they produce immense clouds of blossom annually, and are very valuable for cutting for bouquets, room decoration &c., either in masses by themselves or mixed with other flowers.

G. perfoliata.—A perennial 1½-3 ft. high, native of S.W. Europe. Leaves smooth, lance-shaped, acute, more or less stem-clasping. Flowers in summer, pink, in forked clammy panicles.

Culture &c. as for *G. paniculata*.

G. repens.—This is a pretty perennial species 3-6 in. high, native of the European Alps, with smooth linear leaves, and white or rose-coloured flowers from July to September, borne in 3-forked corymb-like clusters.

Culture &c. as above for *G. paniculata*. A very useful plant for the rockery.

G. scorzoneraefolia.—A Crimean perennial 1-3 ft. high. Leaves lance-shaped acute, more or less stem-clasping, 3-5-nerved and 3-4 in. long. Flowers from July to September, white, numerous, in slightly clammy panicles.

Culture &c. as above for *G. paniculata*.

G. Steveni.—A Caucasian perennial 1-2 ft. high, with linear lance-shaped, keeled, gray leaves, nearly all radical. Flowers

from July to September, white, paniced; petals broadly linear, blunt, not notched.

Culture &c. as above for *G. paniculata*.

G. viscosa.—This pretty annual is a native of the East. It resembles *G. elegans* in height and appearance, and has been considered simply as a rosy-flowered form of that species. It differs, however, in having a more blue-green appearance and more knotted and leafy stems. The flowers are borne on shorter and more erect stalks, and are white flushed with rose, and slightly fragrant. There are other minor differences, among which may be mentioned the clamminess of the stems, and the somewhat broader and rather stem-clasping leaves.

Culture &c. as above for *G. elegans*.

SAPONARIA (FULLER'S HERB; SOAPWORT).—A genus containing about 30 species, some of which are annual, with a habit like the *Gypsophilas*, and some perennial with growth like the *Silenes*. Calyx ovoid or oblong tubular, 5-toothed, obscurely nerved. Petals 5, narrow-clawed, with an entire or notched blade, scaly or not at the base. Stamens 10. Styles 2 or very rarely 3.

Culture and Propagation.—Saponarias grow well in sandy, loamy, well-drained soil and may be utilised in the rock garden, borders, edges of shrubberies, waste places, old banks &c. The perennial species are easily increased by seeds or by dividing the roots. The seeds of annual and biennial kinds should be sown in April and May in the places where the plants are to bloom, or earlier in the year on a hotbed or warm greenhouse, afterwards transferring the seedlings to the open air about the end of May.

S. cæspitosa.—A pretty alpine perennial 3-6 in. high, native of the Pyrenees. Leaves in dense tufts, smooth, rather thick, linear, rough at the edges, keeled behind. Flowers in summer, bright rose, somewhat umbellate; petals obovate, entire, with 2 awl-shaped scales at the throat.

Culture &c. as for *S. officinalis* below. This species makes a good carpeting beneath taller plants, but although it likes shade and shelter must not be suffocated with coarser plants.

S. calabrica.—A beautiful annual 6-12 in. high, native of Calabria, with erect, forked stems. Leaves obovate spoon-shaped, usually 1-nerved, smooth or

slightly downy, with ciliated edges. Flowers in late summer, beautiful rose, with rounded petals, narrowed at the base, and borne on forked branches. The inflated reddish calyx is usually hidden by the upper leaves after flowering. There is a variety with white flowers, and a dwarf compact one with deep rose ones.

Culture and Propagation.—Seeds of this species and its varieties may be sown in gentle heat in March, afterwards pricking out the seedlings into shallow boxes, and growing them on under glass until the end of May, when they may be placed out of doors in masses, allowing about 6 in. apart each way between every plant. Seeds may also be sown out of doors in April and May where the plants are to bloom. When the seedlings are large enough, they may be thinned out about 6 in. apart as above. From the beginning to the end of September seeds may also be sown in the open border and the plants will survive an ordinary mild winter except in the bleakest parts of the kingdom. Plants raised from seeds sown at this period are much larger and bloom earlier the following year than those from spring-sown seeds.

S. glutinosa.—A biennial about 18 in. high, native of E. Europe, with ovate 3-nerved leaves. Flowers in summer, blood-red, with minute petals deeply notched at the apex and scales at the throat.

Culture &c. as above for *S. calabrica*.

S. lutea.—A pretty perennial 3-6 in. high, native of the Alps, with linear leaves ciliated at the base. Flowers from June to August, yellow, in heads; calyx woolly, with short lobes; petals obovate, entire; stamens more or less violet-coloured.

Culture &c. as for *S. officinalis* below.

S. ocymoides (*Rock Soapwort*).—A lovely trailing perennial native of S. and Central Europe, forming dense tufts 6-12 in. high, with forked branches. Leaves ovate lance-shaped, usually 1-nerved. Flowers from May to August, red or pink, in panicle clusters; calyx purple, cylindrical, hairy, and somewhat clammy.

The variety *splendens* has larger and more deeply coloured rosy flowers than the type, and is very effective used as an edging to taller plants, or in masses in the rock garden.

Culture &c. the same as for *S. officinalis*.

S. officinalis (*Bouncing Bet*; *Common Soapwort*).—A stout, vigorous and showy perennial 1-2 ft. high, native of Europe, Asia, and N. America, and also found in Britain in hedges, roadsides, fields &c. Leaves smooth, glaucous, oblong lance-shaped, 3-4 in. long, 3-nerved. Flowers in August and September, lilac or white, 1 in. across, with obcordate petals. *S. hybrida* is a variety with connate upper leaves, and a gamopetalous corolla. The variety *puberula* has the upper part of the stem and the calyx downy. There is also a double-flowered variety (*flore pleno*) with rather pale blossoms like a small Carnation.

Culture &c.—This species and its varieties, although perennial, may be raised annually from seeds in the same way as recommended for *S. calabrica* above. The double-flowered form, however, which rarely seeds, must be increased by dividing the roots in early autumn or in spring. The single-flowered forms may also be increased by division at the same period.

S. Vaccaria (*Cowherb*).—An annual 1-2 ft. high, native of Central Europe and occasionally found in British cornfields. Leaves ovate lance-shaped, without stalks. Flowers in July and August, red, paniculate; calyx smooth, 5-angled.

Culture &c. as above for *S. calabrica*.

SILENE (CATCHFLY; CAMPION).—A large genus containing according to Bentham and Hooker about 200 more or less distinct species, although as many as 400 have been described by other authors. They are annuals or perennials with erect, tufted, decumbent or diffuse-climbing stems with opposite entire leaves. Flowers solitary or rarely in cymes, often in one-sided spikes forming a terminal cluster or panicle. Calyx variously inflated, ovoid, bell-shaped, club-shaped, or tubular, 5-toothed or 5-cleft, usually 10-nerved. Petals 5, narrow-clawed, with an entire 2-cleft or rarely lacinated blade, often with 2 scales at the base. Stamens 10. Styles usually 3. Capsule opening at the apex by 6 (rarely 3) teeth or valves.

Culture and Propagation.—Silenes grow in almost any light loamy soil, and many of the dwarf kinds are very useful as rock-garden plants, while the taller kinds may find a place in the ordinary flower border. The perennial species may be increased by seeds, by cuttings, or

division of the root. The annual kinds, such as *S. pendula* and its variety *compacta*, are best from seeds sown late in summer. If transplanted not later than the end of September, they make good strong plants for spring flowering.

S. acaulis (*Cushion Pink*).—A very dwarf alpine herb tufted into light green masses like a wide-spreading moss, but quite firm. Native of the mountains of Scotland, Ireland, North Wales, the Lake district of England, and many other parts of Europe; found also in Asia and America. Leaves short, linear, smooth, crowded. Flowers in summer, pink, rose or crimson, on short stalks barely peeping above the leaves; petals obovate, slightly notched; calyx bell-shaped or tubular, quite smooth, with rather blunt teeth. *Alba* is a variety with white flowers; *excava*, with the flower-stems shorter than in the usual form; and *muscoides*, dwarfer still; but none of them are far removed from the common plant.

Culture and Propagation.—The Cushion Pink, as the popular name implies, is a charming little plant for making green carpets in the border or rock garden. It likes a well-drained soil composed of sandy loam, peat, and leaf soil, and also a partially shaded situation.

Seeds may be sown as soon as ripe in shaded parts of the border or in cold frames in pots or pans. The seedlings are pricked out when large enough, and are best wintered in cold frames in the bleakest parts of the kingdom. They may be planted out in mild weather in spring in such localities, but in warmer situations they will stand an ordinary winter if planted in September. The plants when well established in clumps may also be divided in September or in spring.

S. alpestris (*Alpine Catchfly*).—A dwarf and beautiful alpine herb, about 6 in. high, native of the Alps. Leaves linear-lance-shaped, bluntnish, tufted, smooth, erect; stem simple, few-leaved. Flowers in early summer, white, shining, rather large, panicked; petals 4-toothed; calyx erect, with blunt teeth, as long as the petals. Some varieties of this species are quite sticky from viscid matter, and others perfectly free from it.

Culture &c. as above for *S. acaulis*.

S. Armeria (*Sweet William Catchfly*). A smooth annual 12-18 in. high, native of France and Switzerland, with ovate-lance-shaped blue-green leaves rather heart-shaped at the base, borne on erect, knotty, forked stems which are somewhat clammy near the top. Flowers from July to September, pink, in corymbose panicles. The variety *alba* is readily distinguished by its white flowers, and there is another form with flesh-coloured blossoms.

Culture and Propagation.—The Sweet William Catchfly is a very ornamental border plant and grows well in almost any soil, so long as it is well drained and fairly sandy.

Seeds may be sown as soon as ripe in spots where the plants are to bloom, and the seedlings may be thinned out about 6 in. apart, in preference to pricking them out or transplanting. In cold parts of the kingdom it is advisable to sow the seeds in cold frames, and transplant the seedlings in spring. Seeds may also be sown in April and May out of doors in the same way as recommended for autumn.

S. Atocion.—A downy-stemmed annual 6-12 in. high, native of the Levant. Leaves roundish obovate, lower ones long-stalked, the uppermost ones sessile. Flowers in summer, pink, in more or less erect three-forked panicles. Petals obcordate, blunt, with a sharp tooth on each side at the base, crowned with 2 protuberances.

Culture &c. as above for *S. Armeria*. Increased by seeds.

S. chloræfolia.—A smooth-stemmed Armenian perennial 1-2 ft. high, with elliptic pointed leaves, the upper ones rather heart-shaped. Flowers in August and September, large, white, becoming reddish with age; calyx long, striped; petals cleft half way down with a 2-lobed crest.

Culture &c. as above for *S. acaulis*. Increased by seeds or division.

S. compacta.—A smooth, glaucous biennial about 18 in. high, native of Russia. Leaves ovate heart-shaped, without stalks, the two large ones beneath the flowers appearing almost connate. Flowers in summer, pink, or deep rose, crowded into dense corymbs; petals obovate, entire.

Culture and Propagation.—This is one of the most beautiful members of the

genus. It must be grown in a rich well-drained soil, as it cannot stand the wet and cold of winter. It must not however be grown in a soil that is too light and inclined to be dry, but rather in one with plenty of humus or decayed vegetable matter. In fairly mild parts of the kingdom seeds may be sown out of doors in autumn as soon as ripe, or in spring, in the same way as recommended for *S. Armenia*. In cold northern parts they are best sown in cold frames either in autumn or spring, afterwards moving the plants outside in mild weather in spring.

S. Elisabethæ.—A beautiful perennial 3–9 in. high, native of the Tyrolese mountains, with downy and clammy stems and leaves, the latter being 2–3 in. long, lance-shaped, acute. Flowers rather late in summer, $1\frac{1}{2}$ in. across, bright rose, the bases or claws of the wedge-shaped notched petals being white.

Culture &c. as above for *S. acaulis*. Increased by seeds or division. This species should be grown in a warm corner of the rockery, in deep soil composed of well-drained peat and loam.

S. fimbriata.—A downy perennial 2–4 ft. high, native of the Caucasus. Leaves large, ovate lance-shaped, wavy, on long stalks. Flowers from May to August, white, in large spreading panicles; petals fringed.

Culture &c. as above for *S. acaulis*. Increased by seeds or division.

S. Hookeri.—A Californian perennial with decumbent stems. Leaves downy, 2–3 in. long, the lower ones elliptic-spoon-shaped, narrowed into long stalks, the upper ones elliptic-lance-shaped, acute or pointed. Flowers in early summer, over 2 in. across, pink; petals variously lobed.

Culture &c. as above for *S. acaulis*. It requires a warm sheltered place in the rock garden and flourishes in rich sandy loam, peat and leaf soil.

S. inflata (*S. Cucubalus*).—This glaucous, smooth or downy perennial, 2–3 ft. high, is a native of the roadsides and waste places of Britain, and is popularly known as the Bladder Campion or Catch-fly, Cow Bell, White Ben, White Bottle. Leaves 1–3 in. long, ovate, obovate, or oblong. Flowers from June to August, $\frac{3}{4}$ in. across, drooping, white, some having stamens only, some pistils only, others both; petals deeply cleft; calyx bladdery,

net-veined. The variety *puberula* is a rarer form with downy leaves.

Culture &c. as above for *S. acaulis*. Increased by seeds or division.

S. lacera.—A procumbent hairy biennial, native of the Caucasus, with long-stalked, ovate-lance-shaped, wavy leaves. Flowers from May to August, white with jagged petals, and a much inflated calyx.

Culture &c. as above for *S. compacta*. Increased by seeds sown in early autumn or spring.

S. laciniata.—A downy perennial 3–4 ft. high, native of Mexico and California, with large lance-shaped, acute leaves. Flowers in summer, large, terminal, rather drooping, crimson, with a white, two-parted crest; calyx cylindrical, inflated; petals more or less 4-cleft.

Culture &c. as above for *S. acaulis*. Increased by seeds or division. This plant should be grown in the warmest part of the garden.

S. livida.—A flexuous, downy perennial 1 ft. high, native of Carniola, with oblong lance-shaped leaves. Flowers in summer, white above, purplish-green beneath, panicle, drooping to one side; petals 2-cleft, with scales.

Culture &c. as above for *S. acaulis*. Increased by seeds or division.

S. maritima.—A perennial species, native of British and W. European sea coasts, very similar in growth to the Bladder Campion, *S. inflata*. It has a blue-green appearance, the numerous stems being clothed with thickish oblong acute leaves, the edges of which are furnished with small spiny teeth. Flowers from June to August, white, larger than those of *S. inflata* and remarkable for the conspicuous blue anthers of the stamens; petals shortly cleft, the segments broad, with 2 scales at the base. The variety *flore pleno* has handsome double flowers rising slightly above the tufts of sea-green leaves.

Culture &c. as above for *S. acaulis*. The double-flowered variety can only be increased by dividing the roots or stems in spring.

S. monachorum.—A pretty Bosnian species very much resembling *S. quadrifida* in appearance. Its slender green stems, however, are furnished with

shorter, narrower, and blunter leaves, about $\frac{3}{4}$ in. long. The flowers are white and appear from June onwards. They have wedge-shaped petals with 4 blunt teeth, and resemble those of *S. alpestris*, *S. quadridentata*, and *S. quadrifida*.

Culture &c. as above for *S. acaulis*.

S. noctiflora.—An erect, soft, downy annual 1-2 ft. high native of sandy places in the British Isles. Leaves 3-4 in. long, oblong lance-shaped, acute, the lower ones stalked. Flowers in summer, erect, open at night, fragrant. Petals rosy within, yellow outside; calyx cylindrical, with 10 green nerves.

Culture &c. as above for *S. Armeria*. Increased by sowing seeds annually as soon as ripe, or in spring out of doors.

S. nutans (*S. paradoxa*).—*Nottingham Catchfly*.—A downy perennial with a woody rootstock, native of dry places, walls &c. in Britain and the Channel Islands. Stems 2-3 ft. high, clammy above. Lower leaves oblong lance-shaped, 2-5 in. long, tufted, stalked, the upper ones small, narrow, without stalks. Flowers from May to July, dimorphic, opening and fragrant for 3 nights, 5 stamens ripening on each of the two first nights, the styles protruding on the third. Calyx tubular, swollen in the middle. Petals white or pink, drooping.

Culture &c. as above for *S. acaulis*. Increased by seed or division.

S. orientalis.—A beautiful perennial about 2 ft. high, native of Eastern Europe. Leaves glaucous, ovate, pointed. Flowers in summer, deep rose, in dense umbel-like heads 3 in. across.

Culture &c. as above for *S. acaulis*. Increased by seeds or division.

S. pendula.—A downy trailing annual, native of Italy and Sicily, with ovate-lance-shaped leaves. Flowers in spring and summer, flesh-coloured, pendulous; calyx swollen, petals cleft. There are many varieties of this species, the best known being *compacta*, very dwarf, densely tufted, covered with beautiful pink flowers in spring; *compacta alba*, with white flowers; 'Empress of India,' 'Snow King,' 'Double Pink,' *ruberrima* and *ruberrima Bonnetti*, and 'Zulu King' (double) are other forms worth growing.

Culture and Propagation.—This Silene and its varieties grow 6-9 in. high,

and are very popular for spring bedding, especially as they soon make fine tufts, and produce their pretty flowers in great abundance. Seeds may be sown as soon as ripe in some spare part of the garden, and as soon as the beds and borders are cleared of the usual summer bedding plants, they may be filled with the young Silenes. It is better to get them planted at least before the middle of October, and not later than the middle of September for northern parts of the kingdom, as otherwise they will be unable to establish themselves before the frosty weather sets in. By planting early, good strong tufty plants will be obtained for flowering profusely in spring. For flowering during the summer months seeds may be sown in the open border in patches in April and May, afterwards thinning the seedlings out 6-9 in. apart.

S. pennsylvanica (*American Wild Pink*).—A beautiful downy N. American perennial 4-8 in. high. Lower leaves narrowly spoon-shaped, nearly smooth, tapering into hairy stalks; upper ones lance-shaped. Flowers in early summer, pink, clustered; petals wedge-shaped, slightly notched and jagged-edged.

Culture &c. as above for *S. acaulis*. Increased by seeds and division.

S. picta.—A pretty rush-like annual 1-2 ft. high, native of Asia Minor and Syria, with much-branched slightly downy stems. Lower leaves obovate spoon-shaped; upper ones linear, acute. Flowers in summer, pink, loosely paniced; calyx striped, and petals veined with red.

Culture &c. as above for *S. pendula*. Increased by seeds.

S. pumilio (*Pigmy Catchfly*).—A beautiful densely tufted perennial, 2-3 in. high, native of the Tyrol. Leaves shining green, linear or spoon-shaped, somewhat fleshy and blunt, and slightly downy. Flowers in summer, rosy, about an inch above the leaves; calyx swollen, hairy, many-nerved; petals obovate.

Culture &c. as above for *S. acaulis*. Increased by seeds or division.

S. pusilla.—A charming little plant, closely related to *S. quadrifida*. It has mossy foliage, and the white flowers are produced throughout the summer months on stalks 2-4 in. high.

Culture &c. as above for *S. acaulis*. It flourishes in moist sandy loam with a

little mortar rubbish in half-shady places in the rock garden. When it finds a favourable spot it reproduces itself readily from self-sown seed.

S. quadridentata. — A species closely related to *S. alpestris*. It grows 4-6 in. high, and forms dense masses of green linear oblanceolate leaves about $1\frac{1}{2}$ in. long. The flowers are freely produced in summer—from June onwards—in loose panicles, and are pure white with wedge-shaped 4-toothed petals.

Culture &c. as above for *S. acaulis*.

S. quadrifida.—A pretty loose-growing European species somewhat resembling *Gypsophila elegans* in appearance. It grows 3-6 in. high, its slender stems being furnished with linear leaves about $1\frac{1}{2}$ in. long. The white wedge-shaped flowers with 4 blunt teeth appear from June onwards in great profusion and are very attractive.

Culture &c. as above for *S. acaulis*.

S. regia (Royal Catchfly).—A downy perennial 3-4 ft. high, native of the S. United States. Leaves thickish, ovate lance-shaped, acute. Flowers in summer, deep scarlet, numerous, in clusters; petals spoon-shaped, lanceolate, mostly un-
divided.

Culture &c. as above for *S. acaulis*. Increased by seeds or division. Should be grown in a warm corner of the flower border.

S. Saxifraga.—A smooth, rather clammy tufted perennial, 3-6 in. high, native of the Alps, with acute linear leaves. Flowers from June to August, yellowish-white above, reddish beneath, and usually borne singly on very long stalks, but occasionally two or three on the same stem.

Culture and Propagation.—Owing to the thickness of its light green leaves this species is excellent for making a carpet under taller plants in the rockery or border, especially as it likes a certain amount of shade, but plenty of ventilation, and a light and rather sandy soil with a little leaf mould or peat.

Seeds may be sown as soon as ripe in the open border, and the young plants may be moved to their flowering positions before the end of September, or in mild weather the following spring. In cold northern parts, it is safer to sow in autumn in cold frames and plant out in spring. Seeds however may also be sown

out of doors in April and May for later blooming. The plants may also be divided when they have made good tufts in spring or early autumn, the distance between the replanted portions being 9 to 12 inches.

S. Schafta.—A pretty Caucasian perennial rarely exceeding 6 in. high. Leaves obovate, acute. Flowers from June to October, purple, erect, gradually covering the stems; calyx club-shaped, more than 1 in. long; petals wedge-shaped, small toothed.

Culture &c. as above for *S. Saxifraga*. Like the latter species *S. Schafta* is admirably suited for carpeting patches in the rock garden or border.

S. supina.—A tufted Caucasian perennial, with downy, clammy, woody stems. Leaves linear, acute. Flowers from June to August, white, on short alternate stalks; calyx long, cylindrically club-shaped, woolly; petals long-clawed, cleft.

Culture &c. as above for *S. acaulis*.

S. vespertina.—A beautiful downy annual 1 ft. high, native of Greece. Leaves spoon-shaped, acute, on ciliated stalks. Flowers in summer, rosy, all turned on one side of the raceme; calyx bladdery, club-shaped; petals 2-lobed.

Culture &c. as above for *S. compacta*, or *S. pendula*. Increased by seeds.

S. virginica (Fire Pink).—A downy perennial 1-2 ft. high, native of North America. Leaves thin, spoon-shaped, or the upper ones oblong, lance-shaped. Flowers in summer, 2 in. across, deep crimson, few and loosely cymose; calyx oblong cylindrical, becoming obconical; petals oblong, 2-cleft.

Culture and Propagation.—This species is best raised from seeds, as it takes a long time to recover if divided. It should have a particularly well-drained position in the rockery or border, as wetness at the root in winter is more or less injurious to it.

S. Zawadski.—A pretty Galician perennial with rosettes of radical lance-shaped acute leaves, and slender erect flower stems 6-8 in. high, bearing forked clusters of white flowers from May to July. The roundish petals are furnished with 2 linear scales at the base.

Culture and Propagation.—This species requires the same treatment in every way as *S. Saxifraga* and *S. Schafta*, above.

LYCHNIS (ROSE CAMPION).—A genus containing about 30 species of beautiful annual or perennial herbs, often erect, with the habit of *Silene*, from which it differs chiefly in the flowers having more numerous styles—5 instead of 3. Calyx inflated, ovoid, or club-shaped, tubular, 5-toothed, 10-nerved. Petals 5, narrow-clawed, with entire 2-cleft or lacinated blades, often with 2 scales at the base. Stamens 10. Styles 5, rarely fewer.

Culture and Propagation.—The Campions are easily grown and thrive in a light, rich, loamy soil. They may be increased by dividing the rootstocks in autumn or spring, or by seeds. They are brilliant objects in the border, and are very useful for the great quantity of flowers they afford for cutting.

The species described below are all perennial except where otherwise mentioned.

L. alpina. — A smooth British and European plant, 4–6 in. high, with crowded narrow linear-lance-shaped leaves 1–2 in. long. Flowers in early summer, about $\frac{1}{2}$ in. across, rosy-pink, in compact heads; petals narrow, deeply cleft.

Culture &c. as for *L. chalconica*. Best increased from seeds and with more difficulty by division. This dwarf plant is excellent for carpeting patches in the rockery. It likes partially shaded spots and light sandy soil.

L. chalconica. — A handsome and striking species $1\frac{1}{2}$ – $3\frac{1}{2}$ ft. high, native of Russia. Leaves lance-shaped, somewhat heart-shaped at the base, hairy, stem-clasping. Flowers in summer, bright scarlet, in dense heads; calyx round, club-shaped, ribbed. There is a white-flowered form called *alba*, and also a double-flowered one called *flore pleno*.

Culture and Propagation.—There are many varieties of this fine species, including double red and double white forms. The single-flowered varieties are on the whole best increased from seeds, although they may be also multiplied by division. The seeds may be sown as soon as ripe out of doors in the milder parts of the kingdom, or in cold frames in unfavourable localities. The same remarks apply to spring sowing, but if the plants are required to bloom the same year, it is better to sow the seeds in gentle heat, and have the seedlings grown on and hardened off, so as to be fit for planting in the open

border by the end of May or beginning of June.

The double-flowered forms—both scarlet and white—can only be increased by dividing the plants, as they very rarely produce any seeds at all. Division is best done in early autumn, before the end of September, or in mild weather in spring.

The double-flowered kinds are somewhat less vigorous than the single-flowered ones, and are best left undivided if doing well, for at least two or three years, or even more according to circumstances. Splendid tufted plants are produced on well-manured and well-drained loamy soil.

L. Cœli-rosa (*Agrostemma Cœli-rosa*). *Rose of Heaven*. — An annual species about 1 ft. high, native of the Levant. It has tufts of much-branched stems clothed with bright green linear lance-shaped leaves. Flowers during summer, delicate rose, bright purple in the type, with obovate petals having white scales at the base.

The variety *fimbriata* (also known as *nana*) grows about 9 in. high, and has fimbriated petals. There is also a form of *fimbriata* called *lilacea* having pale lilac blossoms, the plant itself densely tufted and very free-flowering. The white-flowered form resembles the type in every way, with the exception of colour. The variety *purpurea* is compact in habit, with deep purple flowers.

Culture and Propagation.—Being an annual, the *Rose of Heaven* and its varieties are raised from seed sown annually, either in early autumn in cold frames, or in the open border about April and May, according as early or late flowering is required. The seedlings may be thinned out about 6–8 in. apart when the seeds are sown out of doors in the flowering patches.

L. coronaria (*Agrostemma coronaria*). A species 2–3 ft. high, native of S. Europe, with broadly lance-shaped, leathery leaves, 3 in. long, covered with a whitish woolly down. Flowers in July and August, about $1\frac{1}{2}$ in. across, crimson-red, calyx somewhat bell-shaped, ribbed, petals notched. The variety *atrosanguinea* has fine dark crimson-red flowers. White-flowered and double red-flowered forms are sometimes seen.

Culture and Propagation.—*L. coronaria* and its varieties are excellent border

flowers, and are very valuable for cutting. The plants may be increased much in the same way as recommended for *L. chalcidonica*, either by seeds sown in autumn or spring, in cold frames or in the open border according to locality; or by dividing the plants in early autumn or spring. Better plants are however, as a rule, obtained from seeds.

L. dioica (*L. diurna*).—*Bachelor's Buttons*; *Red Campion*.—A native of damp copses, hedgebanks &c. in the British Islands, and also found in Europe, Siberia &c. Stems softly hairy, rarely quite smooth, clammy above, 1-3 ft. high. Lower leaves 3-6 in. long, obovate, stalked; upper ones narrower. Flowers from spring to autumn, purple-rose, usually dioecious in wild specimens—that is, the male flowers are on one plant, the females on another; calyx very hairy, reddish. The double-flowered variety is very attractive. It flowers incessantly and is a fine border plant.

Culture and Propagation.—The double-flowered variety being seedless it may be increased by simply dividing the rootstocks in autumn or spring. The single form however may be increased either by seeds or division in the same way as recommended for *L. chalcidonica*.

L. Flos-cuculi (*Cuckoo Flower*; *Ragged Robin*).—A somewhat rough-stemmed plant 1-2 ft. high, native of moist meadows, copses, cornfields &c., in the British Islands. Lower leaves stalked, oblong lance-shaped, pointed, the upper ones narrow. Flowers in May and June, drooping, rosy, rarely white, petals with 4 linear segments; calyx purplish-red, with ten darker ribs. The double-flowered variety (*flore pleno*) is superior to the type and is more highly valued as a garden plant.

Culture and Propagation.—The *Ragged Robin* flourishes in any good and well-drained garden soil, and prefers rather damp and shaded situations. It is useful for planting under tall trees or near the edges of pieces of water, or in damp shaded parts of the rockery. For cutting purposes the flowers of both the double and single kinds are very useful.

Seeds of the single variety may be sown either as soon as ripe, or in spring as recommended for *L. chalcidonica*, but the plants may also be increased by dividing the roots about the end of Sep-

tember or in spring. The double-flowered variety can only be increased by division in this way.

L. Flos-jovis (*Agrostemma Flos-jovis*).—*Flower of Love*.—A Swiss plant 12-18 in. high, with woolly lance-shaped, stem-clasping leaves. Flowers in summer, purple or scarlet, in umbel-like heads. Calyx cylindrical, club-shaped; petals 2-lobed.

Culture and Propagation.—Although a true perennial this species is as a rule better raised from seeds in the same way as *L. coronaria*. The plants, however, may be also divided in spring or autumn. They like a sandy well-drained loam.

L. fulgens.—A Siberian perennial 6-12 in. high, with ovate lance-shaped, hairy leaves. Flowers in spring and summer, bright vermilion, large and handsome; petals 4-cleft; outer divisions awl-shaped; calyx cylindrical, woolly.

Culture and Propagation.—This brilliant species requires to be grown in rich and well-drained turfy loamy soil, or well-manured garden mould, as it sometimes fails to establish itself if neglected. Seeds are freely produced, and may be sown as soon as ripe in cold frames, afterwards pricking the seedlings out and growing them on in the frames until mild weather in spring, when they may be planted out in the open border. Here they should be grouped in bold masses for effect, each plant being 6-9 in. away from the next. The plants may be increased by division about September, or in spring, and also by means of cuttings of the young shoots. The latter are best taken in spring, and inserted in light sandy soil, and placed on a gentle hot-bed until rooted. They are afterwards potted up singly, and when established are hardened off for planting out.

L. grandiflora.—A Chinese species 8-12 in. high. Leaves ovate, almost stalkless, smooth. Flowers from June to August, brick-red or scarlet, about 2 in. across, with spreading lacerated petals, and an inflated calyx.

Culture and Propagation.—This beautiful perennial is not quite hardy in all parts of the kingdom, and hence may require some little protection with bracken or dried leaves &c. in the colder and more northern parts in severe winters. It likes a well-drained sandy loam and peat or leaf soil, and a warm, sheltered and

partially shaded situation in the rock garden or flower border. If seeds are produced they may be sown as recommended for *L. fulgens* above. Failing them, the plants may be divided about the middle or end of September, and replanted about 9 or 12 in. apart in masses. Division may also take place in spring, but does not as a rule succeed so well as when done in early autumn. Cuttings of the young shoots may also be rooted like those of *L. fulgens*.

L. haageana.—This fine plant is supposed to be a hybrid between *L. fulgens* and *L. coronaria* or *L. grandiflora*. It has shaggy stems, 1–2 ft. high, and large lance-shaped, pointed, hairy leaves purple-brown beneath. Flowers in summer, 2 in. or more across, bright scarlet. Petals broadly obovate, somewhat deeply notched, and with 2 awl-shaped teeth at the side. Calyx shaggy, swollen, and angled.

There are several varieties varying in colour from scarlet to pure white, the intermediate shades being rose, salmon, pink &c. The form known as *grandiflora* has very fine and brilliant flowers of various shades, and that known as *nana* represents a somewhat dwarfer and more compact race.

Culture and Propagation.—This is undoubtedly one of the finest, most showy border perennials. It flourishes in ordinary good and well-drained garden soils. It however prefers a mixture of peat and loam, and may be massed in front of Rhododendrons, Azaleas, and other Ericaceous plants. *L. haageana* and its varieties may be increased by sowing seeds as soon as ripe, or in spring, in the way recommended for *L. chalcidonica* or *L. fulgens*, and plants obtained in this way present a great variety of shades of colour. Any choice or rare variety however may be increased by division in early autumn or spring, and also by means of cuttings of the young shoots, in the same way as recommended for *L. fulgens* and *L. grandiflora*.

L. Lagasæ (*Petrocoptis pyrenaica*). A beautiful Pyrenean species about 3 in. high. Leaves obovate or oblong, rather leathery, and slightly glaucous. Flowers in spring and summer, bright rose, less than 1 in. across, with a white centre. This is a fine tufted plant for sunny parts of the rock garden.

Culture &c. as for *L. alpina* above.

L. oculata (*Viscaria oculata*).—A lovely Algerian annual, 6–18 in. high, forming compact and free-flowering tufts. Leaves glaucous lance-shaped acute, becoming narrower up the stems. Flowers in summer in great profusion, pinkish-purple, the notched petals having a deep purple spot at the base. Calyx suddenly contracted below the middle.

There are several desirable varieties such as *cardinalis*, bright crimson-purple; *cærulea*, bluish; *alba*, white; *Dunnetii*, rose; *splendens*, scarlet; *elegans picta*, crimson-purple edged with white; and *nana*, a dwarf about 9 in. high with flowers of various shades, rose, purple, and white.

Culture &c. as above for *L. Cæli-rosa*.

L. Presli.—A native of Poland, 12–18 in. high. Lower leaves numerous, in rosettes, ovate-lance-shaped, or obovate pointed, prolonged down the stem; upper leaves ovate, abruptly pointed, entire, much veined, deep green. Flowers in summer, purplish or carmine-rose, about 1 in. across, opening in the daytime, numerous produced in forked panicle clusters, and having reddish bracts; the corona in the centre is fringed, satiny and rose-white; calyx reddish, much swollen.

Culture &c. as above for *L. Haageana*.

L. pyrenaica.—A Pyrenean species, 3–4 in. high. Leaves glaucous, leathery, lower ones spoon-shaped, those of the stem heart-shaped, sessile. Flowers in summer, pale flesh colour, about $\frac{1}{2}$ in. across, in forked clusters. Petals slightly notched; calyx bell-shaped.

Culture &c. as above for *L. alpina*.

L. Sieboldi.—A handsome Japanese species about 1 ft. high. Leaves sessile, lower ones oblong, closely set, the others ovate-oblong acute, entire, soft and downy. Flowers in summer, large pure white, with wedge-shaped irregular slightly notched petals with jagged edges.

Culture &c. as above for *L. grandiflora*.

L. vespertina (*L. alba*).—*White Cam-pion*.—A British and European species 1–3 ft. high, with swollen-jointed purplish stems. Leaves connate, ovate-oblong, pointed, tapering at the base, hairy, the lower ones stalked, the upper ones sessile. Flowers from May to August, white, slightly scented in the evening. Calyx

over $\frac{1}{2}$ in. long, hairy, ribbed; petals cleft. The double-flowered variety *flore-pleno* is best known, and is more highly valued for the flower garden. It is an excellent border plant and has large white flowers that are very useful for cutting.

Culture &c. as above for *L. divica*. The double-flowered variety must be carefully divided when it is wished to increase the stock.

L. Viscaria (*German Catchfly*).—A handsome evergreen 10-18 in. high, native of Britain, Europe &c., with smooth erect stems, clammy at the nodes. Lower leaves 3-5 in. long, grass-like, with stalks downy at the margins. Flowers in early summer, almost sessile, with obovate red-purple notched petals. Calyx $\frac{1}{2}$ in. long, purple, swollen upwards.

There are several varieties, among which *alba*, white, *splendens*, deep red, and the double-flowered form (*flore-pleno*) with rosy-pink blossoms are best known.

Culture and Propagation.—This species and its varieties, especially the beautiful double-flowered ones, are excellent border or rock plants, and when grown in masses produce a very striking effect when in blossom. The single-flowered varieties produce seeds in abundance, and may be increased by that means in the same way as *L. haageana* or *L. chalcidonica*. They are also very readily multiplied by dividing the tufts in early autumn or in spring, and this is the only way that the double-flowered forms can be increased, besides cuttings of the young shoots in spring in the same way as mentioned under *L. fulgens*.

CERASTIUM (MOUSE-EAR CHICKWEED).—A genus containing according to some authors about 100 species, but reduced to about 10 by Bentham and Hooker. Chiefly downy or hairy, rarely smooth, annual or perennial herbs. Leaves various, but rarely awl-shaped. Flowers in terminal, forked, sometimes leafy, sometimes almost naked, cymes. Sepals 5, rarely 4. Petals equal in number, notched or 2-cleft, very rarely entire or lacinated, sometimes minute. Stamens 10, or fewer by abortion. Styles 5, rarely 4 or 3, opposite the sepals. Capsule cylindrical or cylindrical-conical, often incurved.

Culture and Propagation.—All the *Cerastiums* grow readily in ordinary garden soil. They are easily increased by

division in early autumn or in spring; or by cuttings in the open border in a shady place during the summer and autumn months. Seeds are freely produced by many kinds, and may be sown as soon as ripe in pots or pans of well-drained soil, and placed in cold frames during the winter months. The seedlings should be pricked out when large enough to handle into other boxes or pans, and should have as much light and air during the winter as possible and on all favourable occasions. They will be strong and sturdy for planting out in spring. Of the perennial species described below, *Biebersteini*, *grandiflorum*, and *tomentosum* are most generally grown on account of their attractive silvery foliage. They are effective for borders and edgings, and contrast forcibly with the brighter colours of other plants. They are also useful for massing in the rockery, and most of the species like an open and sunny situation.

C. alpinum.—A British species 2-4 in. high. Leaves ovate elliptic or oblong, covered with long silky hairs, or smooth. Flowers in summer, white; panicles rather hairy, few-flowered. There are several forms, the best known perhaps being *lanatum* and *villosum*.

Culture &c. as above. This species seeds freely.

C. Biebersteini.—An evergreen species about 6 in. high, native of Tauria. Stems branching, with woolly ovate-lance-shaped leaves. Flowers in early summer, white, on erect forked stalks.

Culture &c. as above.

C. Boissieri.—A Spanish species 4-12 in. high, with sessile silvery leaves, usually ovate-lance-shaped, acute, entire. Flowers in early summer, white, large, in regular forked cymes.

Culture &c. as above.

C. decalvans.—An interesting plant, native of Servia. It has trailing and rather woody stems, and dense rosettes of green leaves covered with tufts of wool. The numerous pure white flowers appear in May and June.

Culture &c. as above.

C. grandiflorum.—A strong-growing deciduous species about 6 in. high, native of E. Europe. Leaves narrow, acute, hoary or woolly, with somewhat revolute margins. Flowers in summer, white,

large, conspicuous, 7-15 on an erect stalk.

Culture &c. as above.

C. latifolium.—A deciduous European species 3-6 in. high, with ovate slightly stalked leaves, pale green or slightly glaucous. Flowers in summer, large, white, solitary, or on sparingly forked stalks.

Culture &c. as above.

C. purpurascens.—A remarkable species, native of the alpine regions of the Caucasus. It has a bulbous rootstock from which spring stems $2\frac{1}{2}$ - $3\frac{1}{2}$ in. long, furnished with oblong linear-lance-shaped leaves. The rather large flowers appear in summer and are of a beautiful blue, which contrasts well with the purple sepals.

Culture and Propagation.—This is a very effective plant in the rock garden when in blossom. It will grow in well-drained soil in sunny situations, but can be increased only by means of seeds sown in the way advised above. As neither runners nor side shoots are produced from the central stock it cannot be increased by division.

C. tomentosum.—A beautiful and well-known evergreen species, 6 in. high, native of S. and E. Europe. Leaves silvery and oblong, spoon-shaped, upper ones lance-shaped. Flowers in early summer, white, in forked cymes on erect stalks. This species is extensively used as an edging for beds, borders, banks &c.

Culture &c. as above.

ARENARIA (SANDWORT).—A genus of more than 130 species of annual or perennial herbs, sometimes slender or stiffish with small awl-shaped leaves, sometimes spreading or tufted with broader leaves. Flowers terminal, cymose-paniculate, or capitate, rarely axillary or almost solitary. Sepals 5, rarely 4. Petals equal in number, white, or very rarely red, entire or slightly notched, or rarely absent. Stamens 10, rarely 8 or fewer by abortion. Styles 3, seldom 2, or 4-5 in some flowers.

The plants known as *Alsine* are now referred to this genus.

Culture and Propagation.—The Arenarias are pretty little plants, chiefly suitable for the rock garden in more or less exposed situations, in ordinary soil. The perennial species, which only are worth growing, may be increased by division in early spring or autumn; by

seeds sown in spring in a cold frame; or by cuttings put under a bell-glass during the spring and summer months, keeping them shaded until fairly well rooted. The following are some of the best Sandworts.

A. balearica.—A pretty perennial Sandwort, native of Corsica, with very small ovate, shining, rather fleshy, ciliated leaves. Flowers in early summer, white, numerous, borne on purple or violet stalks 1-3 in. high.

Culture and Propagation.—This is an excellent plant for covering the faces of rocks or stones, as the tiny foliage almost adheres to the surface, making it a mass of deep shining green with scarcely an interstice. It likes open, airy, and partially shaded situations with plenty of moisture. If exposed to hot sunshine and drought it soon becomes parched and withered.

Seeds are freely produced, and though minute may be saved with comparative ease if picked before the pods are ripe enough to burst. The seeds may be sown as soon as ripe in pots or pans of fine sandy soil, and require scarcely any covering. They must be kept shaded and moist, and when the tiny seedlings are well above ground, they may be pricked out into similar pots and pans, and wintered in cold frames until spring.

An easier method of increase however is by dividing the plants at any time during the summer months. The divided portions should be placed on fine soil, and have a little soil sprinkled here and there over the patches to hold the plants down. If kept shaded and moist they will soon root, and may be placed in the rockery.

A. ciliata.—A procumbent, tufted evergreen species, 2-3 in. high, native of Ireland, the Orkney and Shetland Isles, Europe &c. Leaves small, ovate, downy, fringed with hairs near the base. Flowers in summer, about $\frac{1}{2}$ in. across, white, with spoon-shaped petals.

Culture &c. as above.

A. graminifolia.—A tufted evergreen grassy Caucasian plant 6-10 in. high. Leaves long, awl-shaped, rough-edged. Flowers in summer, white, on erect stalks; petals obovate, 5-6 times longer than the blunt sepals.

Culture &c. as above.

A. grandiflora.—A native of France, 3-6 inches high. Leaves awl-shaped, by

3-nerved, fringed with hairs, lower ones crowded. Flowers in summer, white, usually solitary, on long downy stalks. The variety *biflora* has two flowers on a stem, and *triflora* three.

Culture &c. as above.

A. laricifolia.—A Swiss species about 6 in. high, with awl-shaped leaves tooth-letted and ciliated on the edges. Flowers in summer, white, 1, 3, or 6, borne on rather rough upright stems.

Culture and Propagation.—This species is suitable for rockeries or border edgings, and flourishes in light sandy soil in sunny situations. It is easily increased by division of the tufts in early autumn or spring, or may be raised from seeds in the same way as *A. balearica*.

A. longifolia.—A Siberian species 6–9 in. high, with awl-shaped, thread-like, serrulated leaves. Flowers in summer, white, crowded on three-forked smooth panicles.

Culture &c. as above.

A. montana.—A handsome species about 3 in. high, native of France and Spain. Leaves lance-shaped linear, borne on very long stems, procumbent. Flowers in summer, white, large, over an inch across, solitary, on long stalks.

Culture &c. as above. As an ornamental plant for hanging over the faces of rock in half-shaded places in the rockery, *A. montana* is superior to any other species of *Arenaria*. Its loose and elegant and numerous white flowers make it a charming picture in suitable positions. It is easily increased by cuttings made in April and May, and inserted in sandy soil in shaded spots. Seeds are also freely produced and may be sown when ripe or in spring.

A. peplodes (*Honkenya peplodes*).—*Sea Purslane.*—A native of British seashores, 3–4 in. high, with rather fleshy, ovate-acute, recurved leaves. Flowers from May to August, $\frac{1}{4}$ in. across, white. Petals of the staminate flowers as long as sepals; of the pistillate flowers shorter.

Culture &c. as above.

A. purpurascens.—A closely tufted evergreen species, about 6 in. high, found abundantly on the higher Pyrenees. Leaves smooth, ovate lance-shaped, pointed, stalkless. Flowers in early summer, purplish, numerous, borne on downy stalks.

Culture &c. as above.

A. rotundifolia.—A Siberian species 4–6 in. high. Leaves about $\frac{1}{4}$ in. across, roundish, ciliated, on tufted branches. Flowers in summer, white, solitary, with roundish ovate petals.

Culture &c. as above.

A. tetraquetra.—A distinct looking tufted species about 6 inches high, native of the French Mediterranean shores. Leaves ovate, edged with a white cartilage, and fringed at the base. Flowers in summer, white, in heads, with narrow leaves between.

Culture &c. as above.

A. verna.—A native of dry rocks, pastures, banks &c. in the British Islands, and also found in Central Europe, N. Africa, and N. America. It is 1–3 in. high, with densely tufted 3-nerved awl-shaped leaves. Flowers in early summer, $\frac{1}{2}$ in. across, white, with greenish centres, freely produced. The variety *caespitosa* has very leafy stems, smooth calyx and flower stalks. In the variety *Gerardi* the leaves do not end in a small point.

Culture &c. as above.

SAGINA (PEARLWEED; PEARLWORT).—A genus of about 8 small tufted annual or perennial herbs, with awl-shaped leaves, and small, usually long-stalked flowers. Sepals 4–5. Petals 4–5, entire, or slightly notched, sometimes minute or absent. Stamens equal in number to the sepals, or twice as many, or fewer by abortion. Styles equal in number to the sepals and alternate with them.

Culture and Propagation.—The Pearlworts being mostly weeds, the species mentioned below is the only one worthy of notice as a garden plant. It may be raised from seed sown in May, and increased in the autumn by dividing the patches. For making a green carpet or edging to a border it is very useful, and great hopes were at one time entertained of its value for making lawns, but with the greatest care it becomes too patchy for this purpose.

S. pilifera (*Spergula pilifera*).—A tufted moss-like plant, about 2 in. high, native of Corsica. Leaves linear, awl-shaped, smooth. Flowers in summer, small, white; petals twice as large as the oblong blunt sepals. The variety *aurea* has golden-yellow foliage, and is more or less used for carpet bedding.

Culture &c. as above.

XX. PORTULACEÆ—Purslane Order

An order containing about 15 genera and 125 species of succulent herbs or undershrubs, often smooth, but sometimes hairy. Leaves alternate, seldom opposite, entire, often fleshy. Stipules scarious, sometimes lacerated, or changed into hairs, or absent. Flowers solitary, at the ends of the branches, racemose, cymose, or paniculate, the lower ones axillary or lateral. Sepals usually 2, rarely 5, free, or adnate to the base of the ovary, much imbricated, persistent or deciduous. Petals 4-5, rarely numerous, hypogynous or rarely perigynous, free, or connate at the very base, imbricate, entire, often fleeting or deliquescent. Stamens inserted with the petals, often adnate to them at the base, sometimes equalling them in number, sometimes fewer and opposite, sometimes numerous; filaments thread-like, distinct. Carpels 3 or more; stigmas several, much divided.

PORTULACA (PURSLANE).—A genus containing about 16 species of spreading or ascending fleshy herbs, with alternate or nearly opposite flat or rounded leaves, often with tufts of bristles in the axils, the upper ones often forming an involucre round the flowers. Sepals 2, cohering in a tube and adnate to the base of the ovary, free above, deciduous. Petals 4-6, free, or slightly connate at the base. Stamens 8 or more, at the base of the petals, and with them perigynous. Style deeply cut into 3-8 branches.

Culture and Propagation.—Outdoor Portulacas are best treated as annuals. The seeds may be sown thinly in April in pans in a cold frame. By June the seedlings will be ready for planting out. If pricked off into pots or pans previously and kept in a well-aired frame the seedlings make much better plants. Seeds may also be sown in the open border about the end of May, to bloom later than those raised under glass.

The double-flowered varieties may be increased by means of cuttings during the summer and autumn months, but this process necessitates keeping the plants under glass during the winter period. The cuttings should be inserted in light sandy soil and may be rooted in a shaded part of the garden, out of doors or under a handlight; or if the season is unfavourable on a gentle hotbed.

Portulacas are not particular as to soil, but rich loam and leaf mould suit them best. They should be planted in the sunniest and warmest parts, and in bold masses to secure better effect when in bloom. The best kind to grow is:

P. grandiflora (*Sun Plant*).—A beautiful Brazilian plant, about 6 in. high, with cylindrical, acute leaves, having tufts of hairs in the axils. Flowers in summer, crimson-purple, three or four together, crowded, surrounded by whorls of leaves and crowded hairs. The variety *Thellusoni* is a taller plant, with less cylindrical and blunter leaves than the type, and large scarlet flowers, with 2-lobed petals. There are several forms such as *aurea*, *aureo-striata*, *alba*, *coccinea*, *splendens*, *caryophylloides*, *Thornburni*, *aurantiaca*, *Bedmanni* &c., with single flowers of various hues, and most of them are obtainable from a packet of mixed seed. The variety called *plena* has beautiful double flowers of a brilliant crimson-purple, and looks very handsome.

The popular name of 'Sun Plant' is derived from the fact that the flowers open as a rule only during bright sunshine; hence the necessity for planting in warm sunny positions to obtain the best results.

Portulaca oleracea, an Indian annual, is sometimes grown as a salad, the leaves being eaten fresh or in a cooked state.

CALANDRINIA (ROCK PURSLANE). A genus containing about 60 species of smooth or hairy annual or perennial herbs, sometimes shrubby at the base. Leaves alternate or tufted, rather fleshy. Flowers solitary, long-stalked, or axillary, or in loose terminal racemes or contracted heads. Sepals 2, herbaceous, ovate, persistent, or rarely deciduous. Petals 5, often ephemeral, rarely fewer or numerous, hypogynous. Stamens 5 or more, free, cohering into a ring at the

base, or adhering to the petals. Capsule globose or ovoid, 3-valved.

Culture and Propagation.—The species described below are the ones chiefly grown as annuals from seed, except *C. umbellata*, which is treated as a biennial. They like a light sandy soil in warm places in the rock garden. As the plants do not transplant well, it is better to sow seeds where the plants are to flower, protecting them with handlights or sheets of glass until all danger of frost is over. The flowers of most species expand only in bright sunshine, thus resembling the Portulacas.

C. discolor.—A Chilean plant 12–18 in. high, with fleshy obovate leaves, narrowed at the base, pale green above, purple beneath. Flowers in summer, bright rose, $1\frac{1}{2}$ in. across, with a yellow tuft of stamens in the centre, borne on long racemes. The blossoms are at first drooping, but become erect when fully expanded. This species is often called *C. elegans* in gardens.

Culture &c. as above. Seeds may be sown in the open border in warm sheltered situations, with plenty of sunshine, in April and May, and even as late as the end of June, to secure a succession of flowering till late in autumn. The seedlings when large enough may be thinned out 6–8 in. apart.

C. grandiflora.—A native of Chili 1 ft. high, with rather shrubby stems. Leaves fleshy, rhomboid, acute, stalked. Flowers in summer, 2 in. across, rosy, in loose racemes; calyx spotted with black.

Culture &c. as above.

C. Menziesi (C. speciosa).—A Californian species with much-branched stems at first prostrate, but afterwards turning upwards 12–18 in. high. Leaves spatulate, much narrowed towards the base. Flowers from June to September, deep purple-crimson, $\frac{1}{2}$ –1 in. across.

Culture &c.—This is one of the most beautiful members of the genus and looks very effective grown in large patches. Seeds may be sown at intervals from April to July to keep up a succession of blossom.

C. nitida.—A pretty tufted species about 6 in. high, native of Chili. Leaves smooth, oblong, spatulate, sub-acute, narrowed at the base. Flowers in sum-

mer, rosy, about 2 in. across, and borne in many-flowered leafy racemes.

Culture &c. as above for *C. discolor*.

C. oppositifolia.—A pretty Californian species with a thick and fleshy tuberous rootstock, and oblanceolate leaves 2–2 $\frac{1}{2}$ in. long. The pure white or bluish flowers, each about $1\frac{1}{2}$ in. across, are borne in late summer, 3 or 4 on a stem 3–6 in. high. The sepals are roundish and sharply toothed, as are also the 5 deeply cleft petals, surrounding a cluster of about 20 stamens in the centre.

Culture &c. as for *C. umbellata* below. This species is rather tender and is best wintered in a cold greenhouse in unfavourable parts of the kingdom. *C. Tweedyi*, a dwarf-tufted species with thick fleshy leaves and bronzy flesh-coloured flowers, would probably succeed if treated in the same way, at least in the milder parts of the kingdom.

C. umbellata.—A distinct and pretty Peruvian species about 6 inches high, with radical, linear, acute, hairy leaves. Flowers in summer and autumn, brilliant magenta-crimson, less than 1 in. across, in many-flowered cymose corymbs.

Culture and Propagation.—This species is a perennial on dry soils, and may be grown in warm fully exposed sunny parts of the rock garden. The seeds should be sown in fine sandy soil in pots or in the open some time during September, or in April and May as mentioned above for *C. discolor*. If sown in pots the seedlings should not be pricked out, as they are apt to perish by such treatment, but the whole potful—soil and all—should be carefully planted without breaking the soil. In favourable parts of the kingdom this species and also *C. grandiflora* will often reproduce themselves from self-sown seeds.

CLAYTONIA.—A genus containing about 20 species of fleshy annual or perennial herbaceous plants, usually smooth, sometimes with tuberous rootstocks. Lower leaves stalked, upper ones alternate or opposite. Stipules none. Flowers in terminal racemes or cymes, rarely axillary or solitary. Sepals 2, herbaceous, ovate, persistent. Petals 5, hypogynous. Stamens 5, opposite the petals, and adhering to them at the base. Style 3-cleft or 3-furrowed.

Culture and Propagation.—Claytonias are adapted for the rockery or

wild garden. The annual fibrous-rooted species may be increased by seeds; the tuberous-rooted ones also by seeds, or by offsets taken in autumn or spring. The tuberous species thrive best in damp peaty soil; the annuals in loamy soil.

C. caroliniana. — A spreading dwarf species, native of North America, with spatulate oblong or ovate-lance-shaped leaves. Flowers in spring, rosy, in loose racemes.

Culture &c. This species may be grown in peaty soil in the rock garden in partially shaded and moist situations. It may be increased by seeds sown as soon as ripe in pots or pans in cold frames. The seedlings are pricked out and grown on till the following spring before transferring to the open ground. The roots may also be divided in early autumn or in spring.

C. perfoliata. — An annual species 3-6 in. high, native of N.W. America to Mexico, and Cuba, also found naturalised in parts of the British Islands. Upper leaves connate or perfoliate, forming a roundish disc; lower ones stalked, oval-rhomboid. Flowers from May to August, white, small.

Culture &c. This species will grow in any garden soil, and may be increased by seeds sown out of doors as soon as ripe, or in April and May.

C. sibirica. — A Siberian perennial 3-6 in. high, with spindle-shaped roots. Leaves ovate, the lower ones stalked, upper ones opposite, sessile. Flowers in spring, rosy, with 2-cleft petals.

Culture &c. as above for *C. caroliniana*.

C. virginica. — A tuberous-rooted N. American perennial 3 in. high. Leaves linear lance-shaped. Flowers in spring, white, with notched petals.

Culture &c. as above for *C. caroliniana*.

SPRAGUEA. — A genus containing only one species here described:—

S. umbellata. — A rare Californian perennial 6-9 in. high, with somewhat fleshy spatulate leaves, and small scarious stipules. Flowers in summer, pinky-rose, in dense imbricated spikes. Sepals 2, roundish heart-shaped, membranaceous, persistent. Petals 4, hypogynous. Stamens 3, opposite the petals,

and adhering to them at the base. Style 2-cleft.

Culture and Propagation. — This species is probably not quite hardy in unfavourable parts of the country, and in such places may require slight protection. It grows in ordinary soil and is useful for the rockery, or edges of the flower border. To obtain flowers the same year, seeds should be sown on a hotbed in February, the seedlings being pricked out singly into small pots so as to be ready for planting out by the end of May, to bloom in August and September. Seeds sown later in the open will not produce flowers until the following spring or summer.

LEWISIA. — Like the preceding, this genus has only one species:—

L. rediviva (*Spatulum*). — A remarkable and pretty N. American plant 1-3 in. high, with edible, tapering, fleshy, red-stemmed roots, white within. Leaves densely tufted, linear, fleshy, withering on the appearance of the flowers. The latter appear in summer on one-flowered scapes, jointed above the middle, pink, with a nearly white centre, 3-4 in. across. Sepals 6-8 (most of the other plants in this order have only 2), broadly ovate, contorted, imbricate, finely veined with red, persistent. Petals 8-10, hypogynous, imbricate. Stamens numerous, inserted with the petals. Styles deeply 6-8-cleft.

Culture and Propagation. — This species should be planted in a nook or crevice in the rockery, where its fleshy roots will obtain plenty of moisture. The position, however, should be a sunny one, as the flowers will not readily develop in shady spots. After blooming the plant shrivels up into a withered string-like mass. In very hot seasons the plants should be watered every day. *Lewisias* are increased by seeds, or by dividing the roots in spring. The seeds should be sown as soon as ripe in pots or pans in cold frames, and the seedlings after being pricked out should be grown on during the winter months in the frames until fine weather in spring, when they may be planted out. Or the seeds may be sown in gentle bottom heat about February and March. The seedlings are pricked out and hardened off so as to be ready for the open air by the end of May or beginning of June.

XXI. TAMARISCINÆ—Tamarisk Order

A small genus containing 5 genera, and about 40 species of shrubs or undershrubs, rarely trees or durable herbs. Leaves alternate, very small, often scale-like, imbricate, entire, and often fleshy with a usually pitted surface. Stipules none. Flowers regular, often hermaphrodite, in close spikes, or racemes, often white or rose, flesh-coloured, small or showy. Sepals 5, rarely 4, free or connate at the base, much imbricated in bud. Petals 5, rarely 4, free, or cohering in a tube at the base. Disc hypogynous or slightly perigynous, 10-glandular, crenate or angulate, rarely absent. Stamens 5 or more, inserted on the disc, free, or variously connate at the base. Anthers 2-celled, versatile. Ovary free, 1-celled, or imperfectly septate. Capsule dehiscent, leathery.

TAMARIX (TAMARISK).—A genus containing about 20 species (50 according to some authors) of small trees or bushes, with minute, scale-like leaves, stem-clasping or sheathing. Flowers white or rose, in spikes or dense racemes. Sepals 4-5, rarely 6, free. Petals 4-5, inserted under the glandular, crenate, angled or lobed disc, free, or slightly connate at the base. Stamens 5-10, rarely 4, or 11-12, inserted on the disc, free or connate in a ring near the base. Ovary narrowed upwards; styles 3-4, short, thick.

Culture and Propagation.—The Tamarisks thrive in almost any good garden soil, and are very effective ornaments in shrubberies and borders. Along the south coast and in the Channel Islands the common Tamarisk (*T. gallica*) is a lovely feathery, Heath-like tree. Plants may be increased by inserting cuttings of the flowerless shoots about 4 in. long under glass in sandy soil during the summer months. When well rooted they may be planted out in spring in a warm sunny border and well watered.

Seeds may also be sown as soon as ripe in cold frames, and the young plants may be grown in the frames until the following spring, when they may be transferred to a warm and sheltered border. Seeds may also be sown in spring and treated in the same way.

T. chinensis.—This is somewhat similar to *T. gallica*, but has if anything a more graceful and feathery appearance. It is sometimes called *T. japonica plumosa*, and produces pink flowers.

Culture &c. as above. It is not quite so hardy as *T. gallica*.

T. gallica (*Common Tamarisk*).—A fast-growing, beautiful evergreen shrub 6-12 ft. high, native of Britain, and also distributed throughout Europe to India. Leaves very small, closely imbricated, triangular, auricled and keeled on the very slender, feathery branchlets, and about $\frac{1}{2}$ in. long, and awl-shaped on older wood. Flowers from July to September, white or pink, in catkin-like spikes 1 in. long.

Culture &c. as above.

T. hispida (*T. khasgarica*).—This is a recently introduced species from Central Asia. The leaves are very small and blue-green in appearance, closely pressed to the stems, and the rosy-carmine flowers are produced in autumn.

Culture &c. as above.

T. parviflora (*T. africana*).—A native of S.E. Europe, 6-10 ft. high, with small lance-shaped acute leaves, slightly keeled. Flowers in summer, pink, crowded on spikes or lateral racemes.

Culture &c. as above.

T. tetrandra.—A Caucasian shrub 6-8 ft. high, with lance-shaped stem-clasping leaves. Flowers in summer, pinkish-white, borne on lateral racemes about $1\frac{1}{2}$ in. long, and remarkable for having only 4 stamens or anthers, as indicated by the name.

Culture &c. as above. This species is very hardy and produces seeds freely in the neighbourhood of London.

MYRICARIA.—A small genus containing 3 or 4 closely related species of deciduous undershrubs, with small,

narrow, clustered leaves. Flowers rosy or white, in long spiked terminal racemes, leafy at the base. Sepals and petals 5, free. Stamens usually 10, inserted on the disc, slightly connate at the base or beyond the middle.

M. germanica.—An elegant Heath-like shrub 3-6 ft. high, native of Europe and Asia, with rigid, erect, and slightly angular branches. Leaves somewhat glaucous, linear, blunt, spotted. Flowers in summer, white or rose-tinted, in spike-like racemes; petals lance-shaped, acute.

Culture and Propagation.—The above is the only species of note. It is a good shrub for dry banks in warm sandy soils, and may be increased by seeds sown in the open air about May, or by cuttings of the firm young wood during the summer months, inserted in light sandy soil under a handlight. They may be transplanted in mild weather the following spring.

REAUMURIA.—A genus of 10 species of little-known much-branched

procumbent or straggling shrubs with small or roundish, fleshy, often clustered leaves. Flowers terminal, solitary, often showy, larger than in *Tamarix*. Sepals 5, nearly connate at the base or almost free, surrounded by few or many imbricated sepaloïd bracts. Claws of the petals broad. Stamens numerous, free, or in 5 bundles opposite the petals, more or less connate at the base. Styles 5, awl-like.

R. hypericoides.—A beautiful Syrian shrub about 2 ft. high, with leathery leaves, varying from linear to lanceolate oblong. Flowers in summer, purple; petals irregular, ovate or ovate-oblong, very blunt, with appendices short and slightly fimbriate at the apex.

Culture and Propagation.—This species grows readily in sandy loam and peat in a warm corner of the border or shrubbery. Cuttings of the ripe young wood root readily in a sandy soil under a bell glass in the same way as recommended for *Tamarix* and *Myricaria*.

XXII. HYPERICINEÆ—St. John's Wort Order

An order containing 8 genera and over 200 species of evergreen or deciduous herbs, shrubs, or rarely trees. Leaves opposite, rarely verticillate, simple, entire, penni-nerved, or glandular-toothed, herbaceous, or very rarely leathery in texture, sometimes small or needle-like, usually full of pellucid dots, and bordered with black glands. Stipules none. Flowers regular, hermaphrodite, terminal or rarely axillary, solitary, cymose or cymose paniculate, usually yellow or white. Sepals 5, rarely 4, imbricate. Petals 5, rarely 4, hypogynous, imbricate, often contorted, bordered with blackish dots, sometimes with a fleshy scale or hollow at the base. Stamens numerous, hypogynous, often in 3 or 5 connate or approaching bundles, sometimes in many bundles, with fleshy glands intervening.

HYPERICUM (ST. JOHN'S WORT). A genus containing about 160 species of deciduous or evergreen shrubs or under-shrubs. Leaves often almost sessile, small or membranaceous, entire or rarely somewhat toothed, usually with pellucid black dots at the edges. Flowers yellow, rarely white, solitary, cymose or paniculate. Sepals and petals 5. Stamens free or slightly cohering at the base into 3-8 bundles. Styles distinct or rarely cohering.

Culture and Propagation.—Hypericums prefer a rich sandy loam, but will grow readily in any ordinary garden soil.

They are useful for shrubberies, borders, banks, or in beds by themselves. They are increased quickly from seeds or cuttings, or by dividing the creeping rooted species. The half-hardy kinds may require a little protection in winter in northern parts of the country. All the kinds described below lose their leaves in winter and have yellow flowers except where otherwise stated.

H. ægyptiacum.—A half-hardy round-stemmed evergreen 6-18 in. high, native of N. Africa and the Levant. Leaves glaucous, small, ovate, crowded, without

dots. Flowers in summer, small, few, almost sessile.

Culture and Propagation.—Although from sunny Mediterranean climes this species is hardy in ordinary winters in the neighbourhood of London. It must, however, be grown in warm and sheltered spots and in well-drained rather sandy soil. Cuttings of the ripened or half-ripened shoots, without flower buds, may be rooted under a handlight during the summer and autumn months, and transplanted the following spring. Seeds may also be sown as soon as ripe, if obtainable, and the young plants moved into a warm border the following spring after all danger from frost is over.

H. Androsæmum (*Sweet Amber; Common Tutsan*).—A sub-shrubby species, native of Britain, with sessile, ovate, somewhat heart-shaped leaves, minutely dotted. Flowers in summer, large, terminal, stalked.

Culture &c. as above. Seeds freely produced.

H. Ascyron.—A Siberian species 3 ft. high, with 4-angled stems. Leaves stem-clasping, lance-shaped, acute, full of pellucid dots. Flowers in summer, very large.

Culture &c. as above. Seeds freely produced.

H. calycinum (*Aaron's Beard; Rose of Sharon*).—A beautiful almost evergreen species about 1 ft. high, with 4-angled stems, native of S.E. Europe, and naturalised in parts of Britain. Leaves broadly ovate, lance-shaped, leathery, full of pellucid dots. Flowers in summer, large, terminal, solitary, 3 in. across.

Culture &c. as above. Seeds freely.

H. Coris.—A half-hardy round-stemmed evergreen 6–24 in. high, native of the Levant. Leaves in whorls, linear, with revolute edges. Flowers from May to September, less than 1 in. across.

Culture &c. as above, p. 265.

H. elatum.—A N. American species about 5 ft. high, having reddish stems when young. Leaves ovate-oblong acute, dilated at the base, slightly notched and rather revolute at the edges. Flowers in July, borne in corymbose clusters.

Culture &c. as above. Seeds produced freely.

H. elegans.—A fine Siberian plant 1 ft. high, with winged and black-dotted stems. Leaves ovate-lance-shaped, some-

what stem-clasping, bluntnish, full of pellucid dots. Flowers in summer, borne in racemose clusters.

Culture &c. as above. This species seems to be somewhat rare.

H. elodes.—A native of bogs, ditches and wet moors in the British Islands, with creeping, round, hairy stems. Leaves roundish, ovate blunt, shaggy, woolly, full of pellucid dots. Flowers in summer, $\frac{1}{2}$ in. across, pale yellow with green ribs, opening only in sunshine. Sepals smooth, oblong blunt, with red glandular serratures.

Culture &c. as above. A good plant for the bog garden.

H. empetrifolium.—A half-hardy evergreen 6–12 in. high, native of South Europe, with slender erect 4-angled branchlets. Leaves linear with revolute margins. Flowers in summer; petals without glands.

Culture &c. as above, p. 265.

H. hircinum (*Goat-scented St. John's Wort*).—A species from the Mediterranean region, 2–4 ft. high, with winged branches. Leaves dilated, sessile, ovate-lance-shaped, with glandular edges. Flowers in summer, large, with very long styles.

There is a variety called *minor* which is smaller in all its parts.

Culture &c. as above. Seeds freely produced.

H. hookerianum (*H. oblongifolium*).—A half-hardy evergreen 2 ft. high, native of Nepal, with round, shrubby stems. Leaves elliptic-lance-shaped, crowded, slightly revolute at the edges, full of pellucid dots. Flowers in summer, large.

Culture &c. as above. Seeds freely produced.

H. japonicum.—A Japanese species about 1 ft. high, with weak, 4-angled, smooth, decumbent stems. Leaves broadly ovate, mucronate, blunt, with revolute edges, full of pellucid dots. Flowers in spring, small, in loose panicles.

Culture &c. as above.

H. kalmianum.—A North American species 2–4 ft. high, with 4-angled stems, and linear lance-shaped leaves. Flowers in summer, 3–7 in a terminal corymb-like cluster.

Culture &c. as above. Seeds freely.

H. moserianum.—This is a hybrid between *H. calycinum* and *H. patulum*,

and has become very popular of late years. There is a beautiful variegated form called *tricolor*, the leaves of which are blotched with white, green, and rosy-carmine.

Culture &c. as above, p. 265.

H. nummularium.—A Pyrenean species 3–6 in. high, with round ascending stems, and roundish stalked leaves. Flowers in summer, racemose.

Culture &c. as above, p. 265.

H. orientale.—A native of the Levant, 6–12 in. high, with erect, slender, 2-angled stems. Leaves stem-clasping, linear, blunt, erect, fringed with glandular hairs. Flowers in summer.

Culture &c. as above, p. 265.

H. patulum.—A Japanese species 6 ft. high, with round, purplish, herbaceous stems. Leaves ovate lance-shaped, acute, tapering to the base, revolute at the edges, without dots.

Culture &c. as above. Seeds freely produced.

H. perforatum (*Common St. John's Wort*).—A native of the copses and hedge-banks in the British Islands, and also distributed in the north temperate regions. It grows about 3 ft. high and has slender brown stems. Leaves sessile, oblong, with pellucid dots and occasionally a few black ones beneath. Flowers from July to September, 1 in. across; sepals

lance-shaped acute, entire, with a few glandular lines or dots.

Culture &c. as above. Seeds freely produced.

H. prolificum.—A round-stemmed species with angular branches, 1–2 ft. high, native of N. America. Leaves linear lance-shaped, with revolute edges, full of pellucid dots. Flowers in summer, corymbose. *H. densiflorum* is closely related, but has narrower leaves and smaller flowers.

Culture &c. as above. Seeds freely produced.

H. pyramidatum.—A N. American species 4 ft. high, with winged herbaceous stems. Leaves stem-clasping, oblong-lance-shaped, acute, with revolute edges. Flowers in summer, large, on short thick stalks.

Culture &c. as above, p. 265.

H. triflorum.—A half-hardy smooth-stemmed species, native of the mountains of Java. Leaves membranous, ovate-oblong, bluntish, full of pellucid dots. Flowers in summer, solitary, usually in threes on terminal stalks.

Culture &c. as above, p. 265.

H. uralum.—A native of Nepaul 2 ft. high, with 2-edged compressed branches. Leaves elliptic, abruptly pointed, smooth, shining. Flowers in summer, terminal, somewhat corymbose.

Culture &c. as above, p. 265.

XXIII. TERNSTRÆMIACEÆ—Camellia Order

An order containing over 30 genera and 260 species of trees and shrubs, rarely climbers. Leaves alternate, rarely opposite, simple and entire or rarely digitately 3–5-lobed, or often serrate, leathery, penni-nerved. Stipules none, or very rarely, minute, and very caducous. Flowers regular, hermaphrodite, or rarely diclinous. Sepals 5, rarely 4, or 6–7, free, or slightly cohering at the base, imbricate, the inner ones often larger. Petals 5, rarely 4, or 6–9, hypogynous, free or often cohering in a short tube or ring at the base, much imbricated or twisted. Stamens usually numerous, rarely equal in number to the petals, hypogynous, free or often connate with each other at the base, or adnate to the base of the corolla. Disc none. Ovary free. Peduncles 1- or many-flowered; or flowers in terminal or axillary racemes, rarely in elongated panicles, often with 2 bracteoles beneath the calyx.

ACTINIDIA.—A genus containing about 8 species of ornamental, climbing, smooth, stiffly hairy or woolly shrubs,

with entire or serrate leaves often membranaceous, penni-nerved. Flowers polygamous or diceious. Sepals 5, slightly

imbricate, somewhat connate at the base. Petals 5, rather twisted, imbricate. Stamens numerous, with versatile anthers.

Culture and Propagation.—Actinidias thrive in a light, rich, loamy soil in warm situations, and are excellent for trailing over walls, trellises, arbours &c. They may be increased by seeds sown in gentle heat under glass, or the shoots may be layered during the summer and autumn months. Cuttings of the ripened shoots may also be rooted in the autumn in sandy soil under a bell glass and grown on during the winter months under the protection of a cold frame or greenhouse.

A. Kolomikta.—A beautiful species from N.E. Asia, with ovate-oblong, stalked serrate leaves, rounded or somewhat cordate at the base, and tapering to a long point, very beautiful in autumn, changing to red and white. Flowers in summer, white, $\frac{1}{2}$ in. across, solitary, axillary or cymose, the stalks being covered with fluffy white down.

Culture &c. as above.

A. polygama.—A Japanese species, with heart-shaped, serrate, reddish-stalked leaves about 3 in. long, and fragrant white flowers in June and July, drooping from the leaf axils and succeeded by edible berries in the autumn months.

Culture &c. as above.

A. volubilis.—A free-growing Japanese climber, with oval and elliptic leaves, and small white flowers in June.

Culture &c. as above.

STACHYURUS.—A genus containing only 2 species of smooth shrubs or small trees with membranous serrate leaves and small flowers in lateral spikes or racemes. Sepals and petals 4 each. Stamens 8, free. Fruit a 4-celled berry.

S. præcox.—A Chinese and Japanese shrub with flexible stems 9-10 ft. high, furnished with bright more or less oval-lance-shaped tapering leaves 4-6 in. long, with serrulate edges. The small greenish-yellow flowers are freely borne in short axillary clusters early in March, before the leaves are developed.

Culture and Propagation.—This plant flourishes in ordinary good and well-drained garden soil, and may be utilised like the Actinidias for clothing a south wall which will give it the necessary protection from cold winds. It may be easily increased by cuttings of the ripened

or half-ripened shoots in August and September, placed in sandy soil under a handlight and protected until the following spring from the severities of winter.

STUARTIA.—A genus containing 3 species of beautiful shrubs, with membranous deciduous leaves, and shortly stalked, solitary, axillary flowers. Sepals and petals 5, rarely 6, the latter imbricate, cohering at the base. Stamens numerous, adhering to the base of the petals; anthers versatile. Styles 5, distinct, or connate.

Culture and Propagation.—Stuartias thrive in a peaty and loamy soil, and in the milder parts of the country make handsome shrubs. In less favoured parts they should be protected from the north and east winds by hardier trees and shrubs, as the young shoots are apt to be injured by severe frosts. A warm and sunny position is essential for the thorough ripening of the growths.

The plants may be increased by layering the lower branches, or by putting cuttings of ripened wood in sandy soil under a bell glass during the late summer and autumn months.

S. pentagyna (*Malachodendron ovatum*).—A somewhat slow-growing species about 10 ft. high, native of N. America, with ovate-acute leaves. Flowers from May to July, creamy-white, with 5-6 sepals and petals, the latter being obovate with jagged edges and a purplish downy outer surface.

Culture &c. as above.

S. pseudo-camellia (*S. grandiflora*). A beautiful Japanese shrub, about 12 feet high. Leaves ovate-elliptic, shortly toothed, pointed, narrowed into a reddish stalk. Flowers in summer, creamy-white, with finely serrulate dull reddish-brown sepals.

Culture &c. as above.

S. virginica.—A rounded and spreading bush 6-10 ft. high, native of N. America, with oblong-ovate, serrulate leaves, softly downy beneath. Flowers in early summer, white, about 3 in. across, with crimson-red stamens. Sepals ovate; petals 5, roundish-obovate.

Culture &c. as above.

GORDONIA (LOBLOLLY BAY).—A genus containing 10 species of evergreen trees or shrubs with entire or crenate leaves. Peduncles solitary, 1-flowered.

Sepals usually 5, unequal. Petals free, or slightly connate at the base, much imbricated, the inner ones larger. Stamens numerous, often in 5 bundles, or united in a ring and adnate to the petals.

Culture and Propagation.—The species mentioned below are the only ones grown out of doors in the British Islands, and, although they have been introduced more than a century and a half, are still very little known. This is owing chiefly to the fact that they are not readily increased, either by seeds or layers—the methods of propagation usually adopted. They thrive in light peaty soil with plenty of leaf mould in it, and should be placed in the most sheltered and warmest parts of the garden.

As seeds are very rarely produced in our climate, it is not possible to obtain plants by that means very often. Imported seeds should be sown immediately on arrival, in light sandy peat and leaf soil, and placed in gentle heat. Layers may be made during the summer and autumn months, and cuttings of the ripened shoots may also be inserted in moist sandy peat and loam, either in gentle heat (which is best) or under a handlight.

G. Lasianthus.—A beautiful Camellia-like shrub 8–10 ft. high, native of the sea-coast swamps of the S. United States. Leaves oblong, smooth, serrated, leathery. Flowers from July to September, white, about 4 in. across, fragrant, borne in the axils of the leaves.

Culture &c. as above.

G. pubescens.—A slightly dwarfed species from the same region, with obovate-lance-shaped, somewhat serrated leaves, downy beneath. Flowers late in summer, white, about 3 in. across, fragrant, with a bundle of conspicuous golden-yellow stamens in the centre.

Culture &c. as above.

CAMELLIA.—A genus which includes over a dozen species of beautiful evergreen trees and shrubs, with serrated, leathery or membranous shining green leaves. Flowers axillary, solitary or clustered, sessile or shortly stalked, showy. Sepals 5–6, unequal, gradually passing from bracteoles to petals; the latter slightly cohering at the base, much imbricated. Stamens numerous, many of

the outer ones cohering and attached to the base of the petals; inner ones free.

Camellias, although usually grown in cool greenhouses, are in reality hardier plants than is generally supposed. From the Thames Valley southwards, and in favourable parts of the south-west of Scotland and Ireland, they are practically hardy. Indeed during the severe frosts of the winters of 1879–80 and 1880–81 Camellias in widely distant parts of the country (Wales, Isle of Wight, Dorset, Argyllshire, Surrey, Cornwall &c.) were quite uninjured by frosts, although in many parts well-favoured geographically the plants were injured. Altitude, exposure, soil and drainage would account for this, however, in many cases.

Culture and Propagation.—Camellias like a good rich compost of sandy peat and loam, and should never be allowed to get too dry at the roots, as the flowers are likely to drop as a consequence. The plants are greatly benefited by a daily syringe during the summer time—either early in the morning or late in the afternoon. If the water is applied with some force from a hose pipe, the stems and leaves are kept beautifully clean, and the flower buds become plumper, and are more likely to develop, than if the plants are not attended to.

The best position for the Camellia is facing north or north-west, with a wall or hedge in the background for protection from fierce cold winds, which seem to do a good deal of mischief. If low-growing hardy shrubs like *Osmanthus*, *Olearia* &c. are planted in front of them, they are a great protection to the stems and roots, which are often more affected by biting winds than the foliage. A shady position, but one at the same time fully exposed and well ventilated, is best for outdoor Camellias, as they do not like the scorching heat and bright sunshine of summer.

As the wood is fairly well-ripened by July, that is the best time for planting—either from pots or the open ground. Have the hole sufficiently large to admit of the roots being evenly spread over the surface and not crumpled up in a ball. In this way the soil will get in among the roots properly, new ones will develop more rapidly, and thus enable the plants to become well established before the winter. Planting is always best done in dull showery weather, so that the plants will not suffer too much by the evaporation

of moisture from the foliage. If planting takes place in dry sunny weather, the soil should be well watered and the plants should also be well syringed daily, early in the morning and late in the afternoon, and until they are well established it may be advisable to shade them during the hottest portion of the day with a covering of thin canvas or some other light material. The way to plants trees properly is shown in the diagram at p. 1032.

Single-flowered Camellias may be increased by seeds, layers, or cuttings, the two latter methods being used for the double and variegated kinds. Cuttings are best taken in August, and inserted in sandy peat and loam in a cold shaded frame. By the following spring those that have rooted will begin to grow. They should then be potted off singly in a similar compost and kept in a close frame for a time and well syringed until well established, when they may have plenty of air to ripen the wood. Camellias are also grafted or 'inarched' in early spring when growth begins upon stocks of the common variety of *C. japonica* which are raised from cuttings. Without the aid of a greenhouse, however, it is not worth while for the amateur to raise his own plants. He will get them much better and cheaper from a nurseryman.

Most of the Camellias seen in gardens are varieties of *C. japonica*, but other species also are here described.

C. euryoides.—A hairy, branched Chinese species, about 4 ft. high, with ovate lance-shaped, pointed leaves, serrated on the edges, and silky beneath. Flowers from May to July, white.

Culture &c. as above. This plant is very rarely seen.

C. japonica.—A lovely tree about 20 ft. high, native of Japan and China, with ovate, pointed, sharply serrated leaves. In a wild state the flowers are red, resembling those of the Wild Rose.

This species was introduced to Europe in 1739 by Lord Petre, but the double-flowered forms did not appear until 1792 onwards. The variety *anemoneiflora* has nearly all the stamens transformed into small incurved petals, which give the flower a likeness to a double Anemone.

Among the many varieties of *C. japonica*, the following are probably best for outdoor culture, but others may be equally good, if not better:—

alba plena, double white; *Chandleri elegans*, large, light rose; *Donckelaari*, large semi-double, rich crimson, marbled white; *fimbriata alba*, white petals notched at edges; *imbricata*, deep carmine, occasionally variegated; *Lady Hume's Blush*, very free, good form, flesh colour; *Mathotiana*, brilliant red, and *Mathotiana alba*, white; *Lavinia Maggi*, pure white, flamed with cerise; *Countess of Orkney*, white, striped with carmine, sometimes pink, shaded with deep rose.

Culture &c. as above.

C. reticulata.—A fine Chinese shrub about 10 ft. high, with oblong pointed, serrated, net-veined leaves, and large semi-double bright rose flowers. There is also a full double-flowered form, and it is possible that many of the garden forms are derived from this species.

Culture &c. as above. This species must be grown in warm, sheltered, and sunny situations as it does not like exposure to cold winds.

XXIV. MALVACEÆ—Mallow Order

An extensive order (about 60 genera and 700 species) of herbs, shrubs, or rarely trees, with stellate hairs. Leaves alternate, usually palm-nerved, more or less divided, stipulate. Peduncles axillary and one-flowered, in fascicled racemes or panicles. Flowers regular, hermaphrodite, rarely dicæcious or polygamous. Sepals 5, rarely 3-4, more or less united at the base. Petals 5, hypogynous, twisted in bud, free, or adhering to the base of the stamen tube. Stamens many, hypogynous, filaments more or less united, rarely free. Disc small, sometimes growing up between the numerous carpels. Fruit dry

or rarely berry-like, the carpels often united and forming a fruit known as a *carcerule* (see Glossary, fig. 27).

MALOPE.—A genus containing only 3 species of little-known smooth or hairy ornamental annuals, with entire or 3-cleft leaves. Flowers stalked, violet or rose, with 3 large heart-shaped bracteoles. Calyx 5-lobed, persistent. Stamen-tube divided into numerous filaments.

Culture and Propagation.—Malopes thrive best in sandy loam, in sunny situations, but are not fastidious. They may be raised from seeds sown in slight heat in March, or in the open border at the end of April. The latter method is better on the whole, as the seedlings do not stand transplanting from seed pots very well. When sown in the open border they may simply be thinned out 6-9 in. apart. During the summer months they require to be frequently watered as they absorb and exhale moisture very freely. They look more effective in masses or groups.

M. malacoides.—A native of South Europe, about 1 ft. high, with oblong-ovate, crenate or pinnatifid leaves, wedge- or heart-shaped at the base. Flowers in summer, large, rose-pink, tinged with purple.

Culture &c. as above.

M. trifida.—A beautiful annual 1-3 ft. high, native of S. Spain. Leaves 3-cleft, toothed, smooth, with pointed lobes. Flowers from July to September, large, solitary, purple, or white as in the variety *alba*. The variety *grandiflora* is a well-known and more vigorous plant with crimson flowers, of which there are red and white variations.

KITAIBELIA.—A genus with only one species here described:—

K. vitifolia.—A perennial herb 6-8 ft. high, native of E. Europe. Leaves Vine-like, 5-lobed, acute, toothed. Flowers late in summer, stalked in the axils of the upper leaves, large, showy, white or rose. Calyx 5-lobed, with 6-9 united bracts. Stamen-tube divided into numerous filaments.

Culture and Propagation.—This species thrives in any garden soil and is easily increased by dividing the rootstock after flowering. Seeds are produced freely and may be sown as soon as ripe in cold frames or in gentle heat in greenhouses. The seedlings should be pricked out into

boxes or pans, or into fine sandy soil in cold frames, giving them protection from frost until the following spring, when they may be transferred to the open border. The seeds may also be sown either in gentle heat early in spring or in the open ground during April and May.

PALAVA.—A small genus containing only 3 species of rather smooth or woolly annual herbs, natives of Chili and Peru, with leaves often lobed, sinuate, or dissected. Flowers stalked, axillary, solitary, purple. Calyx 5-cleft. Stamen-tube divided into numerous filaments.

Culture and Propagation.—Palavas thrive in ordinary soil. Seeds may be sown in a little heat in March, so that the seedlings will be ready for transplanting by the end of May. Or seeds may be sown in the open border in April, afterwards thinning the seedlings out 6-9 in. apart.

P. flexuosa.—A pretty slender-stemmed annual about 1 ft. high, with twice pinnatifid, hairy, stalked leaves 2-4 in. long. Flowers in summer, light mauve or lilac, paler in the centre, with bright red anthers; petals red and sepals purple at the base. This species is also known as *Pakava dissecta*. It seeds freely in the British Islands, and in warm favourable localities would probably reproduce itself annually from self-sown seeds.

Culture &c. as above.

P. rhombifolia.—A somewhat prostrate hairy species with soft rhomboid leaves, about 2 in. long. Flowers in July and August, rose-purple, about 1 in. across, scentless.

Culture &c. as above.

ALTHÆA.—This genus contains about a dozen species of more or less well-known tall or dwarf woolly or hairy biennials or perennials with lobed leaves, and usually solitary, axillary or racemose flowers variously coloured. Bracteoles of the involucre or outer calyx 6-9-cleft, united at the base. Calyx 5-cleft. Stamen-tube divided into numerous filaments. Carpels in a regular whorl, 1-seeded, indehiscent.

Culture and Propagation.—Most of the plants thrive in almost any garden

soil, and being of somewhat coarse and vigorous growth are suitable for shrubberies or the rougher parts of the flower garden. The perennial species may be increased in early autumn or in spring by dividing the rootstocks carefully. They may also be multiplied by sowing the seeds as soon as ripe either in a warm border or in a cold frame, afterwards thinning the seedlings out, or pricking them out into light rich soil at least before the end of September. The cultivation of the Hollyhock will be dealt with separately under the species from which it has been derived, viz. *A. rosea*, and as a matter of fact the other species described may be cultivated in the same way.

A. cannabina.—A perennial 5-6 ft. high, native of S. France. Leaves downy, lower ones palmately parted, upper ones 3-parted, lobes narrow, teeth coarse. Flowers in summer, rose.

Culture &c. as above. Increased by seeds or division.

A. caribæa.—A hairy-stemmed biennial about 3 ft. high, native of the Caribbee Islands. Leaves heart-shaped, roundish, lobed, crenate-serrate. Flowers in spring, rosy, with a yellow base.

Culture &c. as above and for *A. rosea* below.

A. ficifolia (*Antwerp Hollyhock*).—A stout and vigorous Siberian biennial 6-10 ft. high, with somewhat open hand-shaped leaves, irregularly toothed on the edges. Flowers in summer, red or yellow or orange, large, single or double.

Culture &c. as above and for *A. rosea* below.

A. flexuosa.—A perennial 2-3 ft. high, native of N. India, with long-stalked, cordate, 7-lobed leaves. Flowers in summer, scarlet, solitary; petals obcordate.

Culture &c. as above and for *A. rosea* below.

A. narbonensis.—A strong-growing perennial 3-6 ft. high, native of France and Spain. Leaves downy, serrated, lower ones 5-7-lobed. Flowers in August, pale red, on many-flowered stalks.

Culture &c. as above and for *A. rosea* below. This plant is closely related to *A. cannabina*, and is practically a botani-

cal form of it, although distinct enough for garden purposes.

A. officinalis (*Common Marsh Mallow; Guimauve*).—A well-known British marsh plant 3-4 ft. high, with soft, woolly, heart-shaped or ovate, toothed, undivided, or slightly 5-lobed leaves, and flowers in summer of a delicate bluish colour.

Culture &c. as above. This species is useful for associating with bog or marsh plants, and therefore requires to be grown in moister soil than the other species.

A. rosea (*Hollyhock*).—The wild Hollyhock is a straight-stemmed, hairy perennial 6-10 ft. or more high, native of China. Leaves rough, heart-shaped, with 5-7 crenated angles or lobes. Flowers in summer, rosy, large, axillary, without stalks, somewhat spiked at the top.

The cultivated Hollyhock, which has been derived in almost innumerable varieties from this species, and has been grown for more than 300 years, is one of the most beautiful and noble-looking of hardy plants. From 35 to 40 years ago it was extensively cultivated, and from July to the end of September was a feature at horticultural exhibitions. There were the English and Scottish types, the former having small closely set flowers, with neat, well-filled centres and narrow 'guard-petals'; the latter large flowers, wide guard-petals, and smaller centres indented with openings called 'pockets.' The two types were crossed with each other, and a new race—that now most generally seen—was the result.

Soil.—Hollyhocks like a deep, rich, loamy soil, well enriched with farmyard manure. About the end of March is the best time for planting, the ground having previously been well trenched or dug. During the hot summer months the plants should have plenty of water. A mulching of well-rotted manure will greatly assist in keeping the moisture in the soil, and prevent its being baked by the fierce rays of the sun. Plenty of moisture at the root in summer and dryness in winter suit Hollyhocks best.

Propagation.—Hollyhocks may be increased by seeds, cuttings, or by carefully dividing the rootstock; also by 'eyes,' that is buds, taken with a portion of the older stem, usually during July and August. By seed is probably the easiest and most natural method, and there is

always a chance of obtaining some really fine varieties, whereas the other methods simply reproduce their parents. Seeds have the further advantage of requiring no glass protection; and on the whole plants obtained by this means are not nearly so liable to attacks of the dreaded Hollyhock disease as plants raised from cuttings that have been rooted in heat. The seeds may be sown in the open border in May, and the seedlings may be afterwards pricked out about 6 in. apart in a prepared bed of fine soil. About the first or second week in September they may be transplanted to the spot in which they are to bloom the following year, and there should be at least 3 ft. between the plants in the beds or borders. If planted too close to each other, a good circulation of air is prevented, and this in itself is favourable to the development of the Hollyhock disease mentioned below.

Cuttings are taken in the summer and autumn by cutting out the matured side shoots, or from shoots at the base of the stem. They may be inserted in sandy soil either singly in small pots, or several in a shallow box or pan, and placed at first in a close shaded frame, a little air being given after a few days. As the plants become well rooted and established, they should receive all the air and light possible so that they may never be subject to a damp and sluggish atmosphere.

General Remarks.—Although vigorous Hollyhocks will shoot their strong stems up to a height of 8 to 12 ft. they are liable if at all exposed to strong winds to be blown about, and more or less spoiled. It is advisable therefore to supply stoutish stakes 4-6 ft. high at the time of planting, so as to prevent injury to the roots at a later period. As the stems lengthen they may be tied to the stakes with a piece of raffia or tar twine. The tie should first of all be made firmly round the stake at the desired height so that it will not slip up and down. The loop of the tie may then be left large enough for the stem, but not so tight as to cut into the bark.

As the lower flowers, which open first, begin to fade, the petals only should be removed if seeds are required, leaving the pods to ripen; but if not, the pod and all may be removed for the sake of a tidy appearance. The spikes themselves, if cut and placed in water, will retain their freshness for a considerable time and the flowers will continue to open. By fre-

quently cutting a piece off the bottom of the stem the blossoms last longer.

When the flowers, seed-pods, and leaves have finished their season's work, the plants may be cut down to within 6 in. of the ground, and the soil may be raised a little around the crowns to throw off the cold rains of winter, which are injurious if not drained away from the roots. In this protected state the root-stocks pass through severe winters safely, and make vigorous shoots the following spring. Treated in this way plants will continue to flower profusely for several years without being disturbed, but it is always safe to raise a stock of young plants regularly by one or other of the methods described above.

Insect Pests.—In hot weather red-spider is apt to be very troublesome to the foliage, if the plants have not been frequently syringed. A daily application of water to the leaves, and particularly the under surface, will keep this pest away, and also serve to water the plants. Thrips are also fond of the Hollyhock, but may be checked by the same means. In the early stages of growth the spittle-fly is somewhat mischievous, but is easily destroyed between the finger and thumb.

The Hollyhock Fungus (*Puccinia malvacearum*) is by far the most serious disease the gardener has to cope with. It is a native of Chili, whence it was introduced to Europe about 1869, and in 4 or 5 years had spread with great rapidity, dealing destruction all round to Hollyhocks in England, France, Germany, Holland, Hungary and parts of Italy.

The fungus appears in early summer in yellow or orange spots on the leaves—usually the under surface—and stems of the Hollyhock. The spots rapidly increase in size, becoming brown in colour, and when in great profusion interfere with the work of the leaves to such an extent that the flower-forming material is either checked or absorbed by the parasite with the natural consequence that the flowers never develop and the constitution of the entire plant is ruined.

When a hardy plant like the Hollyhock is increased in large numbers with the aid of artificial heat, it is not unnatural that its once hardy constitution should undergo a change, become more delicate in fact, and thus be unable to resist the attacks of its natural enemies. Where Hollyhocks are allowed to stand

in the garden without any protection winter after winter, as they do in many cottagers' gardens, the Hollyhock fungus rarely or never makes its appearance. But on plants that have been raised from seeds or cuttings in heat, and protected in frames in winter it is almost sure to find a congenial home. One of the best and most natural preventives therefore against the fungus is to grow the plants without any protection whatever, but taking all necessary precautions to keep the soil clean, rich, and well-drained.

Remedies.—Many have been tried to rid the plants of the fungus, but they have been practically useless, except for a short time. Washes of soft soap and sulphur seem to have been useful in the early stages of the fungus, but not afterwards. Perhaps one of the best remedies for plants seriously attacked is to dissolve some permanganate of potash in almost boiling water, and spray the plants thoroughly with this by means of a very fine syringe. The water will lose much of its heat in transit from the syringe to the plant, and the tiny globules of water on the surface will be further cooled by the surrounding air, so that the actual temperature of the water when it strikes the fungus will probably not exceed 150° Fahr., and the sudden increase in temperature will probably kill the fungus outright. This suggestion must not be considered as tantamount to dipping the plant in boiling water. It has proved efficacious in the case of mildew on Vines in fruit without the slightest injury to the foliage, and if properly done should also be of service to the Hollyhock. If the plants are in a really bad condition and beyond all hope, it is safer to take them up carefully and without shaking them about violently so as to spread the fungus spores, and have them burned. If other plants are to take their place, the soil into which they are to go should be well watered a day or two beforehand with boiling water. This will kill any of the fungus spores which may be lurking in the crevices of the soil.

LAVATERA (TREE MALLOW).—A genus containing about 18 species of woolly or hairy trees or shrubs, with angled or lobed leaves, and flowers axillary, solitary, or in terminal racemes. Bracteoles of the involucre 3-6 cohering

about half way up. Calyx 5-lobed. Stamen-tube divided into numerous filaments.

L. arborea.—A stout-growing downy shrub 6-10 ft. high, native of British and S. European coasts. Leaves long-stalked, roundish, with 5-9 broad, short lobes. Flowers late in summer, about 2 in. across, purple, glossy. The form known as *variegata* is a very beautiful plant with variegated leaves, the surface of which is handsomely marbled with yellow and yellowish-white on a grey-green ground.

Culture and Propagation.—This species is best raised from seeds every year. They may be sown out of doors in April and May, or raised in gentle heat about March so that the seedlings will be ready for the open ground at the end of May. Plants raised the first year do not attain great dimensions, and it is better to keep them until the second so that they may appear at their best. In cold and unfavourable parts of the kingdom they will not stand severe winters, and in such places they must be wintered in a greenhouse or cold frame. The variegated form, which is the most popular, and is much used for sub-tropical gardening, is more tender than the green-leaved type, and consequently requires even greater protection in winter.

L. Olbia.—A rough-stemmed shrub about 6 ft. high, native of Provence, but now naturalised in some parts of the British Islands. Leaves soft, woolly, 3-5-lobed, the uppermost leaves oblong, almost entire. Flowers from June to October, reddish-purple, solitary, on short stalks.

Culture &c. as above for *L. arborea*. This species likes a light rich soil in open sunny situations, and during the summer months should be frequently watered.

L. trimestris.—A beautiful annual 3-6 ft. high, native of S. Europe, Asia Minor &c. Leaves smoothish, roundish, heart-shaped, upper ones lobed. The solitary flowers 2-3 in. across are freely produced from the beginning of July to October, and are of a beautiful transparent rose, with deeper coloured veins, and a purple blotch at the base of the petals. There is also a white-flowered variety, *alba*.

Culture and Propagation.—This fine species may be raised from seeds sown annually either in gentle heat in March.

or in the open border, where the plants are to bloom, in April and May. In the first case the seedlings must be pricked out and grown on till the end of May or beginning of June before transferring them to the outdoor garden. In the second they need only be thinned out 12 to 18 in. apart. In hot dry seasons they like plenty of water at the root. The white-flowered form of *L. trimestris* is very pretty.

L. unguiculata.—A woolly-stemmed, shrubby perennial, native of S.E. Europe, with acutely 3-5-lobed woolly leaves. Flowers in late summer, light rosy-lilac, about 3 in. across, axillary, on short stalks.

Culture &c. as above for *L. arborea*.

MALVA (MALLOW).—A genus of 16 species of smooth or hairy annual, biennial, or perennial herbs, with leaves often angled, lobed, or dissected. Flowers solitary or clustered, stalked or unstalked, or rarely in terminal racemes. Bracteoles 3, distinct; calyx 5-lobed, stamen-tube divided at the apex into numerous filaments.

Culture and Propagation.—The species described below are the only ones worth growing. They thrive in any fairly good garden soil, and may be used in borders, shrubberies or the wild garden. The annual kinds are raised from seeds; the perennials also, and by cuttings.

M. Alcea.—A European perennial about 4 ft. high, with light green, downy leaves palmately lobed and cut. Flowers in summer, about 2 in. across, pale rose-purple. The variety *fastigiata* (also known as *M. Morenii*) is a native of Italy, 2-3 ft. high, with lobed and toothed leaves, and red flowers produced from July to October.

Culture &c. as above. This species flourishes in ordinary good garden soil in warm sheltered positions, and seeds freely. It may be increased by sowing the seeds as soon as ripe in a cold frame, afterwards pricking the seedlings out when large enough into light rich soil in the frames, or in shallow pans or boxes. They are best kept under protection during the winter months, giving as much air and light as possible, however, on all occasions except in frosty weather. By the end of May or June they will be ready to plant in the outdoor garden 12-18 in. apart. In the milder parts of the kingdom seeds may also be sown in the open border in

April and May. During the summer months cuttings of the side shoots may be rooted in sandy soil under handlights and wintered in cold frames.

M. crispa.—An erect annual 2-6 ft. high, found naturalised in many countries but probably a native of China. Leaves smooth, angular, toothed, curled. Flowers in summer, white, pale purple at the tip, axillary, and almost or quite stalkless.

Culture &c. as above. This plant is highly ornamental owing to the pretty appearance of the crisp-edged leaves and bushy habit. It likes a rich well-drained soil and partially shaded situations with plenty of water during the hot summer months. It may be raised from seeds sown in gentle heat in March, pricking the seedlings out and transplanting at the end of May. Seeds may also be sown in the open border in April, and the seedlings afterwards thinned out about 2-3 ft. apart. In warmer parts of the kingdom seedlings will come up annually from self-sown seeds in autumn.

M. mauritiana.—An erect annual 4-6 ft. high, native of N. Africa and South Europe, with obtusely 5-lobed leaves, and numerous deep purple flowers in June.

Culture &c. as above for *M. crispa*.

M. miniata.—A bushy Mexican species 1½-2 ft. high, having oval 3-lobed toothed leaves, and axillary flowers of bright red or orange-red, borne in erect spikes from June onwards until cut down by frost.

Culture and Propagation.—This species, owing to the vivid colouring of its flowers, makes a very effective border plant when grown in masses. Although really perennial, it is scarcely hardy enough to stand out of doors during the winter months except in the very mildest parts of the south and west. It should therefore be raised from seeds and cuttings annually in the same way as *M. Alcea* above.

M. moschata (Musk Mallow).—A handsome British perennial 2-3 ft. high. Lower leaves kidney-shaped, cut; upper ones with 5 deeply pinnatifid, jagged segments. Flowers in summer, about 2 in. across, rose, in terminal and axillary clusters. The variety *alba* has beautiful pure white flowers.

Culture &c. as above for *M. Alcea*.

CALLIRHOE.—A small genus containing about 7 species of elegant annual

or perennial herbs, all natives of North America, usually with lobed or parted leaves, and similar in growth to the Mallows. Bracteoles 1-3, distinct, or none. Calyx 5-lobed. Stamen-tube divided at the apex into numerous filaments.

Culture and Propagation.—They may be grown and increased in the same way as the Mallows, and as mentioned below.

C. alcæoides.—An erect perennial species 2-3 ft. high, with deeply lobed leaves and rosy flowers about 1½ in. across borne during the summer and autumn months.

Culture &c. as for *C. digitata*.

C. digitata (*Nuttallia digitata*).—A glaucous perennial 2-3 ft. high, with somewhat peltate 6-7 parted leaves, cut into linear entire or 2-parted segments. Flowers in summer, reddish-purple, on long stalks.

Culture and Propagation.—This species thrives in ordinary well-drained garden soil, and likes rather warm sunny situations with plenty of moisture at the root during the summer months. It may be increased by sowing seeds as soon as ripe in cold frames, afterwards pricking the seedlings out and growing on in frames until the following April or May, when they may be planted out in mild showery weather. Seeds may also be sown out of doors in April and May in the milder parts of the country, but the plants will not bloom till late in the season. Cuttings of the side shoots may also be rooted in cold frames or under handlights during the summer months, and will make good strong plants by the following spring.

C. involucreta (*Malva involucreta*). A hairy-stemmed, procumbent perennial about 6 in. high, with leaves divided almost to the base, 3-5-parted; segments narrow lance-shaped, 3-5-toothed. Flowers in summer, about 2 in. across, crimson, shading off into white at the base, in the centre of which is a cluster of bright yellow-anthered stamens surrounding purple stigmas.

Culture and Propagation.—Although, if allowed to ramble over the surface of the soil, this plant only reaches a height of about 6 in., its stems nevertheless are 2-3 ft. long. They may be trained on a trellis or against a wall if desired, or if allowed to grow naturally the plant might be placed on a mound so as to allow the stems to trail downwards all round. They may be kept

in position by a few pegs here and there. Seeds are freely produced and may be sown as soon as ripe in cold frames or in spring in gentle heat. The seedlings may be planted out about the end of May. Being a native of Texas, and rather too tender to stand our winters except in the mildest parts of the south and west, propagation by seeds is the easiest method of increase for plants to be grown in the open air.

C. macrorhiza.—A thick-rooted perennial 2-3 ft. high, bearing erect racemes of purple-carmine flowers during the summer and autumn months. There are several shades of colour, including pale rose and rose-purple, but the white-flowered variety is very pretty.

Culture &c. as above for *C. involucreta*.

C. Papaver (*Nuttallia Papaver*).—*Poppy Mallow.*—A somewhat trailing perennial about 3 ft. high, with lower leaves lobed or pedate, the others being palmate-pedate or digitate or simple as they ascend the stem. Flowers from early summer to late autumn, bright purple-red, with ovate-acute fringed sepals.

Culture &c. as above for *C. involucreta*.

C. pedata.—A pretty trailing perennial (although usually treated as an annual) 2-3 ft. high, with laciniately pedate and trifid leaves, and panicles of cherry-red flowers each about 2 inches across produced during the summer and autumn months. The varieties *compacta* and *nana* are dwarfer and more compact in growth than the type.

Culture &c. as above for *C. involucreta*.

SIDALCEA.—A genus containing about 8 species of perennial herbs, like Mallows and Hollyhocks in growth, and with lobed and parted leaves. Flowers shortly stalked or sessile, in racemes or terminal spikes. Bracteoles none. Calyx 5-lobed. Stamen-tube doubled at the apex, the outer portion divided into 5 anther-bearing bundles, the inner into numerous filaments.

S. candida.—A native of Colorado, 2-3 ft. high, with roundish, glossy, 7-lobed, long-stalked leaves. Flowers in summer, white, freely produced in terminal racemes.

Culture and Propagation.—This species will flourish in ordinary good garden soil in open sunny situations and likes plenty of water at the roots during

the summer months. Although a true perennial it is best raised from seeds sown every year as soon as ripe in cold frames, or in spring in the same way, or in gentle heat. The seedlings must be pricked out so as to have space enough to develop into bushy plants. Those from summer or autumn seeds flower earlier and are finer plants than those raised from seeds in the spring. The latter bloom later in the season. Where the plants are not killed by winter frosts they may also be increased by division in early autumn or in spring, but seedling plants are usually more satisfactory.

S. malvæflora (*Callirhoe spicata*).—A slender, twiggy-stemmed species about 2-3 ft. high, native of Texas. Lower leaves roundish, 5-9-lobed and cut, the others variously lobed, cut, and toothed, the upper ones being almost entire. Flowers in summer, lilac or pale rose, less than 2 in. across, numerous. The variety *Listeri* has beautifully fringed pale pink flowers, borne on tall graceful spikes.

Culture &c. as above.

MALVASTRUM.—A genus containing 60-80 species of erect dwarf or trailing herbs or undershrubs resembling the Malvas and Sidas. Leaves various, entire, heart-shaped, or deeply lobed. Flowers scarlet, orange, or yellow, borne in the leaf axils or at the ends of the shoots. Bracteoles 1-3, small or none. Calyx 5-cleft. Stamen-tube divided into numerous filaments at the apex.

Culture and Propagation.—These plants flourish in warm sunny positions in ordinary good garden soil and are suitable for the herbaceous border or rock garden in the milder parts of the kingdom. Although more tender, on the whole they may be treated much in the same way as the Malvas, Sidalceas, and Callirhoes, and are increased by seeds sown as soon as ripe in cold frames or by cuttings of the side and basal shoots in autumn.

M. campanulatum (*Malva campanulata*).—A downy Chilean species 1-1½ ft. high, with large deeply lobed and divided leaves. Flowers late in summer, bright rose-purple, borne in long loose spikes at the ends of the shoots.

Culture &c. as above. This can only be considered hardy in the milder parts of the kingdom.

M. coccineum.—A native of the United States, about 6 in. high, with more

or less deeply lobed blue-green leaves and trusses of scarlet flowers from July to September. The variety *grossulariaefolium* grows 1½-2 ft. high, and has strong hairy stems and leaves, and red flowers.

Culture &c. as above.

M. Gilliesi (*Modiola geranioides*).—A pretty plant about 6 in. high, native of temperate S. America. It has trailing stems and palmately lobed leaves, and during the summer months produces bright red flowers.

Culture &c. as above. This is best grown in rich sandy and well-drained loam in warm sunny parts of the rock garden. In low damp places it is often killed in winter.

M. lateritium (*Malva lateritia*).—A hairy perennial, native of Montevideo. Although the stems are only about 6-12 in. high, they trail as much on the ground before rising. The beautiful salmon-pink flowers, each about 1½ in. across, with a purple blotch at the base of the petals, are borne in great profusion from June to September, singly on long stalks in the leaf axils.

Culture &c. as above. This species only ripens seed in hot favourable seasons. It may be, however, easily increased by severing the trailing stems which root at the joints, or by cuttings of the non-flowering shoots inserted in cold frames in autumn. These will produce sturdy plants by spring. Perfectly hardy only in the milder parts of the kingdom.

PLAGIANTHUS.—A genus containing about a dozen species of shrubs or rarely herbs with entire, sinuate, angulate, or rarely lobed leaves. Flowers often small, whitish, clustered in the leaf axils or in spikes at the ends of the shoots, rarely solitary, or arranged in short axillary panicles. Bracteoles none, or distant from the 5-toothed or lobed calyx. Stamen column divided at the apex into numerous filaments. Ovary usually 2-5-celled.

P. Lyalli.—A beautiful flowering shrub, native of New Zealand, where it attains a height of 20-30 ft. in the mountainous districts, and is said to be deciduous above an altitude of 3,000 ft., but evergreen below that level. The shortly stalked leaves are 2-4 in. long, ovate heart-shaped in outline, tapering at the apex, and deeply and doubly crenate on

the margins. The pure white flowers 1½–2 in. across are borne in drooping clusters in June on the previous year's growths, and are remarkable for the conspicuous bundle of yellow anthers in the centre.

Culture and Propagation.—This handsome shrub will flourish in the open air in the milder parts of the kingdom, but is almost sure to be severely injured if not killed in hard winters in northern parts. It is best grown against a wall with a more or less southern aspect, although it succeeds well as a bush in the south of Ireland, Cornwall &c. It likes a rich and well-drained sandy loam with a little leaf soil and manure added, and a top dressing in winter or in spring when growth is being made will also be beneficial and induce the plants to flower profusely. After flowering—say during July—the old wood should be cut out where necessary and the young shoots trained in and exposed to the sun and air so as to ripen well for blooming the following year.

This species may be increased by inserting cuttings of the more or less ripened shoots in sandy soil under hand-lights in late summer and autumn. Sometimes only a few cuttings root, and the riper they are probably the better. The lower branches may also be layered in autumn, and detached the following year when well rooted.

There are a few other species of *Plagi-anthus*—all natives of New Zealand or Australia—known, but they are now rarely, if ever, seen in cultivation. The following may be mentioned:—*P. betulinus*, with Birch-like leaves and terminal panicles of small whitish flowers; *P. divaricatus*, a marsh plant with small narrow leaves and whitish flowers either solitary or in clusters; *P. Lamperi* with whitish-yellow flowers; *P. pulchellus*, a shrub 3–4 ft. high, with heart-shaped leaves and small whitish flowers.

SIDA (INDIAN MALLOW).—A genus containing about 80 species of softly downy or woolly herbs or shrubs, with flowers sessile or stalked, solitary or clustered, axillary or in terminal heads, spikes, or racemes. Bracteoles none, or distant from the calyx. Calyx 5-toothed or lobed. Stamen-tube divided at the apex into numerous filaments.

The following are the only species suitable for outdoor cultivation, and may

be treated like the Mallows, Callirhoë, and *Sidalceæ*.

S. incarnata.—A showy Brazilian perennial about 2 ft. high, with smooth, deeply cut, and variously lobed and toothed leaves, fringed with short hairs. Flowers in summer, less than 2 in. across, pink, borne in close pyramidal spikes.

Culture &c. as for *S. Napæa*.

S. Napæa.—A smooth herbaceous perennial 4–10 ft. high, native of North America. Leaves 5-cleft, with oblong, pointed tooth lobes. Flowers in summer, large, white, in umbellate corymbs.

Culture and Propagation.—This species may be used in masses in the border, but the plants should not be too crowded. Seeds are freely produced every year and may be sown as soon as ripe either in cold frames or in gentle heat in spring. The seedlings in both cases are pricked out and grown on to be transferred to the open ground in mild weather in April and May. The plants may also be divided in early autumn or spring, but the same general treatment as recommended for *Sidalcea candida* will also suit this plant perfectly, see p. 276.

ABUTILON.—A genus containing about 70 species of soft, downy herbs or shrubs, rarely trees, with leaves often heart-shaped, angled or lobed, rarely narrow. Flowers usually axillary. Bracteoles none. Calyx 5-cleft. Stamen-tube divided at the apex into numerous filaments.

Culture and Propagation.—There are no *Abutilons* hardy enough to stand a frosty winter in the British Islands, except perhaps in the very mildest parts. In the winter of 1879–80 plants were uninjured out of doors at Bournemouth, but at Ryde in the Isle of Wight they were not unnaturally injured by 15° of frost. In most parts of the country nearly all kinds may be placed out of doors from the end of May till September, in rich turfy loam, peat, and leaf soil, with plenty of sand. In the very mild parts the following kinds may be tried permanently, with protection in the event of severe winters. They root readily from cuttings of the young wood in spring in a temperature of 65°–70°. When well rooted the plants are placed singly into small pots in rich soil, and kept shaded and moist for a few days until they become established. They are afterwards moved to a cooler place, and

gradually hardened off with plenty of air and sunshine, and will be ready for the outdoor garden by the beginning of June. Cuttings of the ripened shoots will also root readily in heat about August and September, and plants raised at this period will make fine specimens for planting out the following June if grown on in heat during the winter and early spring months, afterwards hardening them off as advised above. Seeds of Abutilons may be sown as soon as ripe or in spring in a temperature of 65°-70° Fahr.

A. Darwini.—A Brazilian species about 4 ft. high, with large, broad leaves, and finely cupped, bright orange flowers, with darker veins. There are many hybrids raised from this.

Culture &c. as above.

A. megapotamicum (*A. vexillarium*). A well-known species from the Rio Grande river with ovate acute toothed leaves and masses of drooping bell-shaped flowers, having deep red sepals, and pale yellow-brown petals with deeper coloured netted veins.

Culture &c. as above. This species is usually grown up pillars or on the roofs or sides of greenhouses, in which it is very ornamental during the autumn and winter months. In the south and west it is practically hardy in ordinary winters, as is also *A. vitifolium* below, and both are valuable for covering south walls.

A. striatum.—A free-growing Brazilian species, with large lobed leaves and orange-yellow flowers, veined with blood-red.

Culture &c. as above.

A. vitifolium.—A fine Chilean climbing shrub, suitable for walls. Leaves heart-shaped, 5-7-lobed, assuming a fine golden tint in autumn. Flowers in early summer, large, cupped, porcelain-blue. *A. Sellowianum marmoratum*, with beautifully marbled leaves, is a lovely plant.

Culture &c. as above.

HIBISCUS.—This genus contains 150 species of trees, shrubs or herbs, with leaves often lobed or variously cut. Bracteoles persistent or caducous, numerous, rarely 3-5, often narrow, free or united. Calyx 5-cleft or toothed. Stamen-tube truncate or 5-toothed below the apex, rarely anther-bearing, with numerous protruding filaments.

Culture and Propagation.—The following are the only species which grow well

out of doors in this country. They like a rich loamy soil and warm sunny positions to bring their flowers to perfection as early in the summer as possible, otherwise they will not bloom until autumn and may be spoiled by early frosts. The perennial kinds may be increased by seeds, or cuttings rooted under glass; the annual kinds from seeds sown in gentle heat about February or March, or in the open border in April and May.

H. Manihot.—A handsome shrub 6-9 ft. high, native of the Old World Tropics, with pedately lobed leaves 6 in. across, and beautiful soft yellow flowers 4-6 in. across, with a deep purple blotch at the base of each petal.

Culture and Propagation.—This plant is best treated as an annual, and may be raised from seeds sown in heat in February and planted out at the end of May. Seeds may also be sown as soon as ripe in cold frames or in gentle heat, and the seedlings may be grown on during the winter months under glass, until favourable weather in May, when they may be planted out.

H. militaris.—A fine perennial 3-4 ft. high, native of the United States. Leaves heart-shaped, toothed, more or less 3-lobed, downy beneath. Flowers rosy, about 4 inches across, bell-shaped, produced in late summer and autumn.

Culture &c. as above. This species should be grown in damp places.

H. Moscheutos.—A vigorous N. American perennial 3-5 ft. high, with large, ovate, pointed, serrate leaves, downy beneath. Flowers white, with a purplish centre, sometimes pale rose or purple.

Culture &c. as above.

H. palustris.—A native of the swamps and marshes of N. America, 3-5 ft. high. Leaves broadly ovate, bluntly serrate, downy and whitish beneath. Flowers large, bell-shaped, 3-4 in. across, white tinted with rose, and having a ring of deep purple at the base.

Culture &c. as above. This species requires to be grown in damp situations, where, however, it will have plenty of sunshine.

H. roseus.—An attractive species, 4-6 ft. high, naturalised in marshy spots in France, but native of N. America. Leaves large, broadly ovate, pointed, white beneath. Flowers large, rosy, solitary, about 4 in.

across, and spotted or blotched with purple at the base. *H. militaris* and *H. palustris* are considered to be botanical varieties of this.

Culture &c. as above for *H. palustris*.

H. syriacus (*Althæa frutex*).—A deciduous Syrian shrub 6-8 ft. high, with ovate wedge-shaped, 3-lobed, toothed leaves. Flowers in the type purple with a crimson spot at the base of each petal.

There are many varieties with colours varying from pure white, such as *totus albus*, to deep blue, like *caelestis*. There are also several very fine double-flowered varieties in various colours.

Culture &c. as above. This makes a beautiful flowering bush, and in the south and west looks very handsome out of doors.

H. Trionum (*H. africanus*).—*Bladder Ketmia*.—A beautiful hairy, branched annual, about 2 ft. high, native of Africa, S. Europe &c. Leaves heart-shaped, palmately lobed; lobes linear. Flowers yellow, 2-3 inches across, with a purple centre, produced from July to September and October.

Culture &c. as above, p. 279. Seeds of this handsome species may be sown in gentle heat in March, or in the open border in April and May in the warmer parts of the country. The plants prefer a light rich soil and sunny situations, with plenty of water in summer.

Closely related to this species is *H. vesicarius* (or *H. grandiflorus*) which has more deeply lobed and toothed leaves, and larger flowers.

XXV. STERCULIACEÆ

A natural order consisting of herbs, shrubs, or trees, with alternate or rarely nearly opposite, entire, toothed, or lobed leaves. Flowers regular, hermaphrodite or one-sexed. Calyx gamosepalous, more or less deeply 5-lobed. Petals 5, hypogynous, free, or adnate to the base of the staminal tube. Stamens often united at the base into a cylindrical or urn-shaped tube. Ovary free, 2-5-celled. Fruit a dry capsule, or rarely a berry.

This order contains over 40 genera and more than 500 species, mostly natives of tropical regions. The following genus is the only one representing the order in the open air in the British Islands.

FREMONTIA.—A genus represented by only one species:—

F. californica.—A beautiful deciduous Californian shrub, with brown stems 6-10 ft. high, and heart-shaped 5-7-lobed leaves, hairy beneath; the young shoots covered with a rich reddish-brown tomentum, and minute warts. Flowers in June, bright yellow, about 2 in. across, solitary on short stalks opposite the leaves. Calyx spreading, bell-shaped, deeply 5-lobed, with a depression at the base of each segment.

Petals none. Stamen-tube 5-cleft, with orange-red anthers.

Culture and Propagation.—This species thrives in a sandy loam, and should have a position facing west or south-west, but not too hot or dry. It may be increased by cuttings in spring, under a bell glass in gentle heat. When well rooted the plants may be potted up singly and grown on until they have become large enough for planting in the outdoor garden.

XXVI. TILIACEÆ—Lime Tree or Linden Tree Order

An order containing about 40 genera and over 300 species of trees and shrubs, rarely herbs. Leaves alternate, or in a few species opposite or nearly so, simple, penninerved or palminerved, entire, toothed, or rarely lobed. Stipules twin, usually small and deciduous, rarely large and persistent, or absent altogether. Flowers regular, hermaphrodite, or rarely 1-sexed, axillary or terminal, often cymulose. Sepals 5, rarely 3 or 4, free or connate. Petals as many in number, or fewer, or absent, usually with a small pit at the

base, alternate with the sepals, inserted round the base of the torus, entire or incised; twisted in bud or variously imbricated. Stamens usually many, hypogynous, free, or rarely cohering in a ring, or in 5-10 bundles. Ovary free, sessile.

TILIA (LIME TREE; LINDEN).—A genus of 8 species of tall ornamental trees with simple or stellate hairs. Leaves stalked, often obliquely cordate, serrate. Flowers white or yellowish in axillary or terminal cymes on the young growths, with a leafy bract half-winged, half-free, attached to the stalk. Sepals and petals 5, the former boat-shaped, the latter often with a scale at the base. Stamens many, free, or irregularly disposed in bundles. Fruit globose, nut-like, indehiscent, 1-2-seeded.

Culture and Propagation.—The Lime trees are stately ornaments of our landscape, either as solitary specimens on large lawns, or in avenues in parks. They like good loamy soil and do well everywhere except on exposed and hilly situations. They are usually increased by layers, which are fit for transplanting in about 12 months. Young trees that have been transplanted several times are best for starting in gardens. The choicer varieties are usually grafted on stocks of the common Lime. Seeds are very rarely ripened in this country, and even if they were it is not worth while going through the very slow process of raising plants from them. A good selection may always be obtained from nurserymen.

It may be mentioned that Russian Bast and the bast mats so much used for covering frames in winter are the product of the inner bark of various species of Lime tree.

T. americana (*American Basswood* or *White-wood*).—A North American tree 60-70 ft. high, with deeply heart-shaped, abruptly pointed, smooth, leathery, serrate leaves. Flowers in summer, yellowish-white, followed by yellow fruits as large as peas. *T. pubescens* is a variety with yellow flowers, and leaves 3-4 in. across, with short and broad serratures. There are several other forms or variations, in some of which the leaves are very large.

Culture &c. as above.

T. argentea (*T. alba*).—*White* or *Silver Lime*.—A native of E. Europe, 30-50 ft. high, with heart-shaped, some-

what pointed serrated leaves, unequal at the base, smooth above, downy beneath. Flowers in summer, yellowish-white, fragrant; petals with a scale at the base. Fruit yellow, ribbed.

Culture &c. as above.

T. cordata (*T. microphylla*; *T. parvifolia*; *T. ulmifolia*).—A small native tree, with ovate heart-shaped, smooth, pointed leaves, finely toothed, glaucous, and bearded in the axils of the nerves beneath. Flowers in summer, yellowish-white, petals without a scale at the base. Fruit globose or ellipsoid, hoary or downy, faintly ribbed.

Culture &c. as above.

T. dasystyla.—A tree 30-60 ft. high, native of the Crimea. Leaves obliquely truncate at the base, or somewhat heart-shaped, slightly hairy beneath and bearded in the axils of the nerves. Flowers in summer, yellowish-white; style downy at the base.

Culture &c. as above.

T. heterophylla (*American White Basswood*).—A North American tree 30-50 ft. high, with leaves 4-8 in. across, very oblique, more or less heart-shaped, abruptly pointed, shining green above, white and downy and conspicuously nerved beneath. Flowers in summer, greenish-yellow, with blunt, crenulated petals.

Culture &c. as above.

T. petiolaris (*T. alba pendula*; *T. americana pendula*; *T. argentea pendula*).—A Crimean species 50 ft. or more high, with drooping branchlets. Leaves pale green above, white with a hoary down beneath. Flowers in July, yellowish-green, with 5 petal-like scales among the stamens. Fruit globose, 5-lobed, warted.

Culture &c. as above.

T. platyphyllos (*T. grandifolia*).—This is our native large-leaved Lime tree, 70-90 ft. high, differing very little from *T. cordata* in foliage and flowers. Leaves sometimes downy on both surfaces, but always underneath. Flowers in June, yellowish-white; petals without scales. Fruit obovate, globose, 3-5-ribbed when

ripe. The variety *laciniata* has curiously cut leaves, and is dwarfer and less vigorous than the type; *aurantia* has orange-yellow twigs; *blechiana* is a distinct and strong-growing variety with very large leaves; *pyramidalis* is pyramidal in growth; *vitifolia* has lobed, vine-like leaves.

Culture &c. as above.

T. vulgaris (*T. europæa*; *T. intermedia*).—*Lime, Lin, Linden, or Line tree*.—A S.E. European plant naturalised in this country. Leaves smooth above, obliquely heart-shaped, bearded in the axils of the nerves beneath. Flowers in June and July, pale yellow; petals without a scale at the base. The variety *variegata* is recognised by its leaves having creamy-white blotches.

ARISTOTELIA.—A small genus having a few species of evergreen shrubs, with usually almost opposite, entire, or toothed leaves. Flowers axillary or lateral, racemose, often polygamous. Sepals 4-5, valvate. Petals 4-5, 3-lobed, toothed or almost entire, thickened round the base of the torus. Stamens many. Fruit a berry, small, indehiscent.

A. Macqui.—A handsome Chilean shrub, about 6 ft. high, with oblong acute,

smooth, shiny, toothed leaves, and small greenish axillary flowers borne in May. The pea-like berries are very deep purple, becoming black when fully ripe. The variety *variegata* is more ornamental than the type, but not quite so hardy.

Culture and Propagation.—This is a good plant for the shrubbery, and will grow well in ordinary soil. Cuttings of the ripened or partially ripened shoots under a hand-glass root freely in sandy soil during the summer and autumn months. They may be grown in frames until spring, and then planted out. Fresh plants are also obtained by layering the branches in late summer and autumn.

A. racemosa.—An ornamental deciduous shrub or small tree, native of New Zealand, where it grows 6-20 ft. high. It has rather large irregularly shaped leaves of a bright and pleasing green, and produces its greenish flowers in racemes in May.

Culture &c. as above. This species does not seem to be quite hardy except in the milder parts of the kingdom. It flourishes on a south wall and is chiefly valuable for the ornamental appearance of the foliage. It may be raised from imported seeds or by cuttings in the same way as *A. Macqui*.

XXVII. LINEÆ—Flax Order

A small order of smooth or rarely hairy or tomentose herbs, shrubs, or rarely trees. Leaves alternate, or very rarely opposite, simple, entire, or slightly serrate-crenate. Flowers regular, hermaphrodite, usually terminal, in racemes, panicles, corymbs, heads, clusters, or spikes. Sepals 5, rarely 4, free, or united below. Petals 5, rarely 4, hypogynous, or rarely slightly perigynous, often twisted; usually blue, yellow or white, rarely rose, very fugacious, or persistent in a few genera. Stamens equal in number to the petals, with a similar number of staminodes, often twice—rarely thrice—as many.

LINUM.—A genus containing about 80 species of smooth or rarely downy herbaceous plants, sometimes shrubs, with alternate, or very rarely opposite, narrow, entire, one- to many-nerved leaves. Stipules absent or glandular. Flowers in terminal or axillary racemes, panicles, or clustered cymes, yellow, blue, or rarely rosy, crimson, or white. Sepals 5, entire. Petals 5, twisted, very fugitive. Stamens united below, hypogynous, alternate with the petals; staminodes equal in number, minute or bristle-like. Glands

5, small, adnate to the stamen-tube, opposite the petals. Styles 5, usually free.

Culture and Propagation.—All the Linums are free-flowering and ornamental. The annual species are easily raised from seeds, and so are the perennials, which may also be divided or increased by cuttings. The latter should be taken in summer and inserted in a shady place under glass.

The plants will grow in ordinary garden soil, but where a feature is made of them they may be grown in well-drained sandy

loam, to which may be added a little peat or leaf mould. In bleak or northerly parts of the British Islands, the plants should have warm, sheltered positions. Unless otherwise stated, the species described below are all perennials.

To secure the finest and most brilliant effects *Linums* should be grown in large patches, and the colour of their flowers should always be taken into consideration when massing them with plants of other colours, so that a harmonious result is obtained.

L. alpinum.—Native of Europe, 6 in. high, with linear, awl-shaped leaves, full of pellucid dots. Flowers in summer, large, blue, 8-9 on each stem.

Culture &c. as below for *L. flavum*. This is well suited for the rockery or for massing in the front of the flower border.

L. angustifolium (*Pale Flax*).—A smooth, glaucous, native species about 1-2 ft. high, with sharp linear-lance-shaped leaves. Flowers from May to September, less than 1 in. across, pale lilac-blue.

Culture &c. as below for *L. flavum*.

L. arboreum.—A beautiful dwarf shrub about 1-1½ ft. high, native of Crete, with bluntly wedge-shaped, recurved leaves. Flowers in early summer, yellow, 1½ in. across.

Culture and Propagation.—This is an evergreen species, and when grown in sheltered spots retains its freshness during the winter months. Grown as a pot plant in a cool or slightly heated greenhouse, it may be had in bloom in February and March. Seeds are rarely ripened, but plants are readily obtained by means of cuttings of the more or less ripened shoots during July and August. They may be inserted in sandy soil in a cold frame, and kept shaded and damp until rooted. Afterwards the plants should be given as much light and air as possible, except in very frosty weather, and by April and May they will be fit for transplanting to the flower border, or against a wall, according to locality. They require slight protection during severe winters in northern parts of the kingdom, although hardy in ordinary winters in the neighbourhood of London.

L. austriacum.—A smooth Austrian species 1-2 ft. high, with linear lance-shaped acute leaves, covered with pellucid

dots. Flowers in summer, pale bluish-purple. Closely related to *L. perenne*.

Culture &c. as below for *L. flavum*.

L. campanulatum.—A glaucous plant, about 1 ft. high, native of S. Europe. Lower leaves rounded at the apex, the others more or less broadly lance-shaped. Flowers from June to August, bright yellow, borne in corymb-like cymes.

Culture and Propagation.—This species is closely related to *L. flavum*, and it is possible that hybrids between the two exist. It is as a rule too tender to stand our winters except in the mildest parts of the south and west, and like *L. arboreum* it rarely produces good seed in our climate. New plants, however, may be obtained from cuttings taken in July and August and inserted in a cold frame in the way described under *L. arboreum*.

L. flavum.—A handsome species 12-18 in. high, native of Austria and Hungary, with sharp narrow lance-shaped leaves, without stalks. Flowers in summer, golden-yellow, freely produced, but in more compact heads than those of *L. campanulatum*.

Culture and Propagation.—This species resembles *L. arboreum* in appearance and blossom, and also *L. campanulatum*, but its stems die down in winter. It is, however, much hardier than these other two species, and throws up vigorous shoots in spring. Seeds are also freely produced in favourable seasons, and new plants may be obtained by sowing them in the open border as soon as ripe, in a warm sheltered position. They do not, however, germinate till spring, and then the seedlings may be either pricked out into good rich soil or thinned out 12-18 in. apart. Warm sunny positions are best, and shade should be avoided, so as to get a greater abundance of blossom.

L. grandiflorum.—A beautiful smooth Algerian annual 6-12 in. high, with linear lance-shaped acute leaves, and large rose-coloured flowers 1½ in. across in summer.

Culture and Propagation.—By sowing seeds at intervals plants may be had in bloom from May to October. Plants for flowering from October onwards in the greenhouse may be obtained by sowing seeds in pots in summer and giving plenty of water. There are several forms in cultivation, the best known being *coccineum*, *roseum*, *rubrum*, and *splendens*.

L. Macraei (*L. Chamissonis*).—This Chilean species is somewhat tender, but will grow well outside from May to October. It is about 1 ft. high, with stiffish lance-shaped pointed leaves, and orange flowers.

Culture &c. as for *L. monogynum*.

L. monogynum.—A shrubby-stemmed New Zealand plant 1 ft. high, with lance-shaped leaves. Flowers in summer, white, about 1½ in. across. The variety *candidissimum* is a superior plant to the type, having larger and finer flowers and a more compact habit.

Culture and Propagation.—This species is easily increased from seeds sown as soon as ripe in cold frames. The seedlings may be transplanted in mild weather in spring in the same way as those of *L. flavum*. Cuttings of the more or less ripened shoots may also be rooted in cold frames as recommended for *L. arboreum*.

L. narbonense.—A somewhat glaucous smooth plant, 2 ft. high, native of S. Europe. Leaves lance-shaped linear, very acute, rather stiff. Flowers from May to July, sky-blue with violet veins, sometimes white, in loose corymbs.

Culture and Propagation.—This is one of the finest of the blue-flowered *Linums* and will flourish in almost any soil. It is quite happy even on dry, poor soil, and not only flowers with great freedom but produces seed freely. These may be sown as soon as ripe in the same way as recommended for those of *L. flavum* above.

L. nervosum.—A native of E. Europe, 12–18 in. high, with smooth lance-shaped pointed leaves. Flowers in summer, blue, large, with slightly notched or pointed petals, crenate at the apex.

Culture &c. as above for *L. flavum*.

L. perenne.—A native evergreen species 12–18 in. high, with narrow linear-lance-shaped acute leaves. Flowers in summer,

1 in. across, usually bright blue, but pink or white in some varieties.

Culture &c. as for *L. flavum* and *L. narbonense*.

L. salsoloides.—A somewhat shrubby evergreen, 1 ft. high, native of S.W. Europe, with smooth, linear leaves. Flowers in summer, ½ in. across, white with a purple centre.

Culture &c. as above for *L. monogynum*.

L. sibiricum.—A smooth Siberian species 3–4 ft. high, with large beautiful blue flowers. Closely related to *L. perenne*.

Culture &c. as for *L. flavum*.

L. tauricum.—An evergreen shrubby species about 1½ ft. high, native of the Caucasus. Leaves glaucous, spoon-shaped or lance-shaped. Flowers from June to August, yellow.

Culture &c. as above for *L. arboreum*.

L. usitatissimum (*Common Flax*).—A beautiful smooth European annual about 1½ ft. high, with lance-shaped or linear-acute-leaves, and blue flowers in summer.

Culture &c. as above for *L. grandiflorum*. This is the species so largely grown in Ireland and elsewhere for the production of flax, but it is also useful as a border plant.

L. viscosum.—A Pyrenean plant 1–2 ft. high, with lance-shaped, slightly downy leaves, covered with viscid glands. Flowers in summer, about 1 in. across, pale purple or lilac, with deeper veins. They often last well into November and December.

Culture and Propagation.—This is a good plant for the rock garden, where it can be established. It likes warm sunny positions and the same treatment generally as *L. arboreum*. It may be increased from cuttings taken in July and August, and inserted in sandy soil in cold frames in the same way as recommended for *L. arboreum*.

Series II. DISCIFLORÆ (see p. 123)

XXVIII. GERANIACEÆ—Geranium and Pelargonium Order

An order containing about 750 species of herbs (sometimes climbing) or undershrubs, rarely trees, smooth or often clothed with a glandular down. Leaves opposite or alternate, often 2-stipuled, toothed, lobed, dissected, very

rarely entire. Peduncles often axillary, one-flowered or somewhat umbellately many-flowered, rarely cymose or racemose. Flowers hermaphrodite, regular or irregular. Sepals 5, rarely fewer, free or sometimes united to the middle, imbricate, rarely valvate, the upper one spurred in some genera; persistent or rarely deciduous. Petals 5, or by abortion fewer or absent, hypogynous or somewhat perigynous, variously imbricated, rarely twisted. Torus with 5 glands alternate with the petals, or glandless. Stamens usually ten, rarely more or fewer. Fruit either a 3-5-lobed capsule, or separating into cocci, rarely a berry.

GERANIUM (CRANE'S BILL).—A genus with about 100 species of herbs, rarely shrubs, with opposite or alternate, toothed, or usually palmately lobed leaves, usually stipulate. Peduncles axillary, 1-2-flowered. Flowers regular, sepals and petals 5, hypogynous; glands 5, alternate with the petals. Stamens usually 10, of which 5 are sometimes imperfect. Carpels 5, separating below and curling upwards when ripe around a central column resembling a bird's bill—hence the popular name.

Culture and Propagation.—Geraniums grow readily in ordinary well-drained garden soil, and are well adapted for the rock garden, margins of borders, banks &c. They may be increased from seeds sown in spring or autumn, in warm sheltered parts of the open border, or better still in shallow pans or boxes in cold frames. When the seedlings are well developed they may be pricked out 2-3 inches apart and grown on until they again almost touch. During mild weather in spring they may be planted in the flower garden 1½-2 ft. or more apart according to vigour. A very simple and easy method of increasing most Geraniums is by division of the rootstock. This work is performed about the end of September, or not later than October, or in mild weather in spring as growth is commencing.

In order to see Geraniums at their best, the plants when once established should not be disturbed for 3 or 4 years. A good mulching of well-rotted manure may be placed around the crowns of the plants in early winter, to act not only as a shelter to the roots during severe frosts, but also to replenish the soil with nutritious food for them in spring. At the latter period the manure may be very lightly forked into the soil just beneath the surface, if desired.

Note.—The plants popularly called

'Geraniums' in gardens are in reality Pelargoniums (see p. 288).

G. albanum (*G. cristatum*).—A native of S.E. Europe, 1 ft. high, with kidney-shaped, 7-lobed and toothed leaves. Flowers in May, purple, on hairy stalks.
Culture &c. as above.

G. argenteum.—A beautiful alpine 2-3 in. high, native of N. Italy. Leaves long-stalked, hoary or silky on both sides, 5-7-parted and cut. Flowers in summer, large, pale rose with darker veins.
Culture &c. as above.

G. armenum.—A vigorous and very handsome Armenian species, about 2 ft. high, with rather smooth stems and leaves, the latter being 5-lobed and more or less toothed at the base. The loose leafy cymes of flowers appear in June and July, and are very effective owing to the brilliant purple colour of the petals, each of which has a deeper purple blotch at the base, from which veins radiate over the surface.

Culture and Propagation.—This species is practically hardy in ordinary winters, and may be increased from seeds—which are freely produced—or by division as stated above.

G. asphodeloides (*G. subcaulescens*). Native of S. Europe, about 6 in. high, with very downy 5-lobed and cut leaves. Flowers in summer, usually purplish-violet.

Culture &c. as above.

G. atlanticum.—An Algerian species 12-18 in. high. Leaves roundish, cut nearly to the base into 5-7-lobed, cut and toothed segments. Flowers in June, 1½ in. across, pale purple with red veins. This species is also known as *G. malvaeflorum*.

Culture &c. as above.

G. cafferum.—A S. African species 9 in. or more high. Leaves 1-3 in. across, hairy above, 3-5-lobed, with several acute, irregular teeth. Flowers in June, pale lilac or white, with obovate petals.

Culture &c. as above.

G. cinereum.—An almost stemless Pyrenean plant about 6 in. high. Leaves covered with glaucous down, 5-7-parted and cut. Flowers in summer, pale red with dark stripes.

Culture &c. as above. Owing to its dwarf habit and compact growth this species may be used for making borders to flower beds, and is also well adapted for the lower parts of the rockery. It likes a light well-drained soil.

G. collinum.—Native of E. Europe, with angular, somewhat decumbent, downy stems. Leaves palmately 5-parted, lobed and deeply serrated. Flowers in early summer, purplish-violet; petals entire, roundish; flower stalks and calyx covered with clammy hairs.

Culture &c. as above.

G. dahuricum.—A native of Dahuria 1 ft. high, with opposite, 3-5-parted, acutely lobed leaves. Flowers in June, purple; petals entire, much bearded at the base.

Culture &c. as above.

G. Endressi.—A Pyrenean plant 1 ft. high. Leaves opposite, 3-5-lobed, acute, serrate. Flowers in summer, pale rose, with darker veins; petals oblong ovate, entire, fringed at the base.

Culture &c. as above.

G. eriostemon.—A Nepalese species 6-36 in. high. Leaves 5-lobed, deeply toothed, lower ones long-stalked, alternate, upper ones sessile, opposite. Flowers in June, pale violet; stamens white, purple at the top; petals bearded at the base.

Culture &c. as above.

G. ibericum.—A showy Caucasian species about 1 ft. high. Leaves hairy, 5-7-parted, pinnately lobed, toothed. Flowers in summer and autumn, large, blue; petals orbiculate or somewhat 3-cleft. The variety *platypetalum* is a taller hairy plant with a profusion of deep violet flowers streaked with red.

Culture &c. as above.

G. Lamberti.—A native of Nepal about 18 in. high. Leaves heart-shaped, softly hairy on both sides, 5-lobed,

cut and toothed. Flowers in summer, large, bright lilac.

Culture &c. as above.

G. lucidum.—A native annual or biennial 6-12 in. high, with roundish, shining, 5-lobed leaves. Flowers from May to August, bright rose, about $\frac{1}{2}$ in. across.

Culture &c. as above. Increased by sowing seeds annually, either out of doors in warm parts of the kingdom, or in cold frames in less favoured spots.

G. macrorhizon.—A native of South Europe, 1 ft. high, with smooth, 5-parted deeply toothed and lobed leaves, often spotted with brownish-red. Flowers from May to July, deep red or bright purple; calyx globose, swollen.

Culture &c. as above.

G. maculatum.—A N. American species 1½ ft. high, with 3-5-parted, deeply toothed and lobed leaves, lower ones long-stalked, upper sessile. Flowers in summer, pale lilac.

Culture &c. as above.

G. phæum.—A native of Central and W. Europe, naturalised in Britain, about 1½ ft. high. Leaves 5-9-lobed, deeply toothed. Flowers in early summer, dark brown, almost black, with a white spot at the base of each entire petal. The variety *lividum* has dull purplish flowers; and the variety *roseum* has rose-coloured blossoms.

Culture &c. as above. This species seems to prefer partially shaded spots in the rockery or flower border.

G. pratense.—A beautiful British plant 2-3 ft. high, with round, downy stems. Leaves 7-parted, cut into linear, deeply serrated lobes. Flowers in summer, large, blue flushed with violet, and borne in corymb-like panicles. There is a fine double blue and a double white-flowered variety.

Culture &c. as above.

G. robertianum (*Herb Robert*).—A common but pretty British species 6-9 in. high, with 3-5-parted lobed leaves. Flowers in summer, bright crimson, $\frac{1}{2}$ in. across. The variety *album* has white flowers.

Culture &c. as above.

G. sanguineum.—A fine native species 1-2 ft. high, with hairy 5-7-parted leaves, the lobes again divided into 3-5 narrow

segments. Flowers in summer, crimson or blood-red, about $1\frac{1}{2}$ in. across. The variety *lancastricense* has large flesh-coloured flowers with purple veins. It grows only 4-6 in. high. There is also a white-flowered form of *G. sanguineum*.

Culture &c. as above. This species flourishes in light sandy soils, and is excellent for massing in the flower beds, borders, rockeries, banks &c.

G. striatum.—A native of S. Europe with 3-5-lobed cut and toothed leaves. Flowers from May to October, pink, with darker veins; petals notched.

Culture &c. as above.

G. sylvaticum.—A British plant 2-3 in. high, with 5-7-lobed, deeply toothed leaves. Flowers in summer, less than 1 in. across, purple or blue, with crimson veins; white in the variety *album*.

Culture &c. as above. A good plant for edgings and borderings, and also for the rock garden in light well-drained but moist soil.

G. tuberosum.—A native of S. Europe, 9 in. or more high, having a roundish tuberous rootstock and knotted forked stems. Leaves many-parted, with linear pinnatifid serrated lobes. Flowers in early summer, purple, large, numerous, with deeper coloured veins, petals 2-cleft. There is a variety called *Charlesi* from Afghanistan which may be recognised by having a series of roundish superimposed tubers, and by the leaf segments being less lobed than in the type.

Culture &c. as above. In cold northern parts of the kingdom it may be advisable to cover the tuberous rootstocks with bracken or a heap of dry leaves in severe winters. In such localities the roots should be planted rather deeply, as a further protection, but the soil must be thoroughly well drained.

ERODIUM (HERON'S BILL; STORK'S BILL).—A genus of about 50 species of pretty herbs, very rarely shrubs, often with jointed knotty branches. Leaves opposite or alternate, toothed, lobed, or often pinnately dissected. Peduncles axillary, with flowers usually in umbels. Flowers regular or scarcely irregular. Sepals 5, imbricate. Petals 5, hypogynous, imbricate, 2 upper ones sometimes deficient. Stamens 5, alternating with the 5 scale-like staminodes. Disk of 5 glands, alternate with the petals. Ovary

5-lobed. Tails of carpels spirally twisted and curling upwards.

Culture and Propagation.—Erodiums, which omit a strong peculiar smell when bruised, thrive in a sandy well-drained soil in sunny places, and are excellent plants for the rock garden or border. They are easily increased by division of the rootstock, either in early autumn or in spring, or from seed sown in cold frames either as soon as ripe or in spring. Indeed, there is practically no difference in the treatment of *Erodiums* and *Geraniums*, which resemble each other a good deal in appearance and blossom. The cultural remarks under *Geranium* may be applied to each of the following species.

E. alpinum.—A native of the S. Italian mountains, with rather smooth, twice pinnately cut leaves. Flowers from spring to autumn, purple, about 1 in. across, 6-10 in an umbel.

Culture &c. as above.

E. carnifolium.—A native of the Spanish mountains 6-10 in. high. Leaves alternately pinnate, 8-9 in. long, leaflets deeply cut, twice divided, the midrib covered with soft, downy hairs beneath. Flowers in spring and early summer, red, about $\frac{1}{2}$ in. across, 8-10 in an umbel.

Culture &c. as above.

E. hymenodes (*E. trilobatum*).—A native of the Atlas Mountains 6-15 in. high, with somewhat 3-lobed, very blunt, deeply toothed leaves. Flowers in spring and summer, pink, the upper petals with a red-brown blotch at the base.

Culture &c. as above.

E. macradenum (*E. glandulosum*).—A stemless Pyrenean plant about 6 in. high. Leaves twice divided, forming tufts, clothed with a glandular down, and possessing a peculiar aromatic fragrance. Flowers in summer, pale violet, or flesh colour, with purple-rose veins, the two upper petals having a dark spot at the base.

Culture &c. as above.

E. Manescavi.—A native of the Pyrenees 1-2 ft. high. Leaves pinnate, with oblong, deeply cut leaflets. Flowers in summer, purplish-red, from 5-15 in an umbel-like truss.

Culture &c. as above.

E. pelargoniflorum.—A native of Anatolia with ovate cordate leaves springing from the roots. Flowers in summer, white spotted with purple, 8-10 in an umbel.

Culture &c. as above.

E. petraeum.—A stemless Pyrenean plant 3-6 in. high. Leaves rather smooth, pinnate, with deeply divided segments, and lance-shaped linear lobes. Flowers in early summer, bright rose, or white and veined, but not spotted.

Culture &c. as above.

E. Reichardi.—A native of Majorca, only 2-3 in. high, with small heart-shaped, crenate, blunt, smoothish leaves. Flowers from April to September, solitary, white faintly veined with pink.

Culture &c. as above.

E. romanum.—A S. European biennial 6-9 in. high, with pinnate leaves having ovate deeply cut leaflets. Flowers from April to September, purplish, several on a stalk.

Culture &c. as above.

E. trichomanefolium.—A stemless plant 4-6 in. high, native of Mount Lebanon. Leaves bipinnate, hairy, rather glandular, with oblong linear lobes. Flowers in summer, flesh-coloured, with darker veins, about 4 on a stalk.

Culture &c. as above.

PELARGONIUM (STORK'S BILL).—A genus of smooth or downy perennial herbs or undershrubs, with opposite, rarely alternate leaves, entire, toothed, lobed or variously cut, stipulate. Peduncles axillary, opposite the leaves, 2 or more on an umbel, rarely 1-flowered. Flowers irregular. Sepals 5, imbricate, united at the base, the upper one produced into a spur adnate to the pedicel. Petals 5, or fewer by abortion, slightly perigynous, dissimilar. Stamens 10, hypogynous, united at the base, usually 7 with fertile anthers. Ovary 5-lobed, beaked.

There are about 170 wild species of Pelargonium, natives chiefly of S. Africa, and requiring greenhouse treatment. The genus is important because from it are derived the various sections of Bedding Pelargoniums (popularly called Geraniums used in hundreds of thousands annually for beds and borders. The species described below (with the exception of *P. endlicherianum* and *P. quercifolium*) are mentioned chiefly on account

of their connection with the Bedding 'Geraniums.'

P. endlicherianum.—A native of the Taurus Mountains in Asia Minor, 1½-2 ft. high. Lower leaves roundish, notched and toothed, the upper ones more or less deeply divided into 3-5 lobes. Flowers in late summer, deep rose, large, the 2 larger petals marked with 5 deep purple nerves.

Culture and Propagation.—This species is hardy in mild parts of the country, and thrives in sandy well-drained loam in a warm nook of the rockery. It may be increased by means of seeds or cuttings in the same way as *P. zonale* below.

P. inquinans.—A native of S. Africa about 2 ft. high, with roundish, kidney-shaped, downy leaves, crenate on the margins and almost undivided or very slightly lobed. Flowers in summer, varying from intense scarlet to rose and white, many on a stalk; petals broadly obovate.

This is the parent of the well-known Scarlet 'Geranium.' It has no dark zone on the leaf as in *P. zonale*, and has broader and shorter petals than that species.

Culture &c. as for *P. zonale* below.

P. peltatum (*P. hederacfolium*; *P. lateripes*; *P. scutatulum*).—A S. African species, with shrubby, straggling stems, and smooth or downy, Ivy-like, 5-angled or lobed leaves. Flowers in summer, white or red, varying in size, several on a stalk.

This is the origin of the well-known Ivy-leaf 'Geranium.' This section has now become very valuable owing to the numerous fine double and semi-double flowered varieties. They are chiefly used for window boxes, vases &c., but if planted in round raised beds by themselves, with their stems trailing over the surface of the soil, they look very ornamental. Indeed this is their natural method of growing, and not trained up sticks or trellises upon which they have to be carefully and regularly tied to keep them in order. Their culture and propagation are the same as for the Zonal Pelargonium described below.

P. quercifolium.—This is so well known as the 'Oak-leaf Geranium' that it deserves mention. It is a shrubby plant 3 ft. or more high, with leaves cut and lobed like small Oak-leaves, and strongly scented. Flowers in summer.

purple or pink, more or less veined, 3-5 or more on a stalk.

P. zonale (*Horseshoe* 'Geranium').—A shrubby plant 2 ft. or more high, with roundish, smooth or downy leaves, usually with a dark horseshoe-like zone, crenate toothed on the edges and slightly lobed. Flowers in summer, varying from scarlet and crimson to red and pure white, many on a stalk.

The numerous varieties of Pelargoniums (Zonals, Silvers, Tricolors, Bronzes &c.) used in bedding out are derived from hybrids obtained by crossing *P. zonale* with *P. inquinans*. The processes of selecting and crossing have gone on for nearly 200 years, and the progeny obtained are in no way like their parents. In the Zonal Pelargonium proper, it has been the aim of the gardener to get rid of the dissimilarity in the petals, and to obtain flowers in which every petal shall be equal, the whole forming a perfectly circular outline without a break between the petals. How far he has succeeded may be seen at any exhibition; not only are the flowers perfectly symmetrical in outline, but the size of the individual blooms, or 'pips' as they are technically called, has been greatly increased, and they are often larger than an ordinary watch.

Culture.—The outdoor cultivation of the Pelargonium is extremely simple. About the end of May or beginning of June according to locality and state of the weather, plants may be put into beds or borders containing ordinary well-dug soil, if a rich, sandy loam so much the better. Sometimes the varieties are mixed or kept separate according to the taste of the planter, but in any case they should not be nearer than 6 to 9 inches, or even more, as they soon make bushy growth.

Propagation.—The plants are usually increased by cuttings, which may be taken at any time as long as they are not too sappy. From June to August, however, is the best time out of doors. The cuttings may be inserted 2-3 in. apart in a prepared spot with a fair amount of sunshine, and by September they will have made good growth and plenty of roots. They should then be potted up singly in small pots and kept in a greenhouse or cold dry frame during the winter or in any light airy place where they will not be touched by frost. If possible the temperature during the winter months should

not fall below 45° or 50° Fahr., and only very little water is required. If too much moisture is in the soil or atmosphere, the leaves and young growths are attacked with a fungus which soon causes them to decay. The best remedy against this is to raise the temperature by artificial means, such as hot-water pipes, and keep the greenhouse or frame in which the plants are grown in a fairly dry condition.

Where Zonal Pelargoniums can be grown in greenhouses during the winter months to keep up a good supply of bloom it is necessary to keep the temperature up to about 65°-70° Fahr., and the atmosphere overhead should not be charged with moisture to any great extent. The plants are usually raised from cuttings taken in spring and rooted in gentle heat, either singly in small pots, or in shallow boxes or pans. When well rooted they are potted up and grown on as mentioned above. No blossoms, however, are allowed to develop. As they appear they are pinched out with the finger and thumb, and all the energy of the plant is devoted to strengthening its constitution for flowering during the winter months. From the beginning of June to the end of September the plants should be stood out in the open air in a warm sunny position, and if kept well watered, and the shoots and blossoms pinched out, they will make fine bushy specimens by the end of the season. In the case of cuttings and seedlings, when well rooted, the tip of the main shoot should be pinched out. This will induce the side buds to make branches, and thus give the plant a dwarfer and sturdier habit. If pinching is neglected, the plants become lanky and weak, and do not flower so freely.

Zonal Pelargoniums may also be easily raised from seeds sown in August or September as soon as ripe. They germinate freely, and if the seedlings can be kept safe from frost during the winter, they will be fine and sturdy for planting out in early summer. In this way many new forms are likely to be obtained, and if any are really an improvement on existing varieties they may be retained and increased by cuttings in the way described above.

The above remarks apply to all sections of Pelargoniums. It will, however, be found that some varieties, especially among the 'Tricolors,' are

somewhat more difficult to propagate and grow into good plants than others.

There are some hundreds of varieties in cultivation, but the following are among the very best for outdoor gardening:—

Best Scarlets and Crimson.—Vesuvius, West Brighton Gem, Henry Jacoby, John Gibbons, Rev. A. Atkinson, Ball of Fire, Corsair, King of the Bedders, Geo. Potter, Triomphe de Stella, Wonderful.

Silver-leaved varieties.—Flower of Spring, Day-break, Mrs. Parker.

Tricolors.—Mrs. Pollock, Master Harry Cox, Lady Cullam, Countess of Ashburnham, Peter Grieve, Sophia Dumaresque.

Green and Gold.—Crystal Palace Gem, Happy Thought, Golden Christine, Robert Fish.

Bronze.—Zulu, Marshall McMahon, Black Douglas, Golden Harry Hieover, Bronze Queen, Bronze Beauty.

Ivy-leaves.—Album grandiflorum, Duke of Edinburgh, l'Elegant, Dolly Varden, Souvenir de Charles Turner, Madame Crousse &c.

Pinks.—Master Christine, Mrs. Turner, Constance, E. F. Crocker.

Whites.—White Vesuvius, White Princess, White Perfection, Queen of the Whites.

TROPÆOLUM (GOLDEN NASTURTIUM; INDIAN CRESS; YELLOW LARKSPUR).—A genus of about 35 species of beautiful twining or spreading annuals or perennials, with alternate peltate or palmately angled, lobed or dissected leaves. Stipules none, or minute. Peduncles axillary, 1-flowered. Flowers irregular, orange-yellow, rarely purple or blue. Sepals 5, united at the base, the upper one produced into a free spur. Petals 5, dissimilar, or fewer by abortion, often fringed or bearded at the base. Stamens 8, free, unequal, all anther-bearing. Fruit 3-lobed, fleshy, indehiscent.

Tropæolums are extremely valuable for training over trellises, arbours, old tree stumps, sheds, old walls &c. in the summer and autumn months, during which period their masses of peculiar-looking flowers and brilliant colours give a very gay appearance to the garden.

This genus is familiar on account of the dwarf and climbing varieties of *T. majus* and *T. minus*, popularly called

'Nasturtiums' simply. The Nasturtium proper belongs to the same order as the Wallflower and Cabbage (*Cruciferæ*).

Culture and Propagation.—Tropæolums are annual and perennial, the latter having either fibrous or tuberous roots. The annual varieties thrive in ordinary garden soil and may be raised from seeds sown out of doors in April. The perennial kinds like a richer soil—turfy loam and peat, with plenty of moisture at the root when growing. They may be increased by dividing the roots or tubers, or by inserting cuttings of the young shoots in pots or pans under glass.

The following are the best for outdoor gardening:—

T. Lobbianum.—A vigorous climbing annual, native of Columbia, with roundish peltate leaves, obscurely lobed, glaucous beneath. Flowers in summer, orange; calyx long-spurred, hairy; petals obovate, the 2 upper ones entire, scarcely lobed, the 3 lower ones smaller, deeply toothed, fringed, long clawed.

There are several beautiful varieties of this species, among which mention may be made of *Brilliant*; *Crystal Palace Gem* (or *elegans*); *fulgens*; *Golden Queen*, with pure golden-yellow flowers without spots; *hederæfolium*, with Ivy-like leaves of a dark metallic hue and deep crimson-scarlet flowers; *Napoleon III.*, yellow spotted with brown; *Spitfire*, with scarlet flowers and deep purplish foliage.

Culture and Propagation.—Seeds may be sown out of doors in April and May in patches where the plants are required to bloom during the season. They may also be sown in pots or shallow pans in cold frames or greenhouses in gentle heat about March, afterwards transplanting the seedlings at the end of May or beginning of June. If the seeds are sown in pots it will be unnecessary to prick the seedlings out separately, but the whole—pot, soil, and all—may be planted where required, thus avoiding injury to the roots and subsequent 'flagging' of the leaves.

T. majus (*Great Indian Cress* or *Nasturtium*).—This well-known climbing annual is a native of Peru. Leaves almost round, peltate, sometimes slightly lobed or wavy. Flowers in summer and autumn, rich orange, large and showy, the 2 upper petals marked with deep

red-brown. There are several varieties of this species, with crimson, scarlet, orange, and striped flowers. The *Tom Thumb* section is valuable for bedding or for the edges of borders &c. A few of the best dwarf kinds are *Empress of India*, bright crimson; *Golden King*, golden-yellow; *King of Tom Thumbs*, scarlet; *King Theodore*, deep crimson; *Pearl*, creamy-white; *Ruby King*, rosy-scarlet; *Vesuvius*, brilliant scarlet.

Among the double-flowered kinds *Grandiflorum plenissimum*, double yellow, with a deep maroon blotch at the base, and *Hermine Grashoff*, scarlet, are the best.

Culture &c. as above for *T. Lobbianum*.

T. minus.—This resembles *T. majus* but is smaller and weaker growing. The flowers are deep yellow, streaked with orange and red; the petals end in a bristly point. The plant is also a native of Peru. There is a variety called *coccineus*, which has a yellow calyx spotted with carmine, and deep scarlet-crimson petals with a scarlet beard.

Culture &c. as above for *T. Lobbianum*. This small growing species is valuable for making edgings to beds and borders, or for furnishing the base of tall naked-stemmed trees &c.

T. pentaphyllum (*Chymocarpus pentaphyllum*).—A vigorous tuber-rooted climber, native of Buenos Ayres, with slender purple stems, slightly twisted and branched. Leaves about 2 in. across, cut into 5 oblong entire, smooth leaflets. Flowers in summer. Calyx dull purple, 1½ in. long, greenish, marked with deep purple within; petals bright vermilion, small, roundish, somewhat clawed.

Culture and Propagation.—This species likes warm sunny spots and good soil, and may be used for covering pillars, bowers &c. in the same way as *T. Lobbianum*, *T. majus* &c. The tuberous roots are best planted in April or May in light and well-drained sandy soil, with which a little well-rotted leaf mould or manure has been incorporated. Seeds may be sown under glass soon after ripening, and the young plants are best protected in green-houses until about the end of May when the weather will be favourable enough as a rule for planting them out. During the winter months, especially if severe frosts prevail, the tubers should be protected

with a covering of dry leaves, ashes, or sand, which will also serve to ward off heavy rains.

T. peregrinum (*T. aduncum*; *T. canariense*—of gardens).—*Canary Creeper*. A well-known graceful climbing annual (or greenhouse perennial), native of Peru and Mexico. Leaves somewhat kidney-shaped, 3-5-lobed. Flowers from June to October, bright canary-yellow, rather small, but very numerous; petals narrow, the 3 lower ones fringed; spur hooked.

Culture &c. as above for *T. Lobbianum*. This species is grown in thousands every year, and is to be seen all over the country, hanging down from cottage windows, or climbing a trellis by the door, and utilised in various other ways. It likes partially shaded situations and plenty of moisture at the root, although it is essential to have the soil well drained.

T. polyphyllum (*Yellow Rock Indian Cress*).—A prostrate Chilean species, very free in growth. The trailing stems 3-4 ft. long are densely covered with stalked glaucous leaves each cut into about 8 obovate-lanceolate segments. Flowers in June, singly from the axils of the leaves, bright yellow, the 2 broader petals spotted with red. The variety *Leichtlini* (said to be a hybrid between *T. polyphyllum* and *T. edule*) differs chiefly in having deep orange-yellow flowers and less glaucous leaves.

This plant dies down in autumn, but its tuberous roots are best left undisturbed for a few seasons. The young shoots appear in early spring.

Culture &c. as above for *T. pentaphyllum*.

T. speciosum (*Flame Nasturtium*).—A splendid Chilean climber, with downy, hairy stems, and 6-lobed almost peltate leaves, downy beneath. Flowers from June to September and October, beautiful scarlet; petals obovate, the upper ones narrowly wedge-shaped, the lower ones roundish. Spurlong.

Culture and Propagation.—This species does not grow or flower equally well in all places. It does best in light deep loam, with the addition of peat, leaf soil and sand. In summer a mulching of well-rotted manure is beneficial. It dislikes a position where it is likely to be scorching hot, and should therefore be planted in a somewhat shaded place where there is plenty of moisture in the

air—such as against bushes or hedges with a west or northern aspect. The tubers may be planted in April or May according to season and locality, and the plants may then be allowed to take care of themselves. If coddled too much they are likely to be a failure, but so long as the soil is well drained and fairly good, and the position partially shaded and not too cold, the plants will sooner or later establish themselves. As bearing these remarks out, the reader is referred to the observations on this species at p. 81.

T. tuberosum.—A beautiful tuberous-rooted climber, 2-4 ft. long, native of Peru, with smooth 5-lobed leaves, transversely truncate at the base. Flowers in late summer, scarlet and yellow, with entire or toothed petals.

Culture &c. as above for *T. pentaphyllum*. In unfavourable parts of the country it is safer to lift the tubers in autumn, and store them like Dahlias in a dry place for the winter.

LIMNANTHES.—A genus of 3 species of smooth, spreading annuals, with alternate, dissected leaves, without stipules, and axillary 1-flowered peduncles. Flowers regular, white, yellow, or rose. Sepals 5, valvate. Petals 5, twisted. Torus flattish, dilated, with 5 glands. Stamens 10, free, nearly perigynous. Fruit 5-lobed, indehiscent.

The following is the only species generally grown:—

L. Douglasi.—A showy Californian annual about 8 in. high, with pinnate leaves and stem trailing along the surface of the soil. Flowers from spring to autumn, yellow, passing into white streaked with grey, sweet-scented, about $\frac{3}{4}$ in. across. There are a few variations from the type in cultivation, the best known being *grandiflora*, which has somewhat larger flowers.

Culture and Propagation.—This species is useful for beds, borders or rockeries, and grows well in ordinary soil. Once established the seeds will sow themselves and reproduce young plants every year without trouble. When required in particular spots, seeds must of course be sown there in either March or September according to the time the flowers are wanted. In cold northern parts it will, however, be safer to sow the seeds at either of the periods mentioned

in cold frames, afterwards pricking the seedlings out about the end of May.

BALBISIA.—A genus with only one species here described:—

B. verticillata.—A very ornamental Chilean evergreen shrub, 3-6 ft. high, with opposite or alternate, often 3-parted leaves, without stipules. Flowers late in summer, regular, yellow, solitary, on long stalks. Sepals and petals 5, the latter twisted, hypogynous. Stamens 10, hypogynous, free.

Culture and Propagation.—This shrub is hardy only in the mildest parts of the country, and should be protected from severe frosts. It may be increased by seeds, or by cuttings of the half-ripened wood, under a bell-glass or hand-light during the summer and autumn months. The rooted cuttings should be grown on in frames or greenhouses until mild weather in spring, when they may be planted out in warm sheltered positions. They like a well-drained sandy loam.

OXALIS (Wood Sorrel).—A large genus containing over 200 species, of which only a few are useful for outdoor gardening. They are herbs or rarely dwarf shrubs, with usually 3-lobed, Clover-like leaves. Flowers regular, on axillary or radical, one or more flowered stalks. Sepals and petals 5, the latter hypogynous, twisted in bud. Disc none. Stamens 10, free or united at the base. Styles 5, distinct, short, long or medium.

Culture and Propagation.—The Wood Sorrels thrive in a sandy soil in warm, dry places. They may be grown in masses in borders or beds, or in clumps here and there in the rockery. As many of the species have a bulb-like fleshy rootstock, the offsets from these may be used to increase the plants. The best time to divide the plants is in spring just as growth is about to commence. They increase very rapidly in favourable situations, but few except the native kinds can be regarded as hardy in the British Islands except in the mildest parts of the south and west. The foliage usually dies down in autumn, and if the tuberous kinds are planted 4-6 in. deep they will survive ordinary winters. In the event of severe frosts, a covering of coco-nut fibre, dry leaves &c. is advisable to protect the dormant roots. Seeds if obtainable may also be sown in spring in gentle heat, afterwards pricking the seedlings out.

There is only one drawback to most of the beautiful flowered Oxalis: and that is the peculiarity of closing their flowers except during the brightest sunshine. When fully expanded in the sun they present a really fine sight.

O. Acetosella (*Common Wood Sorrel*; *Stabweort*).—A native of moist, shady places in the British Islands. Leaves 3-lobed, with obovate, somewhat downy leaflets. Flowers from April to August $\frac{1}{2}$ – $\frac{3}{4}$ in. across, white, veined with purple. Some plants produce also a smaller and shorter stalked flower, which does not open, but fertilises itself and produces seed.

Culture &c. as above. Increased by division and seed. The young tender leaves are sometimes used as a salad.

O. arenaria.—A Chilean species about 4 in. high, with a rootstock of fleshy scales. Leaves with 3 or 4 two-lobed, obovate leaflets, glaucous beneath. Flowers bright violet-purple, over an inch across, 3–10 on a stalk.

Culture &c. as above. Increased by division.

O. Bowiei.—A brilliant bulbous perennial 6–10 in. high, native of S. Africa. Leaves divided into 3 blunt obovate lobes, slightly downy beneath. Flowers in summer, rich rosy-red, about $1\frac{1}{2}$ in. across, yellowish inside at the base, several on a stalk.

Culture &c. as above. This fine species is often used for bedding out, making a rich border. Increased by division.

O. corniculata.—A small downy annual or biennial, found almost everywhere except the coldest regions. Leaves stipulate, 3-foliolate. Flowers from spring to autumn, yellow, with emarginate petals. The variety *rubra* has handsome bronzy foliage.

Culture &c. as above. Useful as a carpeting plant.

O. elegans.—This tufted species, about 6 in. high, is a native of the Andes at an elevation of about 7,000 ft. The leaves are composed of 3 wedge-shaped leaflets, about 1 in. long, green above, purple beneath. The rich purple flowers, each about 1 in. across, are produced in umbels of 6–9 during the summer months.

Culture &c. as above. This is quite hardy in favourable parts of the south and west.

O. enneaphylla.—A native of Fuegia about 4 in. high. Leaves with from 9 to 20 leaflets, usually in 2 series, smooth, glaucous, more or less wedge-shaped. Flowers in June, white or pale rose, nearly $1\frac{1}{2}$ in. across, sometimes with pale purple veins and a watery green centre.

Culture &c. as above. This species has proved hardy at Kew, planted in the rockery in a rather moist and shaded position. It is best, however, protected from heavy rains during the winter sleep of its ovoid bulb-like tubers, the largest of which are sometimes 2 in. long.

O. floribunda (*O. rosea*).—A Chilean species 9–12 in. high, with 3-foliolate leaves. Leaflets obovate. Flowers in summer, rosy, with darker veins.

Culture &c. as above.

O. hirta.—A very variable S. African species with thin decumbent leafy stems, each leaf being almost stalkless and cut into 3 narrow lobes about $\frac{1}{2}$ in. long. The rich purple, lilac, or violet flowers are about $1\frac{1}{2}$ in. across, and appear singly in the axils of the leaves. Sometimes the whole length of the stem—12–18 inches—is clothed with the blossoms, and the plant then looks charming.

Culture &c. as above.

O. lasiandra.—A beautiful Mexican species 9–18 in. high, with digitate leaves; leaflets 3 in. long, ovate spoon-shaped, wavy, spotted with crimson beneath. Flowers in summer, crimson, finely downy outside, about 20 on a stalk, and each about 1 in. across.

Culture &c. as above.

O. lobata.—A stemless Chilean species about 3 in. high, with 3-lobed leaves rather glaucous beneath. Flowers in late summer, bright yellow, spotted or pencilled with red in the centre.

Culture &c. as above. Increased by division.

O. luteola.—A bulbous-rooted South African species about 3 in. high, with 3-lobed leaves, having obovate leaflets. Flowers from early spring to autumn, over an inch across when fully open, soft creamy-yellow, one on a stem.

Culture &c. as above.

O. stricta.—A North American species $1\frac{1}{2}$ ft. high, naturalised in various parts of Britain, with 3-lobed leaves; leaflets obovate. Flowers in summer and autumn, yellow, 2–6 on a stalk.

Culture &c. as above. Increased by division.

O. tetraphylla (*O. Deppei*).—A very handsome Mexican species, with large scaly, bulb-like rootstocks, and 4-lobed hairy leaves like a Maltese Cross, glaucous beneath. Flowers in summer, lurid red or purplish-violet, many on a stalk.

Culture &c. as above. Increased by division. The young leaves of this species may be eaten as a salad. The fleshy white roots are tender and juicy but somewhat tasteless.

O. valdiviensis.—A charming Chilean annual 6-8 in. high, with 3-lobed leaves, and deep yellow flowers, streaked with red, especially outside.

Culture &c. as above.

O. variabilis.—A native of the Cape with a large bulbous rootstock from which springs a tuft of shortly stalked leaves with 3 roundish dark green and usually hairy leaflets. The cup-like flowers are fully 2 in. across when fully open, and are borne singly on erect stalks about 3 in. high. The colour varies from purple to rosy-lilac, white, or white and yellow.

Culture &c. as above. Increased by division.

O. violacea.—A N. American species 3 in. high, with black spindle-shaped bulbs. Leaflets 3, obovate, smooth, reddish underneath. Flowers from spring to autumn, pink, 3-9 on a stalk.

Culture &c. as above.

IMPATIENS (TOUCH-ME-NOT).—A somewhat large genus of herbs, sometimes shrubs, usually smooth, rarely downy or hairy. Leaves alternate, opposite or radical, serrate or toothed, without stipules, often with glands at the base of the stalks. Peduncles axillary, solitary, or clustered, one- to many-flowered, the upper ones forming a terminal panicle. Flowers irregular. Sepals 3, very rarely 5, coloured, imbricated, 2 side ones flat, 2 front ones, when present, small, the upper one produced into a hollow spur. Petals 3, the front one outside concave, the side ones 2-cleft (formed of 2 petals united), the upper lobe exterior. Disc glands none. Stamens 5. Capsule 5-celled, the valves open suddenly and with elasticity.

Culture and Propagation.—The hardy species of *Impatiens* thrive in any garden soil and reproduce themselves

annually without trouble, degenerating into vigorous weeds unless checked. They are scarcely suitable for the choice flower border, but may be utilised in the wilder parts of the garden or waste places. The cultivation of the Balsam—*I. Balsamina*—is specially noticed.

The British Yellow Balsam, *I. noli-me-tangere*, is found in moist, mountainous situations, and is a somewhat pretty plant. *I. tricornis* is an Indian annual, also with yellow flowers. It makes a bushy plant 3-5 ft. high, having purplish stems and oval oblong toothed leaves.

I. amphorata.—A Himalayan annual 3-6 ft. high, with succulent branching stems. Leaves bright green, often with pink edges and midrib, 3-6 in. long, broadly lance-shaped, pointed, finely crenate-serrate. Flowers in late summer, pale purple, suffused and speckled with rosy-red; racemes 2-5 in. long, many-flowered.

Culture &c. as above. Increased by seeds.

I. Balsamina (*Balsamina hortensis*). *Common Balsam*.—The wild species is a native of tropical Asia, 1-2 ft. high, with lance-shaped, serrated leaves. Flowers in summer, rosy-red.

This is the parent of the well-known Garden Balsam, at one time grown in immense quantities. The double-flowered varieties, such as the *Camellia-flowered*, *Rose-flowered*, *Solferino*, *Kermesina*, *alba*, *rosea*, *violacea* &c., variously striped and coloured, are chiefly grown, and when done well, are exceedingly handsome.

Culture and Propagation.—The seeds should be sown thinly in slight heat about the end of March in sandy, but not too rich, soil. When the seedlings are about 2 in. high, they should be put singly into 3-inch pots in fairly rich soil, with the roundish seed leaves close to the surface. By the end of May or beginning of June the plants will be ready for planting out in beds by themselves or in clumps in borders in warm, sunny positions, where they should receive plenty of water during the summer. They absorb water greedily, and are very sensitive to its absence. It is astonishing, however, to see the way in which plants which are almost shrivelled up for want of water will revive with a good soaking, and the tenacity of life in such a soft and juicy plant is really marvellous.

I. candida.—A showy Himalayan annual 6 ft. high, with narrow lance-shaped pointed leaves, in whorls of three, and pink, serrated edges. Flowers in late summer, white, slightly speckled with crimson.

Culture &c. as above. Seeds may be sown indoors as recommended for the Balsam, or in the open air in April and May.

I. fulva.—A N. American annual 2-4 ft. high, with ovate, coarsely toothed leaves. Flowers from June to September, orange-yellow, thickly spotted with reddish-brown.

Culture &c. as above. This species

is now naturalised in the British Islands.

I. glandulifera.—A native of Ceylon 4-6 ft. high, with lance-shaped, glandularly serrate leaves in whorls; stipules glandular. Flowers in summer, rosy. This species spreads rapidly in gardens.

Culture &c. as above.

I. Roylei.—An Indian annual 6-10 ft. high, with more or less lance-shaped, sharply serrated leaves in whorls. Flowers in summer, purple. There are two or three forms of this species, which has been confused with the preceding one.

Culture &c. as above.

XXIX. RUTACEÆ—Rue Order

A large order containing about 650 species of shrubs or trees, very rarely herbs, remarkable for having numerous glandular spots on the leaves and flowers, often containing pungent, strongly scented, bitter juices. Leaves without stipules, often opposite, simple or often compound, 1-3-5-foliolate or pinnate, very often entire, occasionally serrulate. Inflorescence various, very rarely spicate or umbellate, usually cymose and axillary. Flowers usually hermaphrodite. Sepals 4-5, imbricate, free or united. Petals 4-5, hypogynous or perigynous, broadly imbricated, rarely valvate. Stamens inserted at the base or on the edge of the disc, 4-5, or 8-10, rarely fewer or more, free, or rarely cohering or united to the petals. Styles short or long, distinct or connate. Fruit a capsule or berry, rarely a drupe.

RUTA (RUE).—A genus of about 40 species of strong-smelling perennial herbs or undershrubs with round, branching stems, and alternate, simple, 3-foliolate, pinnatisect or decomposed leaves. Flowers yellow or greenish, usually cymose. Calyx 4-5-lobed or parted, persistent. Petals 4-5, often toothed or ciliated, imbricated. Disc thick, urn-shaped, with 8-10 glands or pits. Stamens 8-10 inserted at the base of the disc, one short, one long, alternately.

Culture and Propagation.—The Rues thrive in light, rich soil, but only a few are of any garden value. They may be increased by seeds or cuttings in a shady border. The seeds may be sown out of doors as soon as ripe or in spring, afterwards pricking the seedlings out about 6 in. apart when well above the surface. As the plants increase in size they require more space, but transplanting should only be done in mild weather in spring or autumn. Cuttings of the ripened shoots

will root freely in autumn, especially if placed in a cold frame or under a hand-light. Sometimes old bushy plants may be divided. Once established in a garden the Rues may be allowed to look after themselves for years. If cut back every two or three years, new and vigorous shoots will be developed.

R. albiflora (*Boeninghausenia albiflora*).—An elegant downy plant 2 ft. high, native of Nepaul. Leaves very much cut and finely divided, glaucous, pubescent. Flowers borne in great profusion from July to September, white; petals entire, shorter than the stamens.

Culture &c. as above.

R. graveolens (*Common Rue*; *Countryman's Treacle*; *Herb of Grace*). A well-known glaucous perennial 2-3 ft. high, native of S. Europe, found in almost every garden, no doubt chiefly on account of its medicinal virtues. Leaves much divided into oblong-obovate segments.

Flowers from June to September, greenish with entire or slightly toothed, boat-shaped petals.

Culture &c. as above. The leaves are sometimes used for seasoning.

DICTAMNUS (*Dittany*; *Burning Bush*; *Fraxinella*).—A genus with only one species:—

D. Fraxinella.—A strong-smelling herb, shrubby at the base, 1-2 ft. high, native of S. Europe, with alternate unequally pinnate leaves, having 4-5 pairs of finely serrulated leaflets. Flowers from May to July, pale lilac-rose, feathered with purple veins. The variety *alba* has white, unveined flowers, and white stamens with yellow anthers. Calyx 5-parted, deciduous, lower segments longest. Petals 5, the 4 upper ones ascending in pairs, the lower one bent downwards. Disc annular, fleshy. Stamens 10, bent down, free, inserted with the petals at the base of the disc.

Culture and Propagation.—This plant thrives in light, loamy, well-drained soil, and in partially shaded situations. It may be increased either by seeds sown as soon as ripe, or better still by cutting the fleshy roots into pieces in the spring. The seeds may be sown in cold frames, but very often will not germinate until the following spring. The seedlings are then pricked out into light rich soil, and grown on with one or two removals until they are large enough for the flower border. It takes two or three years to obtain good flowering plants from seeds. The *Dictamnus* may also be increased by cuttings of the root about 2 in. long inserted in light rich soil in gentle bottom heat early in the year. They produce good plants quicker than seeds.

As ornamental border plants, both the red and white forms of *D. Fraxinella* may be placed in the front rank for the beauty and profusion of their flowers, and the generally beautiful aspect when well established. One of the most remarkable features of the plants, especially during the flowering season, is the fact that the fragrant oil or resin which exudes from the rusty-coloured glands is capable of being ignited on a dark summer's night. The plant may thus easily be distinguished from all others in the vicinity, not only by this phenomenon, but also by the very strong and at the same time agreeable odour which pervades the atmosphere.

CHOISYA (MEXICAN ORANGE FLOWER).—There is only one species in this genus:—

C. ternata.—A beautiful Mexican shrub 4-10 ft. high, readily recognised by its opposite, ternate, smooth, shining green leaves, full of pellucid dots. Flowers in summer, white, sweet-scented, freely produced on axillary stalks near the ends of the branches, and reminding one of those of the orange. Sepals 5, membranous, deciduous, imbricate. Petals 5, membranous, spreading, oblong. Stamens 10, inserted at the base of the disc, the alternate ones longer. Disc columnar, thick, erect, hairy.

Culture and Propagation.—This fine shrub thrives in light, rich soil with a south or west aspect, and will soon make a good bush in congenial quarters. It may also be grown against a wall, and if not hacked about too much with the knife its shoots will be laden annually with clusters of sweet-scented Orange-like blossoms.

Ripened cuttings strike freely in sandy soil under a glass in gentle heat during spring or early summer. Layers may also be made. In the mild southern parts of the kingdom, as in Cornwall, the Mexican Orange often flowers twice and sometimes three times a year, and will bear several degrees of frost without injury. In such places cuttings may be also freely rooted in cold frames or even in the open border.

ZANTHOXYLUM (TOOTHACHE TREE; PRICKLY ASH).—This genus is sometimes spelt *Xanthoxylyum* or *Xanthoxylon*. It contains about 80 species of smooth or downy shrubs or trees, with or without spines or prickles. The alternate leaves are unequally pinnate or 3-foliolate, and the small white or greenish polygamous flowers are borne in axillary or terminal cymes or clusters. Calyx 3-5-cleft. Petals 3-5, very rarely none. Stamens 3-5, hypogynous. Carpels 1-5, oblique, 1-celled, becoming dry or juicy fruits when ripe.

Z. americanum.—This is the common Toothache Tree of N. America. It grows 12-15 ft. high, and its leaves are composed of 9-11 ovate and slightly serrate leaflets, the roundish leaf stalks being furnished with prickly stipules at the base. The small whitish flowers are produced in clusters in the leaf axils about March and April.

Culture and Propagation.—This species will grow in ordinary good garden soil, and may be used in shrubberies, although it is scarcely worth planting when so many better trees are now in cultivation. It may be increased by rooting cuttings of the ripened shoots under a handlight or in a cold frame in sandy soil.

PTELEA.—A genus containing 6 species of unarmed shrubs or small trees with bitter bark. Leaves alternate, rarely opposite, 3-foliolate or pinnately 5-foliolate; leaflets ovate or oblong with pellucid dots, entire or serrate. Flowers polygamous, cymose or corymbose. Calyx short, 4-5-parted, imbricate. Petals 4-5, much longer than the calyx, imbricate. In the male flowers disc inconspicuous; stamens 4-5. In the female flowers, stamens effete, disc short. Style short; stigma 2-3-lobed. Fruit roundish, broadly 2-3-winged, 2-3-celled, indehiscent.

P. trifoliata (*Hop-tree*; *Swamp Dog-wood*).—A N. American shrub 4-8 ft. high, with 3-foliolate, yellowish, long-stalked leaves, which suggest Hops when bruised. Flowers in early summer, small, greenish; filaments densely hairy below the middle, longer than the style in the sterile flowers, shorter in the fertile ones. The variety *aurea* has beautiful golden-yellow foliage when young. The winged seed vessels are very attractive and bear a superficial resemblance to the fruits of the common Elm, but are much larger, and 3-winged, each wing being handsomely veined with a conspicuous branching network.

Culture and Propagation.—This ornamental shrub will flourish in ordinary good garden soil and may be increased by inserting cuttings of the ripened or half-ripened shoots in sandy soil under a handlight. Seeds are freely produced and new plants may be raised from these if sown as soon as ripe in cold frames.

SKIMMIA.—A genus of about half-a-dozen species of very smooth evergreen shrubs, with alternate, simple, stalked lance-shaped, entire, leathery leaves, pellucidly dotted. Flowers clustered in branched terminal panicles. Calyx short, 4-5-lobed, imbricate. Petals 4-5, oblong, much longer than the calyx, valvate or slightly imbricate. Disc inconspicuous. Stamens 4-5, hypogynous, effete in the female flowers. Fruit an ovoid, fleshy, 2-4-stoned drupe.

Culture and Propagation.—Skimmias thrive in a good loam and peat soil, well-drained. They are increased by cuttings in sandy soil under a bell-glass in heat, or from seeds sown as soon as ripe. The branches may be also layered. As border plants or in beds by themselves, they look very effective, especially when covered with bright red berries. For town gardens the Skimmias are excellent plants, as their smooth deep green foliage is uninjured by grime or dirt, while the beautiful coloured berries peeping out here and there render them extremely ornamental in autumn and winter.

S. Fortunei.—A pretty Japanese species 3-4 ft. high, with its deep glossy green Laurel-like leaves 3-4 in. long, and white or greenish-white flowers, followed by scarlet or dull crimson berries in the autumn.

This plant has been called *S. japonica* for many years. As a good deal of confusion still exists regarding the names of the cultivated Skimmias, it may be as well to point out that *S. Fortunei* (of Masters) differs from *S. japonica* (of Thunberg) in its dwarfer habit, the deep green colour of its lance-shaped leaves, and in having always hermaphrodite flowers, that is blossoms containing stamens and pistil. *S. Fortunei* also bears its ornamental berries with great freedom, whereas *S. japonica* does not unless carefully fertilised. The variety *argentea* has the leaves margined with white, while *rubella* is distinguished from the type by the reddish tints of the flower buds.

Culture &c. as above.

S. japonica.—Until a few years ago this species went under the name of *S. oblata*. It is a beautiful Japanese shrub 2-3 ft. high, with bright green elliptic-obovate leaves 3-5 in. long, borne close together on the branches and giving the plant a dense bushy appearance. The flowers are sometimes hermaphrodite and staminate only on the same plant; but sometimes a plant bears female flowers (pistils) only, and sometimes male flowers (stamens) only. Plants with male flowers only never bear any berries, while female flowers must be fertilised with pollen, or they will be equally barren.

There are many forms of *S. japonica* in gardens, and they were at one time regarded more or less as distinct species. The best known are *S. fragrans*, *S. fra-*

grantissima, *S. Foremani*, *S. macrophylla*, *S. intermedia* and *S. oblata ovata*.

Culture &c. as above.

S. Laureola (*Laureola fragrans*).—A somewhat ornamental Himalayan shrub with a rather strong if not actually disagreeable odour, by which it may be readily distinguished from its more popular relatives. It grows 3–4 ft. high, and has deep green oblong lance-shaped leaves, 3–5 in. long, narrowed at each end and yellowish-green beneath. The pale yellow strongly scented flowers appear in spring, and are replaced in autumn by smooth ovoid berries resembling the fruits of the Olive.

Culture &c. as above. This species is not very much grown, and is not nearly so hardy as the other kinds mentioned. It is fairly hardy in the Thames Valley, but in more northern parts would probably require protection in severe winters.

S. Rogersi.—This is probably a hybrid between *S. Fortunei* and *S. japonica*. It has greenish or dull purple shoots furnished with more or less lance-shaped leaves 3 in. or so in length, with margins slightly recurved. The flowers are usually hermaphrodite as in *S. Fortunei* and are succeeded by large deep crimson berries in autumn.

Culture &c. as above.

CITRUS (ORANGE).—A genus of trees or shrubs often spiny, with alternate dotted leaves, having a winged stalk jointed with the blade. Flowers hermaphrodite, very fragrant. Calyx cup-shaped or urn-shaped, 3–5-cleft. Petals 4–8, linear oblong, thick, imbricate. Stamens 20–60, variously united, or in many bundles. Disc large, cup-shaped, ringed; style smooth, deciduous, with a

capitate, lobed stigma. Fruit a globose or oblong, fleshy, many-celled berry, with a rind, of which the Orange and Citron are good examples.

Culture and Propagation.—The species of Orange mentioned below are the only ones which can be grown out of doors in this country in the mildest parts, and even they require protection in severe winters. They are worth growing for their appearance—glossy green leaves with a profusion of white-scented flowers and sometimes many fruits. They will flourish in good garden soil, and are best sheltered from the cold winds from the north and east. Fresh plants may be obtained by means of seeds sown as soon as ripe in gentle heat. Cuttings of the plump and firm young shoots may also be inserted in sandy soil in gentle heat under a bell-glass until rooted. The branches may also be layered out of doors in autumn and budding and grafting may be performed on stocks raised from seed.

C. japonica (*Kumquat*).—A shrub 4–6 ft. high, native of China and Japan, with bright yellow fruit. It requires plenty of water in summer, but should be kept dry in winter. It is frequently grafted on *C. trifoliata*.

Culture &c. as above.

C. trifoliata (*Pseudogale sepiaria*).—A Japanese shrub 4 ft. high, with trifoliate leaves, fragrant white flowers produced in April and May, and orange-yellow fruits about 1½ in. in diameter.

Culture &c. as above. In the neighbourhood of London this species has proved to be perfectly hardy in ordinary winters in open unprotected situations. The flowers appear before the leaves, the latter not attaining their full size until about the end of June.

XXX. SIMARUBEÆ—Tree of Heaven Order

A natural order containing over 100 species of scentless shrubs or trees, often tall, sometimes herbs, with more or less bitter bark. Leaves alternate, or rarely opposite, pinnate, rarely 1–3-foliolate or simple, leaflets without spots, rarely glandular. Stipules none. Inflorescence usually axillary, paniced or racemose, rarely spicate, or a solitary flower. Flowers diclinous or polygamous, rarely hermaphrodite, regular, usually small. Calyx 3–5-lobed or parted. Petals 3–5, very rarely absent, imbricate or valvate. Disc rarely absent, ringed, cup-shaped or elongated into a gynophore, entire or lobed.

Stamens inserted at the base of the disc, as many, or twice as many, as the petals, very rarely numerous; filaments free, naked, hairy, or scaly at the base. Styles 2-5. Fruit a drupe, capsule, or samara.

AILANTHUS (TREE OF HEAVEN).—

A genus with 3 species of more or less fetid trees having unequally pinnate leaves, and small polygamous flowers in terminal panicles. Calyx equally 5-lobed. Petals 5, spreading. Disc 10-lobed. Stamens 10 (absent in female flowers, 2-3 in hermaphrodite ones). Fruit of 1-5 linear oblong 1-seeded samaras.

A. glandulosa.—A handsome Chinese tree reaching a height of 60 feet in a wild state, with large, pinnate, deciduous leaves 1-3 ft. long, having 9-25 deeply toothed or lobed leaflets. Flowers in August, whitish-green, in large branched terminal, clustered panicles, emitting a disagreeable smell. They are succeeded by oblong purple-brown winged and peculiarly twisted fruits which give the plant a very ornamental appearance.

Culture and Propagation.—This is a fine tree for the lawn or park, and thrives in a light, loamy, well-drained soil. For the first 10 or 12 years it grows rapidly in favourable spots. It is easily increased by slips of the roots or by means of the suckers which are thrown up from the base in great abundance, and sometimes produce simple instead of compound leaves. Seeds are freely produced by the female flowers, and from them plants may also be obtained if sown in cold frames as soon as ripe.

CNEORUM (WIDOW WAIL).—A small genus of ornamental under-shrubs with alternate entire leathery leaves and axillary cymes of small hermaphrodite flowers. Sepals and petals 3-4. Receptacle elongated, columnar, 3-4-ribbed. Stamens 3-4, shorter than the elongated suberect petals, and inserted on the middle of the receptacle. Fruit consists of 1-4 roundish drupe-like cocci.

C. triccoccum.—A smooth S. European shrub 1-2 ft. high, with more or less linear oblong leaves and clusters of yellow bell-shaped flowers borne in the axils during the summer months and replaced in autumn by the 3-lobed fruits.

Culture and Propagation.—This species is fairly hardy in the neighbourhood of London when grown in warm sheltered positions. It grows well in ordinary good garden soil, but prefers a mixture of sandy loam and a little peat. Cuttings of the young and fairly well-ripened shoots will root freely in sandy soil under a handlight, especially if placed in gentle bottom heat. In the colder parts of the kingdom this species would require protection in winter. *C. pulverulentum* from the Canary Islands may be recognised by the greyish powder on its leaves and branches. It is very rarely seen.

XXXI. ILICINEÆ—Holly Order

A natural order of 3 genera and about 150 species, mostly smooth and evergreen trees or shrubs. Leaves usually alternate, without stipules, stalked, simple, leathery, often entire. Flowers small, regular, hermaphrodite, polygamous, dicecious, or unisexual, in axillary or terminal cymes or clusters. Calyx 3-6-partite, imbricate, often persistent. Petals 4-5, rarely more, free or united at the base, hypogynous, deciduous. Stamens usually 4-5, hypogynous, free or slightly adhering to the base of the petals. Fruit a somewhat fleshy drupe, with 3-8 stones or 'pyrenes.'

ILEX (HOLLY).—A genus containing about 145 species of trees or shrubs, with alternate, often shining, entire, toothed or spiny leaves. Peduncles axillary, few-flowered, or often branched. Flowers white, often hermaphrodite. Calyx small, 4-5-cleft. Corolla rotate 4- (rarely 5-6-)

parted. Fruit a globose drupe with 4-8 stones.

I. Aquifolium (Common Holly).—A British and European tree 10-40 ft. high, with ovate or oblong acute, shining, wavy, spiny-toothed, deep green leaves. Flowers in May and June on short

axillary stalks, succeeded by round red berries.

The Holly is at all seasons of the year an ornamental tree, but particularly so in winter when it is covered with its numerous scarlet berries nestling among the dark green, shining foliage. Its value for hedge-making is well known, and in bygone days it was clipped into all kinds of fantastic and unnatural shapes. On the lawn some varieties standing alone are very effective.

Culture and Propagation.—The Hollies thrive in good loamy soil, and are best transplanted early in the autumn, so that a few new roots may be made before the frosts of winter set in.

Plants may be raised from seeds, which should be buried in sand until spring and then sown, in beds or drills, covered with about 1 in. of soil, where they will not get parched. The seedlings should not be touched for 2 years, after which they may be transplanted in autumn, about 1 ft. apart, and remain for another 2 years, and again transplant. The special varieties are usually grafted in March on stocks of the Common Holly raised from seed; or are budded in May with a sprouting bud, or in August with a dormant one. The amateur, however, unless he has much time at his disposal, will leave the propagation of Hollies to the nurseryman, and pay a few pence for well-established specimens.

There are many varieties of *I. Aquifolium*, some with green leaves, some with silver and gold variegation, all more or less worthy of cultivation. Most of them have scarlet berries, but the variety *fructu-albo* has white berries; *fructu-luteo*, yellow berries; *fructu-nigro*, black. In the Kew Handlist of trees and shrubs as many as 53 varieties of the Common Holly are enumerated, and many of them are known under other names as well. The following contain some of the best varieties of the Common Holly arranged according to the colouring of the foliage:—

GREEN-LEAVED HOLLIES.—*Attacledensis*, *angustifolia*, *Beeti*, *ciliata*, *crassifolia*, *donningtonensis*, *ferox* (*Hedgehog Holly*), *Foxi*, *handsworthiana*, *hastata*, *Hendersoni*, *heterophylla*, *Hodginsi*, *latis-sima*, *laurifolia*, *maderensis*, *minorca* (or *balearica*), *monstrosa*, *myrtifolia*, *nobilis*, *oblata*, *ovata*, *scotica*, *serratifolia*, *Shepherdii*, *sinescens*, and *whittingtonensis*.

GOLD-LEAVED HOLLIES.—*Aurantiaca*, *aureo-marginata*, *aureo-picta*, *aureo-pumila*, *brevifolia*, *Cooki*, *ferox aurea*, *laurifolia*, *luteo-maculata*, *myrtifolia aurea*, *obscura*, *pendula aureo-marginata*, *speciosa* (or *Golden Queen*), *tortuosa aureo-picta*, and *Webbiana*.

SILVER-LEAVED HOLLIES.—*Argentea regina*, *argenteo-marginata*, *argentea medio-picta*, *ferox argenteo-marginata*, *handsworthensis argentea*, *Ingrami*, *lucida* (or *Silver Queen*), *pendula albo-picta*.

There are a few other Hollies in cultivation, but few of them equal in beauty or hardness the many forms of our Common Holly. The following are some of the best:—

I. cornuta.—A handsome Chinese Holly with stiffish deep green leaves usually furnished with 3 horn-like spines at the apical end, and often with 2 more at the base, especially when young. The small flowers appear in early summer and are succeeded in favourable seasons by bright red berries about $\frac{3}{8}$ in. in diameter.

Culture &c. as above.

I. crenata.—A pretty compact-growing Japanese Holly with small bluntly ovate crenate leaves with more or less revolute margins. The variety *major* (or *Fortunei*) is a more vigorous-growing plant than the type, and may be recognised by its rounder leaves. The variety *variegata* has the leaves blotched or marbled with dull yellow.

Culture &c. as above.

I. dipyrrena.—A very ornamental tree 12–15 ft. high, native of the Himalayas. The angular shoots are clothed with elliptic-oblong tapering leaves 3–4 in. long with spiny serrate cartilaginous margins. The upper surface is deep almost blackish-green, and is in striking contrast to the bright yellowish-green of the under surface, which is traversed by a prominent whitish-green midrib. The small flowers are succeeded by dark brown 2-seeded berries.

Culture &c. as above. A good lawn or park tree.

I. glabra (*Prinos glaber*).—This is the 'Inkberry' of the United States. It grows 2–3 ft. high, and has smooth ovate lance-shaped leaves, with a few spiny teeth near the apex.

Culture &c. as above. Useful for shrubberies.

I. latifolia.—A handsome Japanese tree about 20 ft. high, with bluntly ovate serrate leaves of a deep shining green above, paler beneath. It makes a good specimen plant on grass land.

Culture &c. as above.

I. opaca.—This ornamental tree is a native of the Eastern United States and reaches a height of 20–40 ft., and may be recognised by its flattish oval leaves, the wavy edges of which are sparingly furnished with spiny teeth.

Culture &c. as above.

Other species of Holly in cultivation, but rarely met with, are *I. ambigua*, *I. Amelanchier*, *I. Cassine*, *I. Dahoon*, *I. decidua*, *I. lævigata*, and *I. verticillata*, all from the United States and N. America; and *I. integra* and *I. rotunda*, natives of China and Japan.

NEMOPANTHES.—A genus containing a single species:—

N. canadensis (*Ilex canadensis*; *Prinos integrifolius*).—This is a smooth-branched shrub about 3 ft. high, with alternate, slenderly stalked, oblong, deciduous, entire or slightly toothed leaves. Flowers small, polygamous, white. Calyx in the male flowers minute, 4–5-toothed; in the female flowers absent. Petals 4–5, distinct, linear, spreading. Stamens 4–5. Fruit a light red drupe with 4 or 5 bony nutlets.

Culture and Propagation.—This species thrives in cold, damp, shady places, and is most readily increased by seeds. These may be sown in cold frames as soon as ripe, and the young plants treated in the same way as recommended for Hollies above.

XXXII. CELASTRINEÆ—Spindle Tree Order

An order of small shrubs or trees sometimes spinescent or climbing. Leaves opposite and alternate, often leathery, always simple, sometimes lobed. Stipules minute when present. Flowers very small, greenish or white, often hermaphrodite. Calyx 4–5-lobed or parted. Petals 4–5, imbricate. Stamens 3–5 (very rarely 2–10). Fruit a capsular berry, drupe, or samara.

EUONYMUS (SPINDLE TREE).—A genus with about 40 species of erect or rarely climbing, usually smooth, evergreen or deciduous trees or shrubs, with opposite, stalked, entire or toothed leaves. Calyx, petals, and stamens have the characters of the order. Fruit a 3–5-celled, angled or winged, leathery, often warted capsule. Seeds enclosed in an aril.

Culture and Propagation.—The green, and variegated green and gold and silver Spindle Trees are familiar objects in British gardens. They all grow freely in any kind of soil. I have seen some small plants send their roots through the chinks of a wooden box into a gravel path, and grow into fine bushes, with the box still adhering to the base. For hiding old walls, fences, or unsightly parts of the garden, the Spindle Trees are very useful. They are easily increased by inserting the ripened tips of the branches about 3 in. long into a fine sandy loam in autumn, keeping them damp and fresh with a frequent spraying overhead. To obtain bushy specimens, the tips of the leading shoots must be pinched out. This will induce the development of side

branches, the tips of which may likewise be pinched out if a still more bushy habit is required.

E. americanus (*Burning Bush*; *Strawberry Bush*).—A deciduous N. American shrub 2–6 ft. high, with smooth, 4-angled branches, and ovate oblong-lance-shaped, serrate leaves, almost sessile. Flowers in June, greenish-purple. Fruit scarlet. The variety *obovatus* is chiefly distinguished by having obovate leaves.

Culture &c. as above.

E. atropurpureus (*Waahoo*).—A smooth-branched N. American species 6–14 ft. high, with ovate-oblong, pointed, serrate, stalked leaves, and dark purple flowers in June.

Culture &c. as above.

E. europæus (*Common Spindle Tree*). A smooth, fetid, native deciduous shrub, 5–20 ft. high, with ovate-lance-shaped, finely serrate leaves, and small greenish-white flowers in May, followed by an abundance of bright pink fruits, which open when ripe and reveal the orange-coloured aril. There is a white-fruited variety, one with scarlet leaves in autumn,

and *nanus* or *pumilus*, a dwarf form, rarely exceeding 2 ft. high. Other forms are *atropurpureus*, *aucubæfolius*, *foliis argenteo-variegatis*, and *foliis aureo-variegatis*. The Common Spindle Tree is much used as a stock for grafting the choicer varieties. Some of its forms are handsome objects in autumn owing to the brilliant colouring of the foliage.

Culture &c. as above.

E. fimbriatus.—A distinct evergreen shrub, about 12 ft. high, native of Japan, India &c. Branches round, smooth, with ovate-pointed leaves fringed with long, parallel, serrated teeth. There are varieties with variegated leaves but somewhat tender.

Culture and Propagation.—This species is usually grown in greenhouses, as it is usually killed by a few degrees of frost if grown in the open air. It is suitable for the open air only in the very mildest parts of the kingdom, and may be increased by cuttings of the tops of the shoots like the other species.

E. japonicus.—A handsome evergreen shrub about 20 ft. high, native of Japan, India &c., with oval-oblong, lance-shaped, deep green, leathery, shiny leaves, sharply serrated and pointed. Flowers in April, white.

This species has given rise to a large number of very beautiful varieties with yellow, white, and tinges of red in the foliage, and the names are sufficiently indicative of the colouring, as *albo-marginatus*, *aureo-marginatus*, *latifolius albus*, *latifolius aureus* &c.

Culture &c. as above.

E. latifolius.—A distinct and beautiful deciduous Japanese species 6–8 ft. high, with broad, ovate, finely toothed leaves. Flowers in June, white at first, becoming purple with age. Fruits deep red; arils orange. Thrives in shady places.

Culture &c. as above. This species is perfectly hardy, and in August and September it is singularly attractive on account of its numerous racemes of bright red fruits hanging from thread-like stalks. It is easily increased from seeds.

E. radicans.—This is a distinct Japanese species with small, oblong or rounded, serrate leaves; its sub-variety *variegata* is often used as an edging, but does well trained up against a wall. Other pretty forms are *Silver Gem*, *foliis pictis*, *roseo-*

argenteis, the latter having a decided tinge of red or rose mixed with the green and white.

Culture &c. as above. This species and its varieties make excellent edgings for beds and borders and may be kept within bounds by means of the shears, the use of which in no way detracts from their appearance.

E. verrucosus.—A deciduous European species with warty stems, and somewhat ovate leaves. Flowers in May, greenish-white or yellow.

Culture &c. as above.

PACHYSTIMA.—A small genus of very smooth evergreen shrubs with small, opposite, shortly stalked leathery leaves, minute deciduous stipules, and solitary or clustered greenish flowers in the axils of the leaves. Calyx tube obconical, 4-angled, with 4 rounded lobes. Petals 4, roundish, spreading. Stamens 4, inserted beneath the large flat 4-angled disc. Capsule oblong, flattened, seeds with a whitish membranous aril.

Culture and Propagation.—The plants belonging to this little-known genus will thrive in ordinary good and well-drained garden soil, and may be used in the shrubbery. Cuttings of the more or less ripened shoots will root in autumn in sandy soil if placed under a handlight or in a cold frame, and thus protected during the winter months.

P. Canbyi.—This rather pretty species is a native of the mountains of North Carolina and Virginia, and its somewhat creeping twiggy stems are furnished with oblong linear leaves having slightly toothed margins. The small reddish flowers appear in summer.

Culture &c. as above.

P. Myrsinites (*Myginda myrtifolia*). This shrub is a native of the mountainous regions of N.W. America, and grows 1–2 ft. high. It has small leathery leaves with more or less serrate or entire margins, and greenish flowers, produced in summer.

Culture &c. as above.

CELASTRUS (STAFF VINE).—A genus of often climbing, unarmed shrubs, with alternate, stalked, entire or toothed leaves. Flowers sometimes unisexual. Calyx urn-shaped at the base, 5-cleft. Petals 5, inserted under the disc. Stamens 5, inserted in the sinuses of the cup-

shaped or concave 5-lobed disc. Capsule roundish, globose, or oblong, leathery. Seeds inclosed in an aril.

C. Orica (*Orixa japonica*).—A Japanese shrub 6-9 ft. high, with elliptic or obovate glossy green leaves having entire edges. The small greenish flowers are produced in summer, the males usually being in racemes, the females solitary and long-stalked.

Culture and Propagation.—This species is hardy in the neighbourhood of London, and like the better known *C. scandens* will thrive in ordinary good garden soil in sheltered positions. It may be increased by layers.

C. scandens (*Climbing Waxwork*; *Bitter Sweet*).—A deciduous N. American climber, 12-15 ft. high, with ovate-pointed, serrated leaves 3 in. long, 2 in. broad. Flowers in early summer, pale yellow, in terminal racemes, succeeded by 3-angled, 3-seeded orange berries.

Culture and Propagation.—This species thrives in ordinary soil, and is increased by layering the young shoots in autumn. Seeds may also be sown in cold frames as soon as ripe, and as soon as large enough the following spring they may be moved into a prepared bed of good garden soil outside. For covering arbours

or trellises with its masses of glossy foliage in summer, and bright berries in autumn, it is very effective.

MAYTENUS.—A rather large but not well-known genus of evergreen bushes or shrubs, with alternate and often 2-ranked, stalked, leathery, serrate leaves, and minute deciduous stipules. Flowers small, polygamous, white, yellow, or reddish, borne in the axils of the leaves, either solitary or in clusters or cymes. Calyx 5-cleft. Petals spreading. Stamens 5, inserted beneath the roundish wavy-edged disc. Capsule leathery, 1-3-celled. Seeds with a pulpy aril.

M. chilensis.—A Chilian shrub 6-10 ft. high, with elliptic oblong serrate leaves, tapering at each end. The greenish-yellow flowers appear in early summer and are not particularly attractive.

Culture and Propagation.—This species is probably unknown outside botanic gardens. It grows in ordinary good garden soil in warm and sheltered positions protected from the north and east winds. It may be increased by layering the shoots in late summer or autumn, or by placing cuttings of the ripened shoots in sandy soil under a hand-light in autumn. It is fairly hardy in the neighbourhood of London.

XXXIII. RHAMNÆ—Buckthorn Order

An order of erect or climbing trees or shrubs, often spiny, rarely tendrilled or glandulose, with alternate, simple, usually stipulate leaves, often 3-5-nerved, entire or serrate. Flowers usually hermaphrodite, often in loose or dense axillary cymes. Calyx-tube leathery, 4-5-lobed. Petals 4-5, or none. Stamens 4-5 inserted with the petals in the throat of the calyx. Fruit capsular or drupe-like.

PALIURUS (CHRIST'S THORN).—A genus of sub-erect or decumbent smooth or slightly tomentose shrubs, armed with stipular spines. Calyx-tube 5-cleft, broadly obconical. Petals 5, small, hooded, often deflexed. Disc 5-lobed. Stamens 5, enclosed by the petals or projecting beyond them.

P. aculeatus.—A prickly shrub about 8 ft. high, native of the Mediterranean region. Leaves ovate, serrulate, smooth, 3-nerved, with 2 spines at the base, one erect, the other hooked. Flowers in summer, greenish-yellow. Fruit like a head with a broad-brimmed hat. The

appropriate name of *aculeatus* has now been dropped by botanists, who call this plant *P. australis*, the latter name referring to its habitat in S. Europe.

Culture and Propagation.—This species, as well as *Zizyphus spina-Christi*, is supposed to have supplied the crown of thorns placed on our Lord's head. It grows freely in ordinary soil, and may be increased by layers, cuttings of the roots, or seeds in late summer or autumn. The root cuttings and seeds are best treated under protection in cold frames or under handlights. In very severe winters the tips of the branches are likely to suffer.

BERCHEMIA.—This genus contains about 10 species of erect or often high-climbing shrubs, having alternate stalked leathery, feather-veined leaves, and small deciduous stipules. The small flowers (which are sometimes polygamous, although usually hermaphrodite) are borne either singly or in clusters in the axils of the upper leaves, or in panicles at the end of the shoots. Calyx 5-cleft with a hemispherical or top-shaped tube. Petals 5, obovate or lance-shaped, hooded. Stamens 5. Fruit a blackish or purple drupe.

B. volubilis (*Rhamnus scandens*; *R. volubilis*).—A rather pretty deciduous climber native of the Southern United States. Its smooth branches are furnished with slightly wavy oval leaves having a short sharp point. The small greenish-white flowers are borne in summer in the axils of the leaves and also at the end of the shoots, and are succeeded in autumn by oblong violet or purple fruits.

Culture and Propagation.—This species is hardy in most parts of the kingdom, and will grow in ordinary good garden soil. It may be utilised for training over tree stumps, bowers, trellises &c. in the rougher parts of the garden. It is increased by inserting cuttings of the ripened shoots, and also of the roots, in sandy soil under a handlight in autumn, or in gentle bottom heat. The branches may also be layered during the late summer and autumn.

RHAMNUS (BUCKTHORN).—A genus with about 60 species of evergreen or deciduous trees or shrubs. Flowers in axillary cymes, often unisexual. Calyx-tube urn-shaped, 5-cleft. Petals 4-5, or none. Stamens 4-5, with very short filaments. Fruit a berry-like drupe, oblong or globose.

Culture and Propagation.—The Buckthorns grow well in ordinary garden soil, and may be increased by layers in autumn or cuttings of the ripened shoots inserted in sandy soil under a handlight or in a cold frame. Seeds of many of the Buckthorns are ripened freely in the British Islands, and fresh plants may be obtained by sowing these as soon as ripe, or in spring in cold frames.

R. Alaternus.—A native of the southern coasts of Europe, about 20 ft. high, with ovate-elliptic or lance-shaped, leathery, serrated leaves. Flowers from

April to June, green, diœcious; petals absent. There is a variegated form having the leaves broadly edged with silvery white, and also one called *latifolius* with broader leaves than the type.

Culture &c. as above. Ripens seeds freely.

R. alpinus.—A European shrub, 4 ft. high, with oval lance-shaped, crenate-serrate leaves with parallel veins. Flowers in early summer, greenish, diœcious: female ones with 4-cleft stigmas. The variety *grandifolius* is an improved form.

Culture &c. as above.

R. californicus (*R. oleifolius*).—An unarmed evergreen Californian shrub 6-12 ft. high, with leathery, elliptic oblong, entire leaves 2 in. long. Flowers in May, greenish, with 5 stamens.

Culture &c. as above. Ripens seeds freely.

R. catharticus (*Common Buckthorn*).—A British shrub 5-10 ft. high, with ovate, acutely serrated leaves. Flowers from May to July, greenish. Fruit black, $\frac{1}{4}$ in. in diameter.

Culture &c. as above. Ripens seeds freely.

R. croceus.—A spiny, evergreen shrub 4 ft. high, native of California. Leaves leathery, roundish obovate, about $\frac{1}{2}$ in. long, of a bright yellowish-brown beneath when dry. Flowers in May, greenish, with 5 stamens; petals absent. Fruit greenish or yellowish.

Culture &c. as above. This species is rarely seen.

R. davuricus (*R. utilis*).—A spiny Chinese shrub, 15-20 ft. high, with obovate pointed or narrowly elliptic lance-shaped leaves in clusters at the ends of the branchlets. Flowers in May, greenish-yellow.

Culture &c. as above.

R. Frangula (*Berry-bearing Alder*; *Black Dogwood*).—A British shrub 5-10 ft. high, with obovate entire leaves, and awl-shaped stipules. Flowers in early summer, greenish-white, followed by black fruits $\frac{1}{4}$ in. in diameter. The wood is used for gunpowder. There are several varieties of this species, among which may be noted *asplenifolius*, *aureo-variegatus*, *angustifolius*, and *latifolius*.

Culture &c. as above. Ripens seeds freely.

R. latifolius.—A shrub about 5 ft. high, native of the Azores. Leaves elliptic, pointed, entire, with 12-15 nerves. Flowers in July, greenish, hermaphrodite; stigma slightly 3-cleft.

Culture &c. as above.

R. libanoticus.—An unarmed shrub 6 ft. high, native of Asia Minor, with whitish bark. Leaves shortly stalked, ovate, or oblong blunt, rounded at the base, finely toothed on the edge, becoming bronzy purple in autumn. Flowers in May, yellowish.

Culture &c. as above. Ripens seeds freely.

R. robustus.—A vigorous tree about 20 ft. high, with dark green, leathery leaves 7-8 in. long, over 3 in. broad, broadly ovate lance-shaped. Flowers in May, green, succeeded by black, globose fruits, $\frac{1}{2}$ in. in diameter.

Culture &c. as above.

CEANOTHUS.—A genus of about 30 species of evergreen smooth or downy shrubs, with alternate, rarely opposite, stalked, leathery, entire leaves. Stipules minute, caducous. Flowers hermaphrodite, small, numerous, in terminal cymose clusters or panicles. Calyx-tube turbinate or hemispherical, 5-cleft. Petals 5, inserted beneath the thickened disc and narrowed into a stalk or claw at the base, the broader apical portion being hooded. Stamens 5, longer than the petals. Fruit a 3-lobed drupe.

Culture and Propagation.—These ornamental plants thrive in a light, rich, well-drained soil, and do well in almost any position. They are chiefly suitable for walls, where they flower profusely, but some kinds such as *C. americanus* and *C. azureus* make beautiful bushes in warm and open situations, sheltered from the north and east winds. The spring or early summer flowering varieties should be pruned after the period of blooming is over, leaving 2 or 3 eyes of the previous year's growth to produce the flowering trusses for the following year. The later flowering kinds may be pruned in a similar way, or early in the year before growth begins.

They may be readily increased by layers; or from seeds sown in autumn in a cold frame in sandy soil. Cuttings of the ripened shoots will also root freely in sandy soil under handlights in late summer and autumn.

C. americanus (*New Jersey Tea*).—A N. American shrub about 4 ft. high, with ovate pointed, serrated leaves 2-3 in. long, downy beneath and distinctly 3-nerved. Flowers from June to September, white, in long axillary clusters near the ends of the shoots.

Culture &c. as above. This species may be grown either on a wall or as a bush according to the mildness or otherwise of the locality. The popular name is probably due to the fact that its leaves were brewed into tea during the civil war by the American soldiers.

C. azureus (*C. bicolor*; *C. cæruleus*).—A pretty Mexican shrub 3-5 ft. high, with blunt ovate-oblong, acutely serrated leaves, smooth above, downy beneath. Flowers in April and May, pale blue, borne in long dense racemes. *Gloire de Versailles, Arnoldi, Bertirii, Lucie Moser, Theodor Frœbel, President Reveil, Virginal, Sceptre d'Azur, Ceres, Carmen &c.* are fine varieties raised by crossing *C. azureus* and *C. americanus*. The hybrids are far superior to their parents and there is a greater range of colouring in their flower trusses, varying from blue to white and pale rose. The flowering period of many of them also extends from June to September, some being earlier or later than others.

Culture &c. as above.

C. collinus.—A North American species about 1 ft. high, with ovate or elliptic, somewhat clammy leaves, and trusses of white flowers in summer.

Culture &c. as above. Rarely seen.

C. cuneatus (*C. verrucosus*).—A Californian shrub 4 ft. high, with wedge-shaped, obovate or oblong usually entire leaves, which are opposite, instead of alternate, as in most of the species. Flowers in April, pale blue, sometimes white.

Culture &c. as above.

C. dentatus (*C. Lobbianus*).—A pretty evergreen 4-6 ft. high, native of California. Leaves clustered, obovate or oblong elliptic, acute, waved on the edges. Flowers in early summer, blue.

Culture &c. as above.

C. divaricatus.—A dense-growing N. American shrub 3-10 ft. high, with spinose straggling branches, and oblong ovate leaves, rounded at the base, blunt or acute at the apex, and with a very glossy

green surface. Flowers in May and June, nearly white or very pale blue.

Culture &c. as above. This species requires wall protection.

C. floribundus.—A Californian shrub with small, oblong acute, serrulate, shining green leaves. Flowers in June, brilliant blue, crowded in globular heads.

Culture &c. as above, p. 305.

C. integerrimus.—A shrub 3-6 ft. high, native of California. Leaves ovate-oblong entire or slightly glandular, with entire not toothed edges. Flowers in June, usually white, sometimes tinted with blue, and borne in large panicles at the ends of the shoots.

Culture &c. as above. Best grown on a wall.

C. microphyllus.—A somewhat decumbent N. American species 2 ft. high, with small, oblong, blunt, entire leaves. Flowers in May and June, white.

Culture &c. as above. Rarely seen.

C. ovatus (*C. ovalis*).—A native of Eastern N. America, closely related to *C. americanus*. It has narrow oval leaves 1-2 in. long, smooth above, and toothed on the margins. Flowers from June to September, white.

Culture &c. as above, p. 305.

C. papillosus.—A hairy Californian shrub 6-10 ft. high. Leaves narrowly oblong, serrulate with numerous wart-like excrescences on the dark green shining upper surface. Flowers in May and June, blue, in dense clusters.

Culture &c. as above. Best on a wall.

C. rigidus.—Native of California 5-8 ft. high. Leaves broadly wedge-shaped or obovate, often emarginate, slightly toothed and, like *C. cuneatus*, opposite instead of alternate, on the woolly or downy branches. Flowers in April and May, deep purple, in long terminal spikes.

Culture &c. as above. Best on a wall.

C. thyrsoiflorus (*C. elegans*).—An elegant species, native of California, where it is said to grow into a fine tree about 25 ft. high. The distinctly angled branches are clothed with smooth glossy green toothed leaves 1-2 in. long, and the brilliant blue flowers are borne in dense clusters from June to September.

Culture &c. as above. This species requires the protection of a wall, although it may succeed as a bush or small tree in

the open in the mildest parts of the south and west.

C. veitchianus.—A fine Californian shrub, with thick, small, oblong-obovate glandular serrulate leaves with a smooth and shining upper surface. Flowers in early summer, rich deep blue, in dense clusters at the ends of the leafy branches.

Culture &c. as above. Best on a wall.

C. velutinus.—A pretty Californian species having large ovate leaves, deep green above, whitish beneath. The whitish flowers are borne in dense clusters during the summer months.

Culture &c. as above. This seems to be more tender than any of the other species described above. It must therefore be protected by a warm wall, and may prove quite hardy in the south and west in the most favoured localities.

COLLETIA.—A genus of curious and remarkable shrubs often without leaves, and having spreading opposite and 2-ranked branches with spiny shoots. Leaves when present very small, entire, opposite. Flowers clustered or solitary beneath the spines. Calyx membranous bell-shaped or tubular with a 4-5-cleft limb. Petals none, or 4-6 inserted at the mouth of the calyx. Stamens 4-6, inserted with the petals. Fruit a drupe or capsule.

C. cruciata (*C. bictoniensis*).—A very remarkable looking shrub 4-10 ft. high, native of Uruguay, having the stems furnished with pairs of flat triangular woody spines, often $1\frac{1}{2}$ in. across at the base, each pair of spines being usually at right angles to the next pair, thus giving a cross-like arrangement. As a rule the small ovate toothed leaves appear only on the young branches. The small creamy or yellowish-white flowers (which have no petals) appear in autumn, either singly or in clusters, on the under side of the flat spines, and attract attention when in great abundance. There are various forms of this ferocious looking shrub known, and they were at one time regarded as distinct species. The best known perhaps is *C. spinosa* (or *C. horrida*), which may be recognised by having long slender stiff and sharply pointed spines over 1 in. long, and only slightly flattened. Occasionally both forms—*C. cruciata* with broad flattish spines, and *C. spinosa* with long slender spines—are found on the same plant. Other variations have been recognised and are represented by such names

as *armata*, *ferox*, *polyacantha*, *spinossissima*, and *valdiviana*, but they have all originated from the same species.

Culture and Propagation.—Although when first introduced to cultivation *C. cruciata* was grown in hothouses, it has since proved to be practically hardy in ordinary winters in the neighbourhood of London, and has not been injured by 10° of frost. It is, however, wise to grow it in sunny sheltered situations, and in good well-drained garden soil. The plants may be increased by inserting cuttings of the more or less ripened shoots in sandy soil under a handlight or on a gentle hotbed.

DISCARIA.—A genus containing about a dozen species of much-branched shrubs closely related to the Colletias, having often spiny branches, small opposite leathery leaves in the axils of which the small flowers are produced. Calyx more or less tubular or bell-shaped, with 4-5 recurved lobes. Petals none, or 4-5, hooded, and inserted in the mouth of the calyx. Stamens 4-5, inserted with the petals. Fruit a dry leathery 3-lobed drupe or capsule.

D. serratifolia (*Colletia serratifolia*). A graceful Chilean shrub 10-12 ft. high,

having long slender drooping shoots, clothed with dark green and very glossy ovate-oblong serrate leaves $\frac{1}{2}$ -1 in. long, and furnished with a pair of stiffish slender spines at each joint. The small greenish-white flowers are sweetly fragrant, and produced in dense clusters during June and July, giving the plants an attractive appearance.

This is the best known and most ornamental species in cultivation, but to it may be added *D. longispina* (also known as *Colletia longispina*) from Uruguay. This has rather longer spines than *D. serratifolia*, and masses of small yellowish-white blossoms. *D. Toumatou* is another species from New Zealand. It grows 2-6 ft. high, having the stems armed with sharp spines 1-2 in. long, and clusters of small white flowers.

Culture and Propagation.—The Discarias require to be grown in warm sheltered situations, and will flourish under the same conditions as the Colletias. Ordinary good and well-drained garden soil suits them well, and new plants may be obtained by means of cuttings of the more or less ripened shoots inserted in sandy soil under a handlight or in a hotbed.

XXXIV. AMPELIDEÆ—Vine Order

An order containing about 250 species of evergreen or deciduous climbing shrubs often with copious watery juice, and tendrils. Stems knotted or jointed, roundish; angled, or compressed. Leaves alternate, stalked, simple or digitately 3-5-foliolate, or pedate. Flowers regular, hermaphrodite or unisexual, small, in cymes or panicles, opposite the leaves, rarely axillary. Calyx small, entire, or 4-5-toothed or lobed. Petals 4-5, free or variously united. Stamens 4-5, opposite the petals. Style short, conical, awl-shaped or none; stigma capitate or disc-like, somewhat lobed. Fruit a berry, often watery as in the well-known Grape.

VITIS (including AMPELOPSIS).—A genus with about 230 species having the botanical characters as described for the order above.

Culture and Propagation.—The Vines are all beautiful climbing shrubs, the foliage of which gives wonderful autumn tints, and may be utilised in a variety of ways—for covering naked walls, on trellises, over boulders of rock-work, up poles, over arbours &c. They thrive in deep, rich, loamy soil, and being gross

feeders should have the soil well manured or mulched every year in late autumn or during the winter months.

Vines are perhaps most graceful when grown in parts of the garden where they may spread forth their graceful and leafy branches at will. It is, however, more or less necessary according to circumstances as regards space, or the vigour of any particular variety, that the plants should be pruned or thinned out occasionally. This operation is best done at the begin-

ning of the year while the buds are still dormant, cutting back the shoots almost close to the main stem, so as to leave one or two buds to develop branches wherever required.

They may be increased by cuttings of the ripened wood inserted in pots in a close frame in January and February, or many of them—like the Virginian Creeper (*Vitis quinquefolia*) will root readily out of doors if cuttings about 4 in. long are inserted in the autumn in a shady border. Each joint containing a good plump and well-ripened bud will make a new plant if inserted in gentle heat in the early part of the year. When the cuttings are well rooted they may be potted up singly into small pots, and kept in a close warm frame or greenhouse for some time until well established. Frequent sprinklings overhead with tepid water will be very beneficial, as the young plants do not like a dry atmosphere.

V. aconitifolia (*Ampelopsis triloba*; *A. lucida*; *A. tripartita*; *V. dissecta*).—A slender, elegant and free-growing Chinese species, with long reddish branches, and leaves deeply cut and lobed like those of the Monkshood. There are two or three forms in cultivation.

Culture &c. as above.

V. acuminata.—A native of Eastern Asia having narrow ovate entire leaves rounded or slightly heart-shaped at the base, gradually tapering to a sharp point and scarcely toothed on the edges. The upper surface is quite smooth, but the under one is covered with a glaucous white down. In autumn the plants are rendered ornamental by the long narrow bunches of large black Grapes.

Culture &c. as above.

V. æstivalis (*American Summer Grape*).—A North American climber 20 ft. long, with simple, rounded, heart-shaped leaves, often variously lobed, woolly beneath, rather smooth when old. Flowers in May and June, scented like Mignonette. Fruit black with a bloom, pleasant-tasting, ripe in October, and resembling the fruits of the Black Currant in appearance.

Culture &c. as above.

V. amurensis.—A vigorous grower native of N. China, with the young

stems and leaf stalks tinged with purple, but not particularly coloured in autumn.

Culture &c. as above.

V. arborea.—A beautiful N. American species distinguished by its twice pinnate leaves, the numerous leaflets being small and deeply toothed. It is of shorter and more bushy growth than the other species. Flowers in June, green, small, succeeded by globose berries. This species is also known as *V. bipinnata*.

Culture &c. as above.

V. arizonica.—A native of Arizona, with a beautiful habit and very small leaves. It looks well grown as a bush or over a short stump.

Culture &c. as above.

V. Berlandieri (*V. monticola*).—This hardy Vine is a native of Texas and New Mexico, and is remarkable for having 5-angled stems covered with a crispy and flaky down. The roundish heart-shaped leaves are more or less 3-lobed and toothed, and in autumn clusters of blackish-violet berries are borne.

Culture &c. as above.

V. californica.—A beautiful Californian Vine remarkable for the deep crimson colouring of its roundish downy leaves in autumn. It is a vigorous grower, and becomes more highly coloured in hot dry seasons. It likes plenty of moisture at the root in summer and repays for being grown in deep rich soil.

Culture &c. as above.

V. capreolata.—A native of the Temperate Himalayas, with 5-foliolate leaves; leaflets more or less ovate-lance-shaped, acute, 2-3 in. long. Fruit black, globose, about the size of a Currant.

Culture &c. as above. This species may not be quite hardy in northern parts. It is best on a south wall.

V. Coignetia.—A beautiful Japanese Vine, with large, heart-shaped, irregularly toothed leaves 6-10 in. across, turning a glorious crimson in autumn and having the under surface more or less densely covered with a reddish woolly down.

Culture &c. as above. It is fairly easily raised from imported seeds, but some little difficulty has been experienced in obtaining plants in the usual way from cuttings, although it grafts readily on several of the American species.

V. cordifolia (*Chicken, Frost, or Winter Grape*).—A vigorous N. American climber 12 ft. long, with thin, 3-lobed, heart-shaped leaves, 3-6 in. wide, sharply and coarsely toothed. Flowers in early summer, sweet-scented. Berries blue or black, with a 'bloom,' sharp-tasting, ripening after frost. *Riparia* is a form with broader cut-lobed leaves; and *pal-mata* is a sub-variety with the leaf stalks and branches frequently red in colour.

Culture &c. as above, p. 307.

V. davidiana (*Cissus davidiana; C. platanifolia; C. rubricaulis; Spinovitis Davidi*).—A vigorous Chinese climber with broadly 5-lobed sharply toothed leaves on long red stalks. Fruits violet in colour, not eatable. This species is closely related to *V. Romaneti* and varies a good deal in character if the plants are raised from seeds.

Culture &c. as above, p. 307.

V. ficifolia.—A distinct species, native of China and Japan, and remarkable chiefly for its small roundish lobed leaves somewhat like those of the Common Fig.

Culture &c. as above, p. 307.

V. heterophylla humulifolia (*Hop-leaved Vine*).—A splendid Chinese and Japanese climber with 3-5-lobed, sharply serrate leaves, dark green and wrinkled above, pale beneath with downy veins, on slender red stalks. One of the features of this plant is its beautiful turquoise-blue berries produced in great abundance, and speckled with black. The variegated form is very desirable, the leaves being beautifully marbled with white or pale rose on a greenish ground.

Culture &c. as above. A warm sunny situation suits these plants best.

V. inconstans (*Ampelopsis Veitchi; A. tricuspidata*).—One of the most beautiful and useful of Vines, best known in gardens under its synonyms. The name here adopted is, however, descriptive of the varying and inconstant shape of the leaves, which from being almost entire in a young state change to roundish heart-shaped with 3 wedge-shaped tailed lobes and coarsely toothed edges in the older and larger ones. In some of the best forms the leaves assume in autumn beautiful shades of purplish-red and crimson, while others are of a mellow brown. It is a native of Japan.

Culture and Propagation.—This plant grows freely in good soil, and in a year or

two will completely cover a wall or the end or sides of a house, the slender, wiry branches clinging to the stones or bricks by means of numerous suckered tendrils.

It may be easily increased from cuttings of the ripe wood cut to a single 'eye' or joint, and inserted in light sandy soil in gentle bottom heat any time from January to the middle of March.

V. japonica (*Cissus japonica*).—A vigorous Japanese species having leaves divided into 5 stalked roundish oval, toothed or pointed leaflets. There is a variety called *marmorata* with broad yellow blotches on the leaves, and another named *crassifolia* which has large and thick leathery 3-lobed leaves, the upper surface of which is bright shining green, and the under surface is covered with a cobwebby down.

Culture &c. as above. This species is somewhat tender except in the mildest parts.

V. Labrusca (*American Plum Grape; Isabella Grape; Northern Fox Grape*).—

A very attractive North American species with large, roundish heart-shaped, variously lobed leaves, rusty woolly beneath. The flowers are scented like Mignonette, followed by large dark purple or amber-coloured berries, with a tough, musky pulp, ripe in September or October.

Culture &c. as above.

V. lanata.—A beautiful Himalayan species with heart-shaped, ovate, shortly pointed leaves 3-6 in. long, 2-3 in. broad, softly downy, occasionally woolly beneath or nearly glabrous, assuming a beautiful scarlet colour in autumn. The green flowers in May are succeeded by round, purple fruits in autumn.

Culture &c. as above.

V. quinquefolia (*Ampelopsis hederacea; A. quinquefolia*).—*Virginian Creeper*.—A well-known N. American climber with palmate leaves cut into 3-5 leaflets, oblong pointed, toothed, assuming in autumn various shades of crimson, scarlet and purple.

A most luxuriant grower, and useful for covering walls, arbours, trellises, old tree trunks, verandahs &c. There are a few varieties, such as *incisa*, with more deeply cut leaves; *hirsuta*, downy on both surfaces; *muralis*, which, unlike the other forms, has the power of attaching

itself to walls by means of suckered tendrils, like *V. inconstans*.

Culture &c. as above.

V. reniformis violacea.—A distinct Chinese Vine with long slender stems and large roundish kidney-shaped leaves with crenulate margins, deep green above, paler beneath and strongly veined, the veins and stalks being clothed with cottony hairs. The male and female flowers are borne on separate plants, the male ones being in small panicles on slender deep red stalks.

Culture &c. as above.

V. Romaneti.—A vigorous and distinct Chinese species with large heart-shaped, toothed leaves, the stalks of which, as well as the branches, are covered with stout hairs or bristles. The male and female flowers are borne on separate plants in compact clusters.

Culture &c. as above.

V. serianiaefolia (*Ampelopsis serianiaefolia*; *A. tuberosa*; *Cissus viticifolia*).—A tuberous-rooted Japanese species, with green palmately 3-5-parted leaves; leaflets obovate acute incised-toothed or somewhat lobed; rachis articulately winged.

Culture &c. as above.

V. striata.—A beautiful evergreen climber, native of S. Brazil and Uruguay, with rather thick, digitate, dark-green leaves; leaflets unstalked, oblanceolate, serrate, wedge-shaped at the base. Fruit reddish, about the size of small peas. It is called the Ivy of Uruguay, where in the woods it is one of the most beautiful climbers, covering the bushes with red berries in winter.

Culture &c. as above. Although from rather warm regions, this species is hardy in warm sheltered places in the neighbourhood of London.

V. Thunbergi.—A vigorous grower with large leaves 9 in. across, slightly lobed and coarsely toothed, like those of *V. Coccinea*, covered with a rusty down beneath. Stems and leaf stalks purplish.

Culture &c. as above.

V. vinifera (*Common Grape Vine*).—This native of S. Europe is well known, both as a hardy climber, and as the parent of the varieties grown in hothouses for their luscious fruits. Leaves lobed, sinuately toothed, smooth or downy. Fruit purple, greenish-white or green, watery or fleshy, sweet, musky or sour to the taste. There are several distinct varieties, among which may be mentioned *purpurea*, with purple foliage in autumn; *laciniosa* or *apiifolia* is the Parsley-leaved Vine with leaves deeply cut into several deeply lobed leaflets. The *Miller's Grape* has small leaves covered with white down, as if slightly dusted with flour; and the *Teinturier Grape* has beautiful claret-coloured leaves in autumn. *Amurensis* is a variety with entire 3-5-lobed leaves, woolly on both sides when young.

Culture &c. as above. The cultivation of the Grape Vine for fruit is dealt with at p. 1097.

V. vulpina (*Southern Fox Grape*; *Bullace*; *Muscadine*).—A distinct and handsome N. American species, with rounded, usually smooth and shiny green leaves, coarsely toothed, rarely lobed, 2-3 in. across. Fruits purplish, without bloom, musky flavoured, about $\frac{3}{4}$ in. in diameter, ripe early in autumn. The bark of this species does not peel off like others, and the branchlets are minutely warty.

Culture &c. as above.

XXXV. SAPINDACEÆ—Horse Chestnut Order

A very large order (600 or 700 species) of trees, shrubs or undershrubs, rarely herbs, with alternate or opposite, simple or compound leaves, often evergreen, and regular or irregular, usually polygamous-dioecious flowers. Sepals 4-5, very rarely none or more, free, or united, often unequal. Petals none, or 3-5, very rarely more, equal or unequal, the upper one sometimes smaller or deficient. Stamens 8, rarely 5-10 (very rarely 2, 4, or 12 or more), very often hypogynous and inserted in the disc. Fruit capsular, indehiscent, drupe-like, berry-like, or leathery, entire or lobed, or composed of 2 or 3 samaras.

KÆLREUTERIA.—The characters of this genus are described below under

K. paniculata, which until recently was the only species known.

K. bipinnata.—A recently introduced Chinese tree with twice pinnate leaves 2 ft. or more long and nearly as broad, each of the pinnae having 9-10 ovate acute toothed leaflets. The bright yellow flowers with a purple blotch at the base of the petals are like those of *K. paniculata*, and are borne in summer in large panicles. The broadly elliptic fruits about 2½ in. long are purple when ripe.

Culture &c. as for *K. paniculata*.

K. paniculata.—A handsome tree, 10-15 ft. high, native of N. China, with alternate, deciduous, oddly pinnate leaves, composed of 7-9 pairs of deeply toothed leaflets, rich yellow in autumn or varying to bronze and purple. Flowers in summer, irregular, polygamous, yellow, in large terminal panicles about 2-3 ft. long. Calyx 5-parted, equal, with valvate sepals. Petals 3-4, clawed, with 2 scales at the base, the seat of the fifth petal vacant. Stamens 5-8, bent down, with free hairy filaments. Fruit a large vesicular, inflated, 3-lobed capsule, very conspicuous in autumn, but only produced in quantities during hot and favourable seasons.

Culture and Propagation.—This is an excellent plant for groups, and will thrive in any good soil, in a warm, sheltered position. It may be increased by cuttings of the young wood in spring, inserted in light sandy soil under hand-lights or bell-glasses in gentle heat, or by layers in early autumn.

ÆSCULUS (including Pavia)
(HORSE CHESTNUT; BUCK EYE).—A genus of about 14 species of beautiful flowering, deciduous trees, with opposite, exstipulate, digitate leaves, composed of 5-9 serrated leaflets. Flowers polygamous, irregular. Calyx bell-shaped or tubular, 5-cleft, with unequal, imbricate lobes. Petals 4-5, unequal, clawed. Stamens 5-8, free, inserted in the disc. Fruit a leathery capsule, smooth or prickly, 3-lobed, or almost globose. Seeds large, like those of the Sweet Chestnut in appearance. The genus *Pavia*, which is included here, is chiefly distinguished by having no prickles on the fruits.

Culture and Propagation.—The Horse Chestnut and Buck Eyes are noble ornamental trees, which thrive in almost any soil, but preferably loam. The seeds germinate freely, but some of the rarer kinds are grafted or budded on stocks of

the common Horse Chestnut (*Æ. Hippocastanum*).

As solitary specimens in parks and large gardens, or as planted in avenues, the Horse Chestnuts must be regarded as some of the finest sights on the landscape. They not only flower profusely, but they cast a deep and refreshing shade during the hot summer days. The specimens in Bushey Park near Hampton Court are famous for their beauty, and thousands go purposely to see them in blossom every year. Along the banks of the Thames from Kew to Richmond and also in Kew Gardens there are many noble specimens.

Æ. californica.—A handsome Californian tree, often 40 ft. high in its native habitat, but much smaller in this country. Leaves with smooth oblong-lanceolate, serrulate leaflets. Flowers in May, white or pale rose, highly fragrant, borne in great profusion.

Culture &c. as above.

Æ. carnea (*Æ. rubicunda*; *Æ. cocinea*). A distinct and beautiful North American tree 20 ft. high, with 5-7 obovate-wedge-shaped, serrated leaflets composing the leaves. Flowers in June, scarlet, in terminal clusters; petals 4; stamens 8.

Culture &c. as above.

Æ. chinensis.—An ornamental tree, native of the mountains near Peking. Its large palmate leaves are composed of oblanceolate acute leaflets 6-8 in. long, with serrate or crenate margins, while the leaf stalks and also the flower stalks are covered with fine hairs. The creamy white flowers are borne in pyramidal clusters somewhat later in the season than those of the common Horse Chestnut, but are not so large or striking in appearance as in that species.

Culture &c. as above.

Æ. flava (*Æ. neglecta*).—*Sweet Buck Eye*.—A beautiful N. American tree 20-25 ft. high, with leaves on downy stalks, and composed of 5-7 elliptic oblong leaflets, downy beneath. Flowers in May, pale yellow, with a tubular, 4-petalled corolla. Country lads are fond of sucking the nectar from the flowers of this species. The variety *purpurascens* (also known as *Pavia discolor*; *P. hybrida*; and *Æ. discolor*) has yellow flowers, tinged with red or purple.

Culture &c. as above.

Æ. glabra (*Æ. ohioensis*; *Æ. pallida*). A North American species, 20 ft. high, with very smooth leaves cut into 5 leaflets. Flowers in June, greenish-yellow; corolla with 4 spreading, clawed petals, shorter than the stamens.

Culture &c. as above.

Æ. Hippocastanum (*Common Horse Chestnut*).—This huge, well-known tree from the mountainous regions of S. Eastern Europe is probably the noblest looking flowering tree in the British Islands. Its leaves are divided into 7-8 obovate-wedge-shaped, acute, coarsely toothed leaflets 6-9 in. long. According to locality the beautiful white flowers tinged and speckled with red are produced in more or less erect pyramidal racemes, about 1 ft. long, from Easter to Whitsuntide, from the end of almost every branch. There are a few varieties known. One *flore pleno* has double or semi-double flowers; *foliis aureis variegatis* has the leaves blotched with yellow; and *laciniata* has the leaves more or less finely cut and lobed.

On the Continent the seeds of the Horse Chestnut are used as food for cattle, sheep, pigs and poultry, and are said to improve the quantity and flavour of milk in cows.

Culture &c. as above. Easily raised from seeds sown in autumn. Owing to the shade of this tree, and the horizontal spreading of its branches, little else will grow beneath it except Ivy.

Æ. indica.—A handsome tree native of N. India, with very large smooth leaves, having 7-9 lance-shaped, serrate, stalked leaflets. Flowers in May in terminal clusters; lower petals white tinged with red, upper ones yellow and edged with white.

Culture &c. as above.

Æ. parviflora (*Æ. macrostachya*; *Pavia macrostachya*).—A dwarf North American tree 3-9 ft. high, with leaves composed of 5-7 oval-obovate leaflets, woolly beneath. Flowers from April to July, white, in long racemes. Stamens 6-7, three times longer than the corolla.

Culture &c. as above.

Æ. Pavia (*Pavia rubra*).—*Red Buck-eye*.—A N. American tree 10-15 ft. high, with leaves composed of 5 elliptic oblong acute leaflets, slightly bearded in the axils of the nerves beneath. Flowers in

May, bright red, in large loose clusters. The variety *humilis* grows only about 6 ft. high; *laciniata* has deeply cut leaflets; *pendula* has drooping branches; *atrosanguinea* and *Whitleyana* have more brilliant flowers than the type.

Culture &c. as above.

UNGNADIA.—A genus represented only by the following species:—

U. speciosa.—An ornamental shrub or small tree, native of Texas, having alternate oddly pinnate leaves composed of 3-7 pairs of serrate ovate lance-shaped leaflets. The irregular polygamous flowers appear in summer in lateral clusters and are of a pleasing pinky shade. The bell-shaped calyx is 4-5-parted, and the 4-5 nearly equal petals have the claws united and crested at the apex. Stamens 7-10. Capsule 3-lobed, leathery.

Culture and Propagation.—This tree, although fairly hardy in the neighbourhood of London, is more suitable for the milder and warmer parts of the south and west. It will thrive in ordinary good garden soil like the Horse Chestnuts, and may be increased by layering the branches, or by sowing imported seeds in cold frames or greenhouses immediately upon arrival. It would also probably graft on stocks of the Common Horse Chestnut.

XANTHOCERAS.—A genus containing only one species described herewith and including the characters of the genus.

X. sorbifolia.—A beautiful Chinese tree 5-15 ft. high, with somewhat downy branches, and alternate, exstipulate, oddly pinnate leaves, having serrated leaflets, resembling the 'Mountain Ash' or 'Rowan tree' (*Pyrus Aucuparia*, p. 405). Flowers in June, white, over 1 in. across, with blood-red streaks at the base, regular, polygamous, produced in erect racemes 6-8 in. long. Sepals 5, equal, boat-shaped, imbricate. Petals 5, elongated, clawed, without scales. Disc cup-like, slender, with 5 horns alternate with the petals. Stamens 8. Fruit a 3-celled, oblong obtuse capsule, as large as a hen's egg.

Culture and Propagation.—This tree thrives in good light garden soil. It is hardy in the neighbourhood of London, but attains a greater size when grown on a south wall than if grown as a bush in the open. In the south of England and Ireland it flourishes and makes a charming flowering tree. In hot favourable seasons it ripens seeds freely, the large leathery

capsules opening when ripe much in the same way as those of the Horse Chestnut. It is usually increased by sowing seeds as soon as ripe in cold frames, but cuttings of the roots sometimes 'strike' if inserted in light sandy soil in gentle heat in autumn or early spring.

ACER (MAPLE).—A genus of about 50 species of beautiful trees and shrubs, containing a watery or sugary juice, many of them remarkable for the colours of the foliage. Leaves opposite, deciduous, palmately 3-7-lobed or parted, rarely entire. Flowers usually polygamous-dioecious, regular. Calyx 4-12-, often 5-parted. Petals equal in number to the sepals, or none. Disc ringed, fleshy, lobed. Stamens 4-12, often 8. Fruit of 2 spreading samaras with long wings or 'keys.'

The genus **NEGUNDO**, although retained as distinct by the authors of the 'Genera Plantarum,' is now usually merged with *Acer*, from which it would be scarcely possible to distinguish it except by means of its flowers. The following are the chief characteristics of the *Negundos*: flowers dioecious, calyx minute, 4-5-cleft or parted. Petals none. Disc obsolete. Stamens 4-6, hypogynous. Fruit like that of the Maples.

Culture and Propagation.—Most of the Maples thrive in deep, loamy, well-drained soil. The Japanese varieties have of late years become very popular, not only for the outdoor garden, but also as pot plants for the conservatory. They require a somewhat sheltered position outside, and are nearly all quite hardy.

Most Maples are easily raised from seeds sown in autumn or spring. Layering and grafting are employed for rare or choice varieties, and many are also budded during the summer. On the whole it is more satisfactory for the amateur to obtain established plants from a nurseryman.

A. argutum.—An elegant Japanese species having 5-lobed leaves, the lobes being rather sharply tapering to a point, and having more or less doubly serrate margins.

Culture &c. as above.

A. campestre (Common Maple).—A small British tree with rough bark full of fissures, having kidney-shaped, 5-lobed leaves. This species is chiefly met with in hedges in the southern counties. The variety *austriacum* has the lobes of the

leaves somewhat pointed; those of *collinum* (a French variety) being blunt; *hebecarpum* has downy fruits; *levigatum*, smooth and shining leaves; *nanum*, very dwarf; *tauricum* has larger and less lobed leaves than the type; and *variegatum* has leaves beautifully variegated with blotches and stripes of white and pale yellow. *Postelense* is a new form with yellowish leaves.

Culture &c. as above.

A. carpinifolium.—A very distinct and interesting Japanese species which attains a height of about 50 ft. in its native country. It is remarkable for having leaves quite unlike those of other *Acers* in shape. They are broadly oblong lance-shaped, 4-6 in. long, with coarsely toothed and serrated margins, and resemble those of the Hornbeam. The veins run obliquely from the midrib to the margin in parallel lines, and were it not for the fruits, this species might easily be mistaken as belonging to another genus.

Culture &c. as above.

A. caudatum (A. levigatum).—A distinct species from N. India, where it grows into a fairly large tree. The stems have dark brown bark, and the long slender purplish-red twigs are furnished with moderate-sized leaves, each of which is divided into 3 ovate and much-tapered lobes with coarsely toothed margins.

Culture &c. as above. Although a native of India it seems to be quite hardy in most parts of England and Ireland, though the young growths may be injured in the colder parts of Scotland in severe winters. It is readily increased by layers.

A. circinatum.—A beautiful shrub, 5-6 ft. high, native of N.W. America, having drooping branches and 7-9-lobed serrulated leaves which assume a bright scarlet colour in autumn. Flowers in April, deep red, umbellate.

Culture &c. as above.

A. cissifolium (Negundo cissifolium).—An elegant Japanese species 5-10 ft. high, with small, light green leaves divided into 3 leaflets.

Culture &c. as above.

A. creticum.—An almost evergreen species 4 ft. high, from the Levant. Leaves wedge-shaped at the base, sharply 3-lobed at the top.

Culture &c. as above.

A. dasycarpum (*A. eriocarpum*; *A. tomentosum*; *A. glaucum*; *A. virginianum*).—A N. American tree 40 ft. high. Leaves truncate at the base, 5-lobed, lobes unequally and deeply toothed, and of a beautiful silvery white beneath, and sometimes measuring 8 in. long without the stalk, by 10 in. broad.

Concerning this species Mr. Nicholson, of Kew, says, 'it is a fast-growing tree of the first rank for ornamental purposes, its graceful habit and handsome foliage causing it to be extensively planted as an avenue and general shade tree both in its native country and in Europe. The flowers which clothe the leafless branches in early spring somewhat resemble those of *A. rubrum*, but are not nearly so highly coloured as are those of that species; they expand too a fortnight or more earlier. In autumn the decaying foliage assumes a bright lemon-yellow tint, at any rate as far as I have observed in this country. Seeds are freely produced and ripened both in England and on the Continent, and a crowd of sports and seedling forms have received names in nurseries.'

Some of the most distinct forms are *aureo-variegatum*, the leaves of which are mottled with yellow; *laciniatum*, with the leaf-lobes more deeply cut and divided than in the type; *lutescens*, having yellowish tinted foliage; and *pulverulentum*, the leaves of which are spotted with white, and the tips of the young shoots are tinted with red.

Culture &c. as above, p. 313.

A. diabolicum (*A. pulchrum*).—An elegant Japanese Maple, remarkable for its large 5-lobed leaves, often measuring as much as 10 in. across. The lobes are more or less unequally toothed or shallowly lobed, while the whole margin is very distinctly defined. The large yellowish flowers in due course give place to clusters of beautiful winged fruits between the wings of which are 2 horn-like projections which probably suggested the specific name to the author of the species.

Culture &c. as above, p. 313.

A. distylum.—A distinct Japanese Maple with ovate un-lobed leaves 6-8 in. long, rounded at the base, tapering towards the tips, and having an irregularly toothed margin. The small yellowish flowers are replaced in autumn by clusters of pretty winged seed vessels.

Culture &c. as above, p. 313.

A. glabrum (*A. Douglasi*; *A. tripartitum*).—A North American tree 15-30 ft. high. Leaves roundish heart-shaped, deeply 3-5-lobed or parted, bi-serrate, light green.

Culture &c. as above, p. 313.

A. Heldreichi.—A distinct and handsome Maple, native of E. Europe, with rather leathery 3-5-lobed leaves, bright shining green above, and rather bluish-green beneath. The leaf-lobes are coarsely and bluntly toothed, and the general appearance reminds one of the foliage of the well-known Virginian Creeper (p. 309).

Culture &c. as above, p. 313.

A. heterophyllum (*A. sempervirens*). An evergreen species about 4 ft. high, native of the Levant, Asia Minor &c. Leaves small, ovate entire, 3-lobed, slightly serrate, smooth.

Culture &c. as above, p. 313.

A. ibericum.—A Caucasian species 20 ft. high, with bluntly 3-lobed leaves; lobes with 1 or 2 teeth, side ones distinctly nerved.

Culture &c. as above, p. 313.

A. insigne.—A pretty Caucasian species, very much resembling the Common Sycamore (*A. Pseudo-Platanus*) in the foliage. There is a form known as *velutinum*, which is distinguished chiefly by the slight velvety down on the under surface of the leaves.

Culture &c. as above. This is said to be one of the hardiest Maples in cultivation.

A. japonicum.—A beautiful species attaining a height of 20 ft. in its native country, Japan. Leaves many-lobed, light green in early spring. Flowers in April, large, deep purple-red. There are many varieties of this species, all worthy of cultivation. The best known are *aureum* with distinct golden foliage; *compactum* with a compact bushy habit; *laciniatum* with pale green deeply cut leaves; and *rufinerve albo-lineatum* with dark green leaves edged and marbled with creamy white.

Culture &c. as above, p. 313.

A. macrophyllum.—A tree 60 ft. high in its wild state in N. California. Leaves digitately 5-lobed, lobes again divided into three.

Culture &c. as above, p. 313.

A. monspessulanum.—A native of S. Europe 10–20 ft. high, with heart-shaped, 3-lobed leaves; lobes almost or quite equal, entire.

Culture &c. as above, p. 313.

A. montanum (*A. spicatum*).—A Canadian tree 18 ft. high, with 3–5-lobed leaves, unequally and coarsely serrated.

Culture &c. as above, p. 313.

A. Negundo (*N. fraxinifolium*; *Negundo aceroides*).—**Box Elder**; *Ash-leaved Maple*.—A very ornamental tree, native of N. America, where it grows 40 ft. high. Leaves pinnate, with 3–5 opposite coarsely and deeply toothed leaflets, the odd one at the apex usually 3-lobed.

There are several varieties, the best being *crispum*, with variously cut and curled leaves; *laciniatum*, with foliage still more deeply cut; and *variegatum*, a handsome variegated form better known than any of the others. It is usually budded on the green variety, and grown either as a bush or a standard. When not overplanted to the exclusion of other choice trees the Box Elder and its varieties make very beautiful groups in large gardens, parks &c.

Culture &c. as above, p. 313.

A. nikoëse (*Negundo nikoëse*).—A very distinct hairy Japanese shrub, with 3-foliolate leaves, and large fruits.

Culture &c. as above, p. 313.

A. oblongum (*A. laurifolium*).—A Himalayan tree 20 ft. high, with oblong lance-shaped, pointed, entire leaves.

Culture &c. as above, p. 313.

A. obtusifolium.—A native of Crete, 15 ft. high, with rounded bluntly 3-lobed crenate-serrate leaves.

Culture &c. as above, p. 313.

A. opulifolium (*A. Opalus*).—A native of France 8 ft. high, with heart-shaped, 5-lobed, coarsely toothed leaves, like those of the Guelder Rose (*Viburnum Opulus*). The variety *obtusatum* is larger and stronger, with dark green leaves covered with a white or rusty down beneath.

Culture &c. as above, p. 313.

A. palmatum (*A. polymorphum*; *A. dissectum*; *A. septemlobum*).—A handsome Japanese species about 20 ft. high in a wild state. Leaves palmately 5–7-lobed; lobes oblong, pointed, serrated.

This is the type of most of the

elegant beautifully coloured varieties in cultivation. Although no hard and fast line can be drawn between the various sections, it has however been found more or less convenient to arrange the various forms of *A. palmatum* under three heads as follows:

1. The **PALMATUM GROUP** proper.—The plants in this group are recognised by the leaves generally having 5 deeply cut lobes. There are many forms, but the following are among the most ornamental:—*aureum*, a strong-growing form with long-stalked rather large leaves, light green and yellowish when young, but assuming beautiful gold and orange-scarlet tints in autumn; *albo-marginatum*, the green leaves of which are edged with white; *crispum*, a very distinct form with green red-stalked leaves, rolled up at the edges. The habit is also quite distinct, somewhat resembling that of a miniature Lombardy Poplar; *linearilobum*, a form with narrow, slightly toothed or quite entire lobes, cut to very near the base of the leaves, which when young are red, as are also the shoots, but become green with age; there is a sub-form of *linearilobum* called *atropurpureum*, which differs in having deep bronzy purple leaves; *minor* has smaller leaves than the typical *palmatum*, they are at first green but assume a bronzy tint with age; *roseo-marginatum* has green leaves edged with rose; and *Shikara Jama* has finely serrated pale-green foliage suffused with red and blotched with dark olive-green.

2. The **SEPTEMLOBUM GROUP**.—The plants in this group are distinguished by the leaves being divided into 7–9 overlapping lobes, generally larger than those in the *palmatum* group. Among the many forms in this section may be mentioned:—*atropurpureum*, with bold dark purple foliage; *bicolor*, an attractive form rendered remarkable by the large carmine blotches on the leaf-lobes, one half of which is often of a very brilliant red; *elegans* has narrower and more deeply cut lobes than the typical *septemlobum*, which is a free-growing variety with pretty green leaves. They are of a delicate light green, flushed with red when young, but occasionally tinted with bronze; the sub-variety, *elegans purpureum*, is similar in form but of a much deeper bronzy-purple tint; *flavescens* has the young shoots and leaves more or less of a yellowish tint; *latifolium atropurpureum* has beautiful

bronzy-purple foliage; *lobatum* has broad overlapping irregularly cut lobes; *reticulatum* is recognised by the variegated network of yellow or white upon a light green ground; *sanguineum* (which is loosely known under many other names) has deep red leaves; *tricolor* has reddish leaves prettily streaked and blotched with creamy-white and rose; and *variegatum* comes very near, the young leaves and stalks being red, but streaked with white and rose when old. The green-leaved form of *A. septemlobum* is often used as a stock upon which the other varieties are budded or grafted.

3. The DISSECTUM GROUP.—This group is characterised by the leaves being cut into 7-9 overlapping lobes, each of which is again more or less deeply cut or incised from the margins to the midrib. The plants in this group are extremely graceful and feathery-like in foliage. The following are some of the best varieties:—The typical form has finely cut green leaves; *ornatum* is similar in appearance but the Fern-like leaves are of a beautiful deep red or bronzy-purple; *roseo-marginatum* has deep green leaves, bordered with rose and streaked with rose and white; *sessilifolium* is a very distinct form with deep green finely cut leaves and leaflets; and *vinctum* is almost similar to the typical green-leaved *dissectum*, from which, however, it may be distinguished by the reddish tinge of its beautifully cut foliage.

Culture and Propagation.—From an ornamental point of view, the many beautiful forms of *A. palmatum* quite eclipse all other Maples in cultivation, and of late years they have become immensely popular—so much so indeed that they are now very largely imported direct from Japan. As they do not as a rule grow very quickly and are rarely more than 3-6 ft. high, they are well adapted for growing in pots and in conservatories. Most of them are almost perfectly hardy, except perhaps in the coldest and bleakest parts of the kingdom. In such localities they must, however, be protected if necessary in severe winters by means of mats laced round a wicker work of sticks or canes. As for soil, they seem to flourish equally well in stiff heavy soil, in dryish sandy soil, and in peat. They are therefore suitable for planting in almost any garden the soil of which is in a fairly good and well-drained condition. They should not be mixed up with stronger and more coarse-growing

plants in the ordinary shrubbery, as they would thus stand a chance of being sooner or later smothered. To obtain the best effects they may be planted in groups by themselves in warm and sheltered spots, where, however, they will be fully exposed to the ripening influence of the sunshine, so that the brightest tints of the foliage may be highly developed. A mulching of well-rotted manure during the winter months will be of great value in supplying fresh food to the soil, and also for protecting the roots from severe frosts.

A. pectinatum.—A distinct species, native of Nepal and Sikkim, having leaves with 3-5 tapering lobes, the margins of which are remarkable for the fine bristly teeth or serratures. This character readily distinguishes it from *A. caudatum*, with which it has been confused, but the wings of the rose-tinted fruits are also spreading horizontally, instead of being more or less erect as in *A. caudatum*.

Culture &c. as above, and for *A. caudatum*.

A. pennsylvanicum (A. striatum).—A beautiful N. American tree 20 ft. high, with trunk striped with white lines. Leaves heart-shaped, 3-lobed, pointed, finely and sharply serrated.

Culture &c. as above, p. 313.

A. pictum.—A native of temperate Asia 15-20 ft. high, with 5-7-lobed, entire, pointed leaves.

The varieties *connivens*, *marmoratum*, *rubrum*, and *variegatum* differ chiefly in the colour tints of the foliage. A new variety named *tricolor* has the young leaves of a bright purple-red hue suffused with rosy-pink, and shading off into irregular masses of deep red or crimson and creamy-white.

Culture &c. as above, p. 313.

A. platanooides (Norway Maple).—An ornamental European tree 50 ft. high, with smooth, heart-shaped, 5-lobed leaves; lobes pointed with a few coarse sharp teeth. There are several varieties, such as *aureo-variegatum* with pale yellow, blotched leaves; *laciniatum*, leaves variously and deeply cut, green and yellow; *Schwedleri*, large deep bronzy-red leaves; *variegatum*, with white blotches, and many others such as the Eagle's or Kite's Claw, *cucullatum*, *Lobeli*, *purpureum*, *rubrum*, *columnare* &c.

Culture &c. as above, p. 313.

A. Pseudo-platanus (*Sycamore*; *Mock Plane Tree*).—An elegant tree 30-60 ft. high, with heart-shaped, 5-7-lobed, unequally toothed leaves. This has been so extensively planted all over the British Islands in all sorts of positions that it appears almost indigenous. It is really a native of Central Europe and W. Asia. Among the several varieties may be mentioned:—*albo-variegatum*, a beautiful form with white and green leaves; *flavo-marginatum*, green and yellow leaves; *longifolium*, leaves more deeply cut and longer stalked than the type; *purpureum*, leaves purple on the under surface. Other varieties worthy of note are *atropurpureum*, *aucubafolium*, *Leopoldi*, *Prinz Handjery*, *purpureo-variegatum*, and *webbianum*.

Culture &c. as above, p. 313.

A. rubrum (*Scarlet Maple*).—A beautiful Canadian species 20 ft. high. Leaves heart-shaped at the base, palmately 5-lobed, deeply and unequally toothed. Flowers scarlet, handsome, produced in great profusion in spring before the leaves. There are several varieties, one in which the leaves are variegated with white and yellow being very desirable but rather rare. Other forms are *Drummondii* and *sanguineum*, the latter being remarkable for the rich red colouring of the foliage.

Culture &c. as above, p. 313.

A. rufinerve.—A beautiful Japanese tree or shrub, the young branches of which are covered with a bluish-gray 'bloom.' Leaves 3-5-lobed, varying in size and shape, irregularly toothed, smooth above, with reddish hairs on the nerves beneath. The variety *albo-limbatum* is recognised by having as a rule leaves distinctly edged with white.

Culture &c. as above, p. 313.

A. saccharinum (*Bird's Eye* or *Sugar Maple*).—A North American tree 40 ft. high, with smooth, palmately 5-lobed leaves and yellow flowers. The variety *nigrum* has the lobes of the leaves closer together.

Culture &c. as above, p. 313.

A. sieboldianum.—A pretty Japanese Maple closely related to *A. japonicum*, from which it may be distinguished by its yellowish (not purple) flowers, and by its regularly 6-lobed leaves, the lobes of which are regularly serrated on the mar-

gins. The leaf stalks and flower stalks are also distinctly hairy.

Culture &c. as above, p. 313.

A. sikkimense.—A pretty Maple, native of the Sikkim Himalayas, where it grows naturally at an elevation of 7,000-9,000 ft. The ovate tapering leaves resemble those of *A. distylum*, but the serration on the edges is scarcely noticeable, and there are 5 main nerves instead of 3, as in *A. distylum*.

Culture &c. as above. This species is rather tender, but will survive ordinary winters in warm sheltered places in the neighbourhood of Kew. In Devonshire and Cornwall and the south of Ireland it would probably be almost perfectly hardy, except in very severe winters, when protection would be required.

A. tataricum (*A. cordifolium*).—A native of S.E. Europe about 20 ft. high, with oblong heart-shaped leaves irregularly toothed or rarely lobed. One of the first to leaf in spring. The form called *Ginnata*, from the banks of the Amur River, is a graceful variety with prettily cut and lobed leaves, having deeply coloured stalks and midribs.

Culture &c. as above, p. 313.

A. Volxemi (*A. Trautvetteri*).—A noble and distinct Caucasian Maple remarkable for its quick and vigorous growth and large 5-lobed leaves, the under surface of which is of a beautiful silvery white.

Culture &c. as above. An excellent tree for making avenues in parks and large gardens.

MELIANTHUS (HONEY FLOWER).

A genus consisting of only 4 species of very smooth, glaucous, or hoary shrubs, often strongly scented, with oddly pinnate alternate leaves. Flowers hermaphrodite, usually in terminal or axillary racemes. Calyx swollen at the base, 5-parted. Petals 5, eccentric, one minute or absent, bent down, long-clawed, hairy in the middle. Disc fleshy, one-sided. Stamens 4, hypogynous, inserted in the disc, two long, two short, and bent down somewhat. Style incurved, thread-like, 4-toothed at apex. Capsule papery, 4-lobed, 4-celled.

M. major.—A native of S. Africa 4-6 ft. high, with hollow stems woody at the base. Leaves stem-clasping, smooth, glaucous, with 4-6 pairs of deeply cut leaflets and an odd one at the apex. Flowers in summer, brownish, in long axillary spikes among the upper leaves.

This is the species usually grown, but *comosus*, *minor*, and *pectinatus* are also worth growing outside in summer for subtropical groups on the lawn.

Culture and Propagation.—The Honey Flowers are not, strictly speaking, hardy plants, but they are grown so easily from seeds and look so effective in the garden from early summer to the end of autumn that they are well worth growing. Seeds may be sown in February or March in a little heat. The seedlings may be pricked off separately into small pots when large enough, and will be ready for planting out by June. Larger plants may be obtained by sowing in the autumn and keeping the plants in a greenhouse during the winter. They may also be increased for indoor work by cuttings, which strike freely under a bell-glass. On a well-drained, loamy soil and in sheltered positions the *Melianthus* may be wintered outside with a slight protection of litter or leaves in the mildest parts of the kingdom.

STAPHYLEA (BLADDER NUT).—A genus of 5 species of deciduous branched shrubs, with opposite 3-5-foliolate or pinnate leaves, and white regular hermaphrodite flowers in drooping axillary racemes or panicles. Sepals 5, equal. Petals 5, erect. Stamens 5, equal, inserted at the base of the outside of the rather flat disc. Fruit a bladder-like capsule.

Culture and Propagation.—The Staphyleas thrive in good well-drained ordinary soil, the most popular being *S. colchica*, which is much used in early spring for forcing in greenhouses, when specially treated. For outdoor cultivation the plants may be placed in groups by themselves in warm and sheltered places enjoying a slight shade, and for massing on grass they are very effective. They are increased by suckers and layers, or cuttings of the ripened shoots taken in the autumn and inserted in sandy soil under a bell-glass. Seeds are also freely produced by some of the species such as *colchica*, *pinnata*, and *trifolia*, and from these fresh plants may be obtained. The seeds may be sown in cold frames as soon as ripe, afterwards pricking the seedlings out when large enough. *S. colchica* and *S. pinnata* have been crossed with each other and have produced a hybrid called *S. Coulombieri*.

S. Bolanderi.—A Californian shrub

with leaves divided into 3 smooth broadly oval or round leaflets, abruptly acute and serrulate. Sepals and petals about $\frac{1}{4}$ in. long; style and stamens protruding.

Culture &c. as above.

S. Bumalda.—A Japanese species 6 ft. high. Leaves 3-foliolate, with oblong pointed, roughish leaflets having bristly serratures on the margin. Flowers from June to August; styles hairy, capsule 2-beaked.

Culture &c. as above.

S. colchica.—A distinct Caucasian species 3-5 ft. high, with ternate and pinnately 5-foliolate leaves 4-5 in. long, composed of ovate-oblong pointed serrulate leaflets. Flowers in summer, $\frac{3}{4}$ in. long, in terminal, erect or slightly nodding racemes.

Culture &c. as above.

S. pinnata (Job's Tears; St. Anthony's Nuts).—A native of S. Europe 6-12 ft. high, with leaves composed of 5-7 pairs of oblong smooth, serrated leaflets. Flowers in racemes, succeeded by globose white nuts in a bladder capsule.

Culture &c. as above.

S. trifolia.—A pretty North American species 6-12 ft. high, with 3-foliolate leaves divided into ovate pointed regularly serrated leaflets, downy when young. Flowers in early summer, with obovate spoon-shaped petals fringed at the base.

Culture &c. as above.

EUSCAPHIS.—A genus containing only 2 species of very smooth shrubs with round branches and opposite, stipulate, oddly pinnate leaves composed of serrate leaflets. The small hermaphrodite flowers are borne in panicles at the ends of the branches. Calyx persistent, 5-cleft. Petals 5, roundish, imbricate. Disc annular, crenate. Stamens 5, with filaments dilated at the base. Fruit consisting of 1-3 follicles.

E. staphyleoides (E. japonica).—A rather ornamental shrub 10-12 ft. high, native of China and Japan. It has smooth pinnate leaves, and clusters of small white or yellowish flowers produced at the ends of the branches in early summer. In the autumn the plant is rendered attractive by the red bladderly fruits or follicles.

Culture and Propagation.—This species will flourish in ordinary good garden soil, especially if it consist chiefly of rich loam. A warm sheltered situation

suits it best. It may be increased by cuttings of the ripened shoots placed in light soil under a handlight, and also by

seeds sown in cold frames as soon as ripe. In Japan it is said this plant is highly valued for its medicinal virtues.

XXXVI. ANACARDIACEÆ—Sumach Order

An order containing 450 species of trees or shrubs with a resinous milky juice. Leaves usually alternate, pinnate, trifoliolate or simple. Flowers hermaphrodite, or polygamous, dioecious, or unisexual, usually regular. Calyx 3-7-cleft or parted. Petals 3-7, rarely absent, usually free, stamens often twice as many as petals, rarely equal in number, or very numerous.

RHUS (SUMACH).—A genus containing 120 species of trees or shrubs abounding in resinous or caustic juice. Leaves alternate, simple, 1-3-foliolate or oddly pinnate. Flowers very small, polygamous, in axillary and terminal panicles. Calyx 4-6-parted; lobes equal imbricate. Petals 4-6, equal spreading. Stamens 4, 5, 6, or 10, free, inserted at the base of the ringed disc. Fruit a small dry compressed drupe.

Culture and Propagation.—The Sumachs are mostly useful for shrubberies, some of them like *Rhus Cotinus* being useful for rough places or under trees. They are excellent for planting in rather dry spots, as they are not so much affected by the absence of moisture as are many other shrubs. They thrive in ordinary garden soil, and are increased chiefly by cuttings of the roots or ripened portions of the stems, or by layers.

R. aromatica (*R. suaveolens*).—A N. American shrub 8 ft. high, with downy leaves when young, thickish when old, and sweet-scented when crushed; leaflets 3, rhomboid-ovate, unequally cut and toothed. Flowers about April and May, pale yellow, in catkin-like spikes before the leaves appear, afterwards followed by red roundish fruits about the size of Currants. The variety *trilobata* is distinguished by its smaller leaves, the leaflets of which are distinctly lobed near the apex, and the odour is not so pleasant as in the type.

Culture &c. as above.

R. copallina.—A somewhat downy N. American shrub 1-7 ft. high. Leaves with winged stalks, and 9-21 oblong or ovate lance-shaped often entire leaflets, smooth and shining dark green above, downy beneath. Flowers in summer, greenish-yellow, in dense clusters at the ends of the shoots. The female flowers are borne on one plant, the male ones on another.

Culture &c. as above. In its native

country this species grows 25-40 ft. high, and its foliage assumes beautiful tints.

R. Coriaria.—A native of S. Europe, 15-20 ft. high, with hairy leaves, composed of 11-15 elliptic, large, bluntly toothed leaflets becoming purple-red in autumn. Flowers in summer, whitish-green. This species furnishes the Sumach of commerce, but is very rarely met with in cultivation.

Culture &c. as above. It is hardy perhaps only in the mildest parts of the kingdom.

R. cotinoides (*Cotinus americanus*). This is the 'Chittam Wood' of the South United States, where it assumes the proportions of a small tree 25-35 ft. high, with a trunk over 1 ft. in diameter. It is only a small shrub in cultivation, and very much resembles the European *R. Cotinus* in appearance, but is not so bushy in habit. The large roundish and undivided leaves form the chief beauty of the plant, especially in the autumn when they assume beautiful shades of scarlet and crimson suffused with tints of yellow and orange.

Culture &c. as above. As this species is very scarce even in its native country, care should be taken to see that the following species is not supplied in its place.

R. Cotinus (*Smoke Plant; Wig Tree; Venetian Sumach*).—A graceful slender-stemmed shrub 6-8 ft. high, native of S. Europe, with obovate or circular, shortly stalked leaves about 1-3 in. long. Flowers in June and July, pale purple or flesh-coloured outside, in loose panicles, the pedicels becoming hairy and lengthened after flowering. The variety *pendula* has drooping instead of erect branches, and *atropurpurea* is remarkable for the purple hues of the leaves, young shoots, and flower clusters.

Culture &c. as above. This species

will flourish in almost any soil. The leaves look very ornamental in autumn when they assume a rich yellow colour, often turning to bronzy-purple. Seeds are freely produced.

R. glabra (*R. caroliniana*; *R. cocinea*; *R. elegans*; *R. sanguinea*).—A beautiful N. American shrub 5-8 ft. high, with smooth leaves divided into 17-21 lance-shaped oblong serrate leaflets, whitish beneath. They assume rich red tints in autumn. Flowers in June, males greenish-yellow, females greenish-red. Seeds are freely produced, and the clusters of fruits look very handsome during the autumn and winter months. The variety *laciniata* (known as the 'Fern-leaved Sumach') is very elegant, with beautifully cut and divided leaflets longer and broader than in the type.

Culture &c. as above, p. 319.

R. Michauxi.—A native of the South United States having erect stems 2-3 ft. high, and spreading extensively by means of underground creeping rootstocks. The leaves are pinnately divided, but the beauty of the plant consists largely in the bright scarlet pyramidal fruit clusters, which are clothed with a silky down.

Culture &c. as above. This species is not yet well known, but it may become a very popular plant, should it prove quite hardy in this country.

R. Osbecki.—A very distinct and handsome shrub, native of China and Japan, where it attains a height of about 20 ft. The large pinnate leaves are composed of 5 or more pairs of leaflets, some of which are about 6 in. long and 4-5 in. broad, with large blunt teeth on the margins, and a short down beneath. The leaf stalk in between the leaflets is winged as in *R. copallina*, and in autumn the foliage assumes beautiful tints of red and orange, which are more vivid in favourable seasons. The unattractive flowers are produced in July and August in large clusters at the ends of the branches, and seeds are freely produced.

Culture &c. as above.

R. succedanea (*Red Lac Sumach*).—A beautiful Japanese shrub 10-15 ft. high, with smooth leaves over 1 ft. long and divided into several pairs of ovate lance-shaped tapering leaflets, netted with veins, glaucous beneath. Flowers in sum-

mer, greenish-yellow, succeeded by white Cherry-like fruits.

Culture &c. as above. This species is usually grown in a cool greenhouse, but will grow well out of doors in the milder parts of the country. It is remarkable for the beautiful reddish and crimson tints of the young leaves, which turn green as they develop, but again assume coloured hues in autumn before they fall.

R. Toxicodendron (*Poison Ivy*; *Poison Oak*).—A somewhat climbing N. American and Japanese species with leaves divided into 3 leaflets, 1½-6 in. long, rhomboid-ovate, pointed, rather downy beneath, variously notched and lobed. Flowers in June, greenish-yellow.

Culture &c. as above. This remarkable plant should be carefully handled, as it has poisonous effects on some people. The variety *radicans* has leaves almost or quite entire. In shady places both species and variety may be allowed to ramble over rocks or boulders, tree stumps &c., looking very pretty in autumn with the purple-red coloured foliage. Seeds are freely produced.

R. trichocarpa.—A beautiful shrub or small tree recently introduced from Japan, where it grows 20-25 ft. high. The leaves are about 20 in. long with deep red midribs, and broadly ovate, tapering leaflets, which assume bright scarlet and orange tints in autumn in a wild state. The unattractive flowers are produced in July, and give place later on to drooping clusters of large prickly drupes.

Culture &c. as above. Only small plants are at present in cultivation, and, according to Mr. Bean, they have coloured well at Kew. Should this species prove hardy in our climate, and colour well, it will be a great acquisition for producing fine effects in autumn.

R. typhina (*Stag's Horn Sumach*; *Vinegar Tree*).—A well-known N. American tree 10-30 ft. high, with large hairy pinnate leaves and densely hairy thick shoots. Leaflets 11-31, glaucous beneath, oblong lance-shaped, pointed, deeply serrate, the veins and main rachis clothed with velvety rusty hairs. Flowers in June and July, greenish-yellow, in erect cone-like clusters, the male and female flowers being borne on separate plants. Seeds are freely produced, and the fruit clusters being clothed with deep crimson or dull reddish hairs look very attractive

in autumn and winter. The variety *arborescens* has leaves slightly downy beneath; and *frutescens* downy and whitish beneath.

Culture &c. as above.

R. venenata (*R. vernix*).—*Poison Elder*, *Sumach*, or *Dogwood*.—A very poisonous but handsome N. American tree 6–18 ft. high, with rather smooth leaves composed of 7–13 obovate-oblong entire leaflets. Flowers in July, green, in loose slender axillary panicles. The female plants occasionally produce ripe seeds contained in small Pea-like berries which hang down in graceful clusters in autumn.

Culture &c. as above. Great care should be taken not to let the juice of this plant touch the hands or any part of the body, as it is quite as poisonous as *R. Toxicodendron*.

R. vernicifera (*Japan Lacquer* or *Varnish Tree*).—A Japanese tree 30 ft. high with Walnut-like leaves, having 11–13 elliptic acute entire leaflets, smooth above, with a velvety down beneath. Flowers in June, greenish-yellow.

Culture &c. as above. This is a very graceful shrub, and will survive an ordinary winter out of doors, except, perhaps, in the bleakest and coldest parts of the British Islands. It likes a warm sheltered situation and plenty of sunshine.

PISTACIA.—A genus of half a dozen evergreen or deciduous trees or shrubs abounding in resinous juice, with alternate leaves, with or without an odd leaflet at the apex, sometimes 3-foliolate. Flowers small without petals, diœcious, in axillary clusters. Calyx 5-cleft or parted in the male flowers; 3–4 in the female ones. Stamens 5, very short; absent in

the female flowers. Fruit a dry one-seeded drupe.

Culture and Propagation.—The Pistacias thrive in a rich, deep, sandy loam in sheltered situations against a wall. They may be increased by layers or cuttings of the ripened shoots inserted in autumn under a handlight or in gentle heat. As garden plants the Pistacias are not of great value, although they are important from an economical point of view.

P. atlantica.—An evergreen tree, 40 ft. high, native of the Canary Islands, with oddly pinnate leaves, leaflets tapering to the base.

Culture &c. as above.

P. Lentiscus (*Mastich Tree*).—Native of S. Europe 20 ft. high, with abruptly pinnate leaves, having winged stalks and lance-shaped leaflets. Flowers in spring, green. This plant yields the drug Mastich. The variety *angustifolia* has almost linear leaflets; in *chia* they are ovate.

Culture &c. as above.

P. Terebinthus (*Turpentine Tree*).—A deciduous tree 30 ft. high, native of S. Europe, with numerous ovate lance-shaped leaflets, of a beautiful reddish hue when young. Flowers in June, greenish, with dull yellow anthers and crimson stigmas.

The Chian or Cyprr Turpentine is obtained from this tree by making incisions in the trunk.

Culture &c. as above.

P. vera (*Pistachio Nut Tree*).—A deciduous Syrian tree, 20 ft. high, with pinnate leaves, and ovate leaflets tapering at the base. Flowers in April, brownish-green. Fruits about 1 in. long, ovate, reddish, with an oblique point.

Culture &c. as above.

XXXVII. CORIARIEÆ

An order of unarmed shrubs with angled branches and usually opposite ovate heart-shaped or lance-shaped leaves, 1–5-nerved, entire, smooth, without stipules. Pedicels axillary or racemose, with small greenish hermaphrodite or almost polygamous flowers. Sepals 5. Petals 5, shorter than the sepals, hypogynous, fleshy, keeled outside. Stamens 10, hypogynous, free, or adnate to the keel of the petals. Carpels 5–10, distinct, more or less fleshy.

CORIARIA.—This is the only genus of the order, and its botanical characters are as described above. It contains five or six species, but the one described below is the only hardy one at present much

known. There are, however, a few other species in cultivation, viz. *C. nepalensis* from the Himalayas, and *C. thymifolia* from Peru; *C. japonica* and *C. terminalis* from Japan.

C. myrtifolia.—A handsome shrub 3-6 ft. high, native of S. Europe. Leaves ovate lance-shaped, simple, 3-nerved, smooth and glaucous, on very short stalks. Flowers from May to August, greenish.

Culture and Propagation.—It will grow in ordinary garden soil, and may be increased by suckers or layers in the autumn. Seeds may also be sown as soon as ripe, or in spring in cold frames.

Series III. CALYCIFLORÆ (see p. 124)

XXXVIII. LEGUMINOSÆ—Laburnum and Broom Order

A very extensive order with 6,500 species growing in all parts of the world. It is divided into three large suborders, Papilionaceæ, Cæsalpineæ, and Mimosæ. The two first named are the only ones represented out of doors in the British Islands, and their characters are described in proper sequence, with the genera and species belonging to each.

SUB-ORDER I. PAPILIONACEÆ.

The plants in this group consist of trees shrubs or herbs of very varied character. Leaves with 2 stipules, alternate, simple or often digitately or pinnately compound. Flowers irregular, usually hermaphrodite. Sepals usually 5 more or less united. Petals 5, unequal; the upper one (known as the 'standard') free, larger than the 2 side ones (known as the 'wings'), which latter enclose and sometimes adhere to the 2 more or less united and upward curved lower ones (known as the 'keel'). The keel usually encloses the 10 perigynous stamens, united in a sheath, or the upper one only free; rarely all free. Fruit a 1-celled, usually dehiscent pod, with one or more seeds.

ANAGYRIS.—A small genus of shrubs with alternate stalked digitately 3-foliolate leaves, opposite which are placed two united stipules. Flowers rather large, yellow, borne in short racemes at the tips of the branches. Calyx teeth or lobes nearly equal. Standard shorter than the oblong wings, roundish, not reflexed at the sides. Stamens free.

A. foetida.—A rather ornamental shrub 6-8 ft. high, native of S. Europe, and remarkable for the disagreeable odour it emits when bruised. The leaves are composed of three spreading lance-shaped acute leaflets, and the yellow hairy Laburnum-like flowers are produced in May and June in short racemes at the tips of the branches.

Culture and Propagation.—This species is hardy as far north as the Thames Valley in ordinary winters, but would probably require protection in the event of severe weather. It may be grown in well-drained sandy loam and

peat or leaf-soil in warm and sheltered spots with plenty of air. It may be increased during the summer months by inserting cuttings of the half-ripened shoots in sandy soil under a handlight and protecting them under glass until the following spring.

PIPTANTHUS (*Nepalense Laburnum*).—A genus, the characters of which are described in the only species it contains, viz. :—

P. nepalensis (*Thermopsis nepalensis*). A handsome evergreen shrub, about 10 ft. high, native of Nepal, with alternate, stalked, digitately 3-foliolate leaves, and lance-shaped-acute, slightly hairy leaflets. Flowers in spring, large, yellow, in short racemes at the ends of the branches. Calyx-lobes almost equal; standard reflexed at the sides; wings obovate oblong; keel scarcely incurved. Stamens 10, free.

The variety *aurea* may be recognised

by means of the yellow and green stripes on the bark. Closely related is *P. tomentosus* from China, which, however, may be distinguished by the silky down which covers the leaves and branches.

Culture and Propagation.—This plant is best on sheltered walls in the milder parts of the country, in rich sandy loam, although in favourable places it may also be grown as a bush like the Laburnum. It is only in severe winters that the tips of the shoots are likely to be injured. It is easily increased by seeds which ripen in this country. They may be sown under glass as soon as ripe, or in spring, afterwards pricking the seedlings out and growing on for a season or two in pots until the plants are large and strong enough to be placed out of doors. Cuttings of the ripened shoots will also root, and layers may be made in autumn.

THERMOPSIS.—A genus containing about 12 species of perennial herbs, with alternate digitately 3-foliolate leaves, and free leafy stipules. Flowers in terminal racemes, or opposite the leaves. Calyx more or less bell-shaped with nearly equal lobes or teeth. Standard almost equal to the oblong wings, reflexed at the sides; keel almost equal to or longer than the wings. Stamens 10, free. Pods almost sessile or slightly stalked.

Culture and Propagation.—These plants succeed best in light rich well-drained soil, and are most surely increased from seeds, sown either as soon as ripe, or in spring, in cold frames or in gentle bottom heat. When the roots are divided the plants not unfrequently die.

T. barbata.—A Himalayan perennial 1 ft. or more high, with sessile smoothish often opposite leaves, and oblanceolate leaflets, and similar stipules. Flowers in June, deep purple, 1 in. long.

Culture &c. as above.

T. corgonensis.—A plant 1-2 ft. high native of the Corgan Alps. Leaves sessile or very shortly stalked, with ovate acute leaflets, which with the leafy stipules make a half-whorl. Flowers in summer, twin, yellow, almost stalkless.

Culture &c. as above.

T. lanceolata (*Podalyria lupinoides*). A native of Kamtschatka about 1 ft. high. Leaves almost stalkless with

oblong lance-shaped leaflets having silky down on both surfaces; stipules half as long as the leaflets. Flowers in summer, twin, yellow, with large bracts.

Culture &c. as above.

T. montana (*T. fabacea*).—A beautiful silky-haired N. American perennial 1-2 ft. high. Leaves stalked with broadly ovate leaflets, and broadly ovate blunt stipules. Flowers in summer, yellow, alternate.

Culture &c. as above.

BAPTISIA (*False Indigo*).—A genus with about 14 species of herbaceous perennials, all natives of N. America. Leaves alternate digitately 3-foliolate, or simple and sessile, or perfoliate. Stipules usually small, or rarely large and leafy. Flowers white, yellow or blue in terminal racemes, or opposite the leaves on a stalk. Calyx obtuse or somewhat bell-shaped. Petals almost equal, the standard being roundish, reflexed at the sides; the wings oblong, and the keel slightly curved upwards. Stamens 10, free. Pod stalked, ovoid or nearly globose, swollen, often leathery.

Culture and Propagation.—The Baptisias grow freely in rich loamy soil, and may be easily increased from seeds sown in cold frames as soon as ripe, or out of doors in mild weather in spring; or by dividing the rootstock very carefully in early autumn, or in spring as growth is commencing.

B. alba.—A pretty perennial about 2 ft. high. Leaves stalked, smooth, with elliptic oblong blunt leaflets. Flowers in June, white.

Culture &c. as above.

B. australis.—A fine species 4-5 ft. high, with spreading branched smooth stems. Leaves glaucous, stalked, smooth, with blunt oblong wedge-shaped leaflets and lance-shaped acute stipules twice the length of the leaf stalk. Flowers in June, purple or blue, with white keels.

Culture &c. as above. This is the best and most generally grown species, and when grown in large masses produces a fine effect. There is a variety called *versicolor*.

B. confusa.—A plant 1-2 ft. high, with smooth-stalked leaves, oblong wedge-shaped leaflets, and linear lance-shaped stipules twice the length of the leaf stalk. Flowers in June, dark blue.

Culture &c. as above.

B. exaltata.—A pretty perennial 3-4 ft. high. Leaves ternate, stalked; leaflets lance-shaped obovate; stipules 3 times longer than the leaf stalk. Flowers in June, deep blue.

Culture &c. as above.

B. leucophaea.—A perennial about 1 ft. high. Leaves unstalked, rather hairy; leaflets rhomboid-obovate; stipules and bracts ovate acute, broad, leafy. Flowers in July, creamy-white, all leaning to one side.

Culture &c. as above.

B. minor.—A plant 1-2 ft. high. Leaflets rhomboid lance-shaped; stipules lance-shaped, longer than the leaf stalks. Flowers in June, blue.

Culture &c. as above.

B. perfoliata.—A pretty perennial about 3 ft. high. Leaves perfoliate, roundish, entire, glaucous. Flowers in August, yellow, small.

Culture &c. as above.

B. tinctoria.—A handsome species 2-3 ft. high. Leaves stalked; leaflets roundish obovate; stipules bristly, almost obsolete. Flowers in summer, yellow.

Culture &c. as above. Unless this species finds itself in a really favourable situation one is apt to regard it as an inferior plant.

LUPINUS (LUPINE).—A genus consisting of 80 species of herbaceous annuals and perennials, rarely undershrubs. Leaves simple, or digitately 5-15- or many-foliolate, rarely 3-foliolate; stipules adnate to the base of the leaf stalk. Flowers in erect terminal racemes. Calyx deeply 2-lobed. Standard petal roundish or broadly ovate; wings sickle-shaped-oblong or obovate, united at the tips; keel ending in a curved beak. Stamens 10, united in one bundle. Pod more or less compressed, silky-haired, leathery or fleshy.

Culture and Propagation.—The Lupines nearly all thrive in ordinary good garden soil. They will not, however, flourish in soils heavily charged with chalk or lime. The presence of either of these ingredients may be readily detected by beating up a little of the soil in a tumbler of clean, and if possible distilled, water. After allowing the soil to settle at the bottom, the water may be breathed into strongly. If it assumes a milky colour, then lime is present.

The annual and perennial kinds may both be easily raised from seeds sown in early spring out of doors in the places where the plants are to flower. As the annual kinds do not bear transplanting very well, the seeds should be sown very thinly, and afterwards if the plants are too close together they must be thinned out. The perennials may be further multiplied by dividing the rootstocks at the same period.

Lupines are easily recognised by their radiating leaflets as well as their tall spikes of blossom. They are very valuable for the decoration of the herbaceous border when grown in bold masses, and some of the finest may be grouped in large beds on the grass.

L. affinis.—A Californian perennial about 9 in. high, with deep blue flowers.

Culture &c. as above.

L. arboreus (*Tree Lupine*).—A roundish bush 2-4 ft. high, with lanceolate-linear leaflets clothed with a soft silvery down. The beautiful fragrant yellow flowers appear in great profusion in summer. There is a purple-flowered variety and some inferior yellow ones.

Culture and Propagation.—This fine species differs from the annual and herbaceous perennial kinds in being of a more or less woody character. In favourable situations it attains a very great size and diameter, and when covered with its fragrant blossoms is very attractive. Being a native of California it likes warm, sunny and sheltered situations, and in unfavoured parts of the kingdom may be grown against a south wall. It may be increased by seeds sown in a cold frame or pots when ripe, and also by cuttings of the plump and fairly well-ripened shoots in summer, inserted in sandy soil in a cold frame or in gentle bottom heat.

L. aridus.—A N. American perennial 1 foot high, with linear lance-shaped leaflets. Flowers in late summer, purple-blue.

Culture &c. as above.

L. Chamissonis (*L. albifrons*).—A Californian perennial 3 ft. high, covered with a silvery silky down. Leaflets obovate-oblong, narrowed at the base. Flowers in September, blue.

Culture &c. as above. Increased by seeds and division.

L. fallax.—An ornamental bush 3-5 ft. high, native of Mount Tamalpais, to the west of San Francisco Bay. It has a neat symmetrical habit, and silvery leaves divided into 7-9 linear lance-shaped acute leaflets $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long. The beautiful violet-coloured flowers are borne in summer on long spikes in great profusion.

Culture &c. as above for *L. arboreus*. This plant requires to be grown in a warm sheltered position.

L. Hartwegi.—A beautiful Mexican species $1\frac{1}{2}$ -2 ft. high. Leaflets 7-9, oblong lance-shaped; stipules linear, very long. Flowers late in summer, varying from pale to dark blue, the standard petal shaded with white or rose. There are white and rose-coloured forms.

Culture and Propagation.—This ornamental species is in reality a perennial in warm dry localities, but in unfavourable parts it is likely to perish in winter; it is therefore best treated as an annual, and raised from seeds every year as recommended above for *L. luteus*.

L. laxiflorus (*L. arbustus*).—A North American perennial 12-18 in. high, with linear lance-shaped leaflets. Flowers late in summer, blue, the keel and base of the wings being reddish.

Culture &c. as above. Increased by seeds or division.

L. lepidus.—A perennial about 6 in. high, native of N. America, with lance-shaped leaflets silky on both sides. Flowers in late summer, purple-blue, the standard petal having a white spot at the base.

Culture &c. as above. Increased by seeds or division.

L. leptophyllus.—A Mexican perennial 1-3 ft. high. Leaflets linear acute, with a few silky hairs on each surface. Flowers in summer, violet.

Culture &c. as above. Increased by seeds or division.

L. leucophyllus (*L. plumosus*).—A very hairy N. American perennial 2-3 ft. high, with 7-9 oblong-lance-shaped leaflets and awl-shaped woolly stipules. Flowers from June to November, pink.

Culture &c. as above. Increased by seeds or division.

L. littoralis (*L. nootkatensis fruticosus*; *L. versicolor*).—A N. American perennial 1 ft. high. Leaflets 5-7, linear spoon-shaped, silky on both surfaces.

Flowers from June to October, purplish-blue.

Culture &c. as above. Increased by seeds or division.

L. luteus (*L. odoratus*).—A S. European annual 1- $1\frac{1}{2}$ ft. high. Leaflets 7-9, oblong, lower ones obovate. Flowers from June to August, yellow, fragrant. The variety *leucospermus* has entirely white seeds.

Culture &c. as above. Seeds may be sown out of doors in April and May, and in the milder parts of the country in early autumn as soon as ripe.

L. Menziesi (*L. sulphureus*).—A remarkable silky-haired Californian annual, about 2 ft. high. Leaflets 9-11, oblong lance-shaped. Flowers in July and August, slightly fragrant, sulphur-yellow to orange. The variety *superbus* is a finer flowering form.

Culture &c. as above for *L. luteus*. Seeds to be sown annually.

L. Micheneri.—An herbaceous perennial, native of N. California. It has a somewhat trailing habit, and looks pretty in spring and summer, although the dull purple or brownish-green flowers are not particularly attractive.

Culture &c. as above. Increased by seeds and division.

L. microcarpus.—A N. American annual $1\frac{1}{2}$ ft. high. Leaflets 9-10, lance-shaped, smooth above, hairy beneath. Flowers in April, blue, about 6 in a whorl.

Culture &c. as above for *L. luteus*. Seeds to be sown annually.

L. mutabilis.—A beautiful Colombian annual 3-4 ft. high; leaflets 7-9, bluntly lance-shaped, rather glaucous and downy beneath. Flowers from June to August, fragrant, large, the standard petal white changing to blue, with a large yellow mark in the centre; wings white faintly striped; keel white. *Cruikshanki* and *varicolor* are desirable varieties. The plant known as *hybridus atrococcineus* is a beautiful free-flowering variety with deep scarlet blossoms, and has probably originated from forms of *L. mutabilis*.

Culture &c. as above, and as for *L. luteus*. Seeds to be sown annually.

L. nanus (*Common Dwarf Lupine*). A pretty Californian annual 1 ft. or more high. Leaflets 5-7, narrow lance-shaped acute, hairy. Flowers in early

summer, lilac and blue. The variety *albus* has white flowers; *albo-coccineus* is very compact in habit, with flowers white and rosy-carmine.

Culture &c. as above for *L. luteus*. Seeds to be sown annually. This species and its varieties are very free-flowering and are effective in beds or masses.

L. nootkatensis.—A perennial 1-1½ ft. high, native of Nootka Sound. Leaflets 7-8, obovate lance-shaped, hairy. Flowers from May to July, blue, mixed with purple, white or yellow, and streaked with deeper veins.

Culture &c. as above. Increased by seeds or division.

L. ornatus.—A N. American perennial 1-2 ft. high. Leaflets linear lance-shaped, covered with silvery silky down on both sides. Flowers from May to November, pale blue, with deeper coloured wings, and a ciliated keel.

Culture &c. as above. Increased by seeds or division.

L. perennis.—A pretty perennial about 2 ft. high, native of N. America. Flowers from May to July, blue.

Culture &c. as above. Increased by seeds or division.

L. pilosus (*L. hirsutus*).—A hairy S. European annual 2-4 ft. high. Leaflets 9-11, oblong lance-shaped. Flowers in summer, blue, the centre of the standard petal deeper in colour. The variety *alba* has white flowers, and *roscus* pale rose ones.

Culture &c. as above for *L. luteus*. Seeds to be sown annually.

L. polyphyllus (*L. grandifolius*; *L. macrophyllus*).—A strikingly beautiful and well-known vigorous perennial 3-6 ft. high, native of California. Leaflets 11-15, lance-shaped, hairy beneath. Flowers in summer, in great profusion, varying from blue to purple and reddish-purple and white. There are several variations known as *albiflorus*, *argentus*, *fervosus*, *laxiflorus*, *Lachmanni*, *rivularis* &c. *Variiegatus* has violet-blue flowers streaked with white. The white-flowered variety (*albiflorus*) is very charming, and the only way to increase a really good form of it is by dividing the root clumps.

Culture &c. as above recommended for the perennial species. Seeds may be also sown in cold frames as soon as ripe, or a few in small pots, from which latter

the seedlings may be transferred in spring without breaking the ball of soil.

L. pubescens.—A branching downy annual 2-3 ft. high, native of Mexico and Guatemala. Leaflets 7-9, lance-shaped; stipules awl-shaped. Flowers from July to September, violet-blue, with a white centre, becoming deep purple. *Ehrenbergi* is a variety of this species.

Culture &c. as above for *L. luteus*. Seeds to be sown annually.

L. Sabini.—A N. American perennial 2-3 ft. high. Leaflets 7-12, lance-shaped, pointed, silky. Flowers in early summer, yellow.

Culture &c. as above. Increased by seeds and division.

L. subcarnosus (*L. bimaculatus*; *L. subramosus*; *L. texensis*).—An elegant downy-stemmed annual about 1 ft. high, native of Texas. Leaflets 5, obovate lance-shaped, thick or fleshy. Flowers from July to September, deep rich blue, with a yellow blotch at the base of the standard petal; keel white, tipped with blue.

Culture &c. as above for *L. luteus*. Seeds to be sown annually.

L. tomentosus.—A beautiful Peruvian perennial 4-5 ft. high, covered with short silky hairs. Leaflets 8-10, oblong, bluntish, mucronulate, tapering to the base. Flowers in summer, large, variously coloured blue, purple, rose &c.

Culture &c. as above. Increased by seeds or division. This species may not be quite hardy in the coldest parts of the country.

L. tricolor elegans (*L. Dunnetti*).—A very pretty slightly downy annual of uncertain origin. Leaflets 7-9. Flowers in summer, standard petal deep violet or purple becoming deeper in colour with age; wings and keel white.

Culture &c. as above for *L. luteus*. Seeds to be sown annually.

L. varius (*L. semiverticillatus*).—An annual, 2-3 ft. high, native of Spain, and also found in most parts of S.W. Europe. The stems and leaves are covered with a whitish silvery down. Leaflets usually 5-6, oblong-lance-shaped, hairy beneath. Flowers in summer, usually dark blue, large, often splashed with white.

Culture &c. as above, and for *L. luteus*. Seeds to be sown annually.

L. venustus.—A downy Californian annual 1½–2 ft. high. Leaflets 9–11, obovate-lance shaped, slightly hairy beneath. Flowers from July to September, deep purple or violet, with a white keel.

Culture &c. as above for *L. luteus*. Seeds to be sown annually.

ADENOCARPUS.—A genus consisting of 8 species of silky, downy, or hairy shrubs, with digitately 3-foliolate leaves and yellow flowers in terminal racemes. Two upper lobes of calyx free; 3 lower more or less connate. Standard petal roundish; wings obovate or oblong; keel much incurved or slightly beaked. Stamens 10, united in one bundle. Pod linear, compressed, with glandular prickles.

Culture and Propagation.—These plants thrive in a mixture of loam, peat, and sand, and are very useful plants for borders or shrubberies, which are brightened by their elegant yellow flowers. Plants may be increased by seeds, layers, or cuttings, the latter being put under a glass in sandy soil in summer and autumn. The species mentioned below are the hardiest in this country.

A. decorticans (*A. Boissieri*).—A beautiful Spanish shrub, somewhat resembling the Common Furze in appearance and habit. The branches, however, are quite free from spines, but are densely clothed with leaves cut into 2–3 foliolate linear leaflets. During the early summer months masses of large golden-yellow blossoms are freely borne, and look very effective against the deep green of the foliage.

Culture &c. as above. It is easily raised from seeds, but as the seedlings do not transplant well, they are best grown on in pots until large enough to transfer to their permanent positions.

A. hispanicus.—A deciduous Spanish shrub 2–4 ft. high, with hairy branches, and 3-foliolate, clustered leaves. Flowers in June, yellow, in crowded racemes.

Culture &c. as above.

A. intermedius.—A deciduous shrub 3–4 ft. high, native of S. Italy and Sicily, with rather shaggy branches. Flowers in May, not crowded on the racemes.

Culture &c. as above.

A. parvifolius.—A deciduous species 3–4 ft. high, native of exposed heaths in

France. Branches smooth. Flowers in May, yellow, not crowded on the racemes
Culture &c. as above.

A. telonensis.—A deciduous native of S. France, 2–4 ft. high. Flowers in June, yellow, not crowded on the racemes.

Culture &c. as above.

LABURNUM (GOLDEN RAIN; GOLDEN CHAIN).—A genus with a few species of ornamental smooth or downy trees or shrubs, with digitately 3-foliolate leaves, inconspicuous stipules, and yellow flowers in terminal racemes. Calyx shortly 5-toothed. Petals free, clawed; standard petal ovate or round; wings obovate; keel incurved, bluntish, shorter than the wings. Stamens 10, united in one bundle. Pod linear, flatly compressed.

Culture and Propagation.—Laburnums thrive in almost any soil and situation, but they are most effective as groups in open spaces. If near large trees or buildings, they soon become ungainly-looking and one-sided. The plants are easily raised from seeds, but there is great variation among them, some having short loose miserable clusters of flowers. The finest varieties—those with very long crowded clusters of bloom—are the best to grow, and they may be increased by grafting or budding on the commoner varieties. In making new plantations it is better to use young plants, as older ones are difficult to transplant and take a long time to recover from the shock to the roots. Fine varieties of Laburnum when in blossom always attract such great admiration that they are often planted as a result in all sorts of positions—suitable and otherwise—to the exclusion of other choice flowering trees and shrubs.

L. Adami (*Purple Laburnum*).—This remarkable tree, 15–20 ft. high, is supposed to be a ‘graft’ hybrid between the purple-flowered *Cytisus purpureus* and the yellow-flowered *Laburnum vulgare*, raised by Jean Louis Adam, from whom it takes its name. The flowers are intermediate in character and colour between the two parents, but sometimes yellow, purple, and intermediate flowers are seen on the same plant—the first two producing seeds, the latter sterile.

Culture &c. as above.

L. alpinum (*Cytisus alpinus*).—*Scotch Laburnum*.—A European tree 15–20 ft.

high, with ovate lance-shaped leaflets, rounded at the base. Flowers in June, yellow, in drooping clusters. *C. fragrans*, *C. hirsutum*, and *C. pendulum* are varieties, the characters of which are indicated in the names. The variety *Alschiingeri* has very long clusters of flowers; *autumnale* flowers in autumn from the end of the current year's shoots; *Parkesi* has very long racemes of deep yellow flowers; *Watereri* has racemes a foot or more in length, and is probably the most beautiful of all.

Culture &c. as above, p. 327.

L. caramanicum.—A beautiful but not well-known shrub 3-4 ft. high, native of Asia Minor. Leaves small, shortly stalked, 3-foliolate. Flowers in June and July, bright yellow, in erect racemes forming a large truss at the ends of the shoots. Grows well in chalky soil.

Culture &c. as above, p. 327.

L. vulgare (*Cytisus Laburnum*).—*Common Laburnum.*—A tree 20-30 ft. high, native of Central and S. Europe. Branches round, whitish; leaflets ovate lance-shaped, downy beneath. Flowers from April to June, bright yellow, in drooping racemes often nearly a foot in length in the best forms.

There are several varieties, among which the best are: *aureum*, with golden-yellow leaves; *Carlieri*, with very narrow leaflets and long racemes; *involutum*, with the leaflets curled so as to form 'rings'; *quercifolium*, with leaflets sinuated and lobed, like a miniature Oak-leaf in outline; *serotinum*, flowers later than most of the others; *monstrosum fastigiatum* is a form with erect flexible branches; and *sessilifolium* is recognised by the absence of leaf stalks.

There is also a form with variegated leaves, which is not particularly attractive and may be regarded merely as a curiosity.

Culture &c. as above, p. 327.

PETTERIA.—This genus has been separated from *Laburnum* and *Cytisus*, and has only one species here described with the characters of the genus:—

P. ramentacea (*Cytisus Weldenii*; *Laburnum ramentaceum*).—A dwarf smoothish shrub, native of Dalmatia, with digitately 3-foliolate leaves, elliptic entire leaflets, and small, blunt or obsolete stipules. Flowers in spring, yellow, in dense terminal erect racemes. Calyx bell-shaped, 3-lobed, ciliated. Standard petal

round; wings and keel oblong, rather straight; keel pouched on each side. Stamens 10, united. Pod broadly linear, rather sickle-shaped, compressed.

Culture and Propagation.—This species will flourish in ordinary good garden soil, and is suitable for massing with other shrubs. Seeds are freely produced, and plants may be readily raised from these when sown either in autumn or spring in cold frames, or out of doors in the milder parts of the country. Layers may also be made in autumn, and any particularly fine varieties may be grafted on seedling stocks of the commoner forms.

GENISTA (Rock Broom).—A genus with about 70 species of smooth or silky, armed or spiny shrubs. Leaves simple or rarely digitately 3-foliolate. Stipules minute or none. Flowers yellow, rarely white, either singly or in clusters at the ends of the branches. Calyx bell-shaped, the upper lobes usually free, the 3 lower united. Standard petal ovate; wings oblong; keel oblong, straight or slightly incurved. Stamens 10, united in one bundle. Pod roundish, ovate, oblong, or linear.

Culture and Propagation.—*Genistas* thrive in any good well-drained garden soil, and are easily increased from seeds. These may be sown as soon as ripe, or in spring, either out of doors for the hardier species, or in cold frames for the more tender ones. The seedlings are pricked out when large enough and given more room to develop, and are ultimately planted in their permanent positions.

As many species begin to show signs of decay after a few years' growth, it is always safe to raise young plants from seeds every two or three years to take the place of any that show signs of weakness.

G. ætensis (*Spartium ætense*).—A native of Sicily and Sardinia, 6-15 ft. high, with few linear silky leaves on the younger twigs only. With the advance of age the leaves drop and the slender green branches have to perform their duties. Flowers from June to August, in great profusion, the bright yellow clusters being in striking contrast to the deep green of the twigs.

Culture &c. as above.

G. anglica (*Needle Furze*; *Petty Whin*).—A prostrate British shrub 1-2 ft. high, with ovate-lance-shaped spiny

leaves. Flowers in early summer (May and June), yellow, in short leafy racemes.

Culture &c. as above.

G. anxantica.—A dwarf spreading species, native of Italy, with ovate elliptic, rather leathery leaves, and a profusion of golden-yellow flowers late in summer.

Culture &c. as above. This is a good plant for massing in the rock garden in warm sheltered positions.

G. aspalathoides.—A pretty dense and compact spiny bush 1–2 ft. high, native of S.W. Europe. During the summer months (in July and August) it bears masses of yellow flowers.

Culture &c. as above. It is a good plant for the rock garden or for furnishing the sides of grassy slopes, banks &c.

G. ephedroides.—A stiffish spiny shrub 2–3 ft. high, native of Corsica and Sardinia. Leaflets 3, smooth, linear. Flowers in summer from June to August, yellow.

Culture &c. as above, p. 328.

G. germanica.—A European species about 18 in. high, with arching stems, and an abundance of bright yellow flowers in summer and autumn.

Culture &c. as above. A good rock garden plant.

G. hispanica.—A native of S.W. Europe, 6–12 in. high or more, with lance-shaped hairy leaves and stiffish branched spines. Flowers from May to July, large, yellow, fragrant, in crowded racemes. *Flore pleno* is a charming double-flowered variety.

Culture &c. as above, p. 328.

G. monosperma (*G. Retama*).—A slender-stemmed twiggy species 2–4 ft. high, native of the Spanish Peninsula. Leaves linear oblong, downy. Flowers in summer, white, silky, in lateral few-flowered racemes which give a charming appearance to the plant.

Culture &c. as above. This fine species is rather too tender for cultivation out of doors in the British Islands except in the mildest parts of the south and west. Even in such places it is safer to plant it in the warmest and most sheltered spots. A good plant for seaside places; grows well in sandy soil.

G. ovata.—A native of Central and S. Europe, 2–4 ft. high, with round, hairy, erect, striped stems, and hairy ovate leaves. Flowers in summer, yellow, in short clusters. This is probably one of

the many forms of *elatior*, referred to under *G. tinctoria* below.

Culture &c. as above.

G. pilosa (*Greenweed*).—A dense prostrate shrub, native of the gravelly heaths in the S. and S.W. of England, with obovate-lance-shaped blunt downy leaves. Flowers in May and June, bright yellow, axillary on short stalklets.

Culture &c. as above. A good plant for dry places in the rock garden.

G. radiata (*Spartium radiatum*).—A native of Central and S. Europe, 1–5 ft. high, with smooth angular branches. Leaflets 3, linear, silky. Flowers in summer (June and July), bright yellow, borne at the ends of the branches.

Culture &c. as above. A good plant for dry soils.

G. ramosissima (*G. cinerea*).—A native of S. Spain about 3 ft. high, with slender twiggy branches. Flowers in July, yellow, in great abundance.

Culture &c. as above.

G. sagittalis.—A distinct species less than 1 ft. high, native of S. Europe, having two-edged, wing-like branches, with ovate lance-shaped leaves, and masses of yellow flowers in May and June, borne in erect racemes at the ends of the shoots.

Culture &c. as above.

G. tinctoria (*Dyer's Greenweed*).—A round-stemmed spineless shrub 1–2 ft. high, native of Britain. Leaves lance-shaped, smoothish. Flowers from July to September, bright yellow, in great profusion. The variety *elatior*, from the Caucasus, grows 4 or 5 ft. high, and bears large panicles of yellow flowers. It is known under many names, and is evidently a very variable plant. The variety *flore pleno* with double flowers is very attractive, and makes a good plant for the rock garden or on banks.

Culture &c. as above.

G. virgata.—A round-branched twiggy species 3–10 ft. high, native of Madeira. Leaves oblong lance-shaped, rather silky. Flowers from April to July, golden-yellow, in racemes at the end of nearly every twig. Occasionally the blossoms are borne a second time in autumn, but never in such great profusion as in the earlier part of the year.

Culture &c. as above. Although a native of Madeira, this species seems to

be perfectly hardy out of doors, at least in the neighbourhood of London.

SPARTIUM (RUSH or SPANISH BROOM).—This genus consists of only one species described below and including the generic characters.

S. junceum (*S. acutifolium*; *Genista juncea*; *Spartianthus junceus*).—A well-known beautiful shrub 6–10 ft. high, native of Mediterranean countries. Branches slender, twiggy, round, and usually without leaves or stipules. Flowers from June to August, large, bright yellow, in erect clusters, and great profusion. Calyx somewhat spathe-like. Standard petal large, round; wings obovate; keel incurved, pointed, longer than the wings. Stamens 10, united in one bundle. Pod elongate, linear, smooth, flat. There is a double-flowered form called *flore pleno*.

Culture and Propagation.—The Spanish Broom will grow well in any poor dry soil in exposed situations, and is useful for borders, shrubberies, or sunny banks. Several fine specimens may be seen on the banks of the Great Western Railway between Slough and Maidenhead. Plants are easily raised from seeds, which ripen in quantity. The seed-pods are best picked just before they begin to open, and if placed in shallow trays in a warm sunny place will soon ripen fully. The seeds may then be sown in the open border, but as a rule the seedlings will not appear until the following spring. They may then be transplanted in mild showery weather, when large enough, and if judiciously placed will form very striking features in the garden. Besides seeds, plants may be raised from cuttings. Shoots of the more or less ripened and flowerless stems may be inserted in sandy soil under a handlight in late summer or autumn and will be well rooted by the following spring.

In spring, before growth commences, old straggling plants may be cut down quite low. This will induce new and strong young growths to spring up from the base, and thus refurnish the plant and give it a better shape and appearance.

ULEX (FURZE; GORSE; WHIN).—A genus containing about a dozen species of sharply spiny shrubs, the leaves of which are reduced to spiny stalks or small scales. Stipules none. Flowers yellow, solitary or in short axillary racemes.

Calyx membranous, coloured, 2-parted. Petals shortly clawed, nearly equal; standard ovate; wings and keel oblong, blunt. Stamens 10, united in one bundle. Pod ovate, oblong, and shortly linear, compressed or swollen.

Culture and Propagation.—The beauty of the Furze when in bloom is very well known. For covering banks, knolls, mounds &c. it is very useful, and requires no cultural skill. It is best to use young plants, as old ones are awkward to handle, and besides do not transplant well. Seeds germinate freely in spring, after having been sown as soon as ripe in autumn, but the special varieties may also be increased by cuttings of the ripened or half-ripened shoots placed under a handlight in late summer or autumn.

U. europæus.—This is the well-known Gorse, Whin, or Furze, seen in such abundance on British commons, banks, &c. It grows 2–3 ft. high, and has the spines sometimes furnished with minute 1-foliolate hairy leaves. Flowers in February and March, yellow, $\frac{3}{4}$ in. long, odorless, with black hairs on the calyx. *Flore-pleno* is a beautiful double-flowered variety, almost hiding the branches, with its wealth of bloom. *Strictus* (known as the Irish Furze) has stiffish erect branches. In Ireland the young shoots of Furze are often chopped up fine and given to horses.

Culture &c. as above.

U. nanus (*Cat Whin*; *Tam Furze*).—Also a native of the British Islands 1–3 ft. high, with drooping branches, and spines $\frac{1}{2}$ – $1\frac{1}{2}$ in. long. Flowers from July to November, $\frac{1}{2}$ in. long, followed by pods which persist till the following year. The variety *Galli* has ascending branches, and stiff spines longer than those of *nanus* proper.

Culture &c. as above.

CYTISUS (BROOM).—A genus with less than 40 species of shrubs, rarely spiny. Leaves 1–3-foliolate, or absent. Flowers yellow, purple, or white. Calyx more or less 2-lipped. Standard petals almost round, or ovate; wings obovate, or oblong; keel straight or incurved, obtuse or scarcely pointed. Stamens 10, united. Pod flat, compressed, oblong or linear, smooth or hairy.

Culture and Propagation.—The hardy *Cytisus* are ornamental shrubs, and grow well in ordinary garden soil, being useful in groups, borders, or shrubberies.

They are mostly raised easily from seeds sown in the open air as soon as ripe, or in cold frames in the case of the more tender varieties. The seedlings may be transplanted in spring to their permanent positions. The plants may also be increased by layers; or the choicer varieties may be grafted on the commoner sorts, but this is not recommended. Cuttings of the more or less ripened and flowerless shoots will root in fine sandy soil if inserted about August and September in a shaded spot and covered with a handlight. In spring when well rooted they may be transplanted. To secure the finest effects the plants should be grown in bold masses. As their roots strike down rather deeply into the soil these plants are particularly well suited for growing in dry sandy soils in which other shrubs will not thrive. As they do not however retain their vigour and floriferousness for many years, it is as well always to have a stock of young plants at hand.

C. albus (*White Spanish Broom*).—A round-stemmed, twiggy shrub, 6–10 ft. high, native of the Spanish Peninsula. Leaves sessile, 3-foliolate, with linear oblong silky leaflets. Flowers about Whitsuntide, white, in long clustered racemes, in great profusion. The variety *incarnatus* has wine-red flowers, and *multiflorus* is a free-flowering form of the type.

Culture &c. as above.

C. Ardoini.—A pretty rock plant, about 4 in. high, native of the Maritime Alps, with stiffish decumbent stems, springing from a knotted and twisted stock. Leaflets obovate, hairy, silky when young. Flowers in spring, bright yellow, 1–6 in the axils of each leaf.

Culture &c. as above. This charming little Broom flourishes in warm and dry positions in the rock garden, and is very effective during April and May when covered with masses of bright yellow blossoms.

C. austriacus.—A round-stemmed twiggy shrub 2–4 ft. high, native of Austria, and covered with close-pressed stiffish hairs. Leaflets spindle-shaped. Flowers in June, yellow. There is a variety called *leucanthus* with soft whitish or creamy-yellow blossoms.

Culture &c. as above.

C. biflorus (*C. elongatus*).—A spreading twiggy Hungarian bush, about 3 ft.

high. Leaves 3-foliolate, with close-pressed hairs beneath. Flowers in May, bright yellow, about 1½ in. long.

Culture &c. as above. This is a very variable species, and is known under many other names, such as *camariensis*, *caucasicus*, *ruthenicus*, *serotinus*, *uralsensis* &c.

C. capitatus.—A hairy-branched European shrub, 2–4 ft. high. Leaflets ovate-elliptic, hairy. Flowers in June, yellow, numerous.

Culture &c. as above. This species is also known as *C. calycinus*.

C. hirsutus.—A decumbent shrub, with round twiggy branches, native of Europe. Leaflets obovate, hairy beneath. Flowers in June, yellow, clustered on very short stalklets.

Culture &c. as above.

C. kewensis.—This is a charming hybrid Broom raised as a chance seedling at Kew, between the small yellow-flowered *C. Ardoini* and the tall white-flowered *C. albus*. It has a trailing habit, resembling in that respect *C. Ardoini*, and during the later spring months produces its pale creamy-yellow blossoms in great profusion.

Culture &c. as above. To keep this beautiful plant quite true in character it is safer to increase it by means of cuttings, as plants raised from seeds are likely to vary a good deal, and would probably revert to one or the other parent eventually. For trailing over the surface of beds, in the rock garden, or sunny banks, this hybrid is a valuable acquisition.

C. monspessulanus (*Genista candicans*; *G. triangularis*; *G. triquetra*).—A native of S. Europe 2–4 ft. high, with triangular decumbent stems, and simple or 3-foliolate leaves; leaflets ovate lance-shaped, hairy. Flowers in summer, yellow, in short terminal racemes.

Culture &c. as above.

C. nigricans.—A downy Austrian shrub, 3–6 ft. high, with round twiggy branches. Leaves 3-foliolate, with elliptic leaflets. Flowers in June, yellow, in erect racemes.

Culture &c. as above.

C. præcox.—A beautiful flowering shrub 8–10 ft. high, with a free and graceful habit. It is a hybrid between the yellow-flowered *C. purgans* and the white-flowered *C. albus*, and first appeared

more than thirty years ago. It makes a dense and compact growth, and the bright green slender twigs give it an evergreen character when not in blossom. From the middle of April till about the middle of May, the young shoots, often nearly 2 ft. long, are literally covered with masses of pale primrose-yellow flowers, which however emit a rather powerful and not particularly pleasant odour.

Culture &c. as above. The only way to keep this hybrid true to character is to increase it by cuttings inserted in sandy soil about August or September, as recommended above. It usually ripens seeds freely, but like many other plants of hybrid origin, the chances of obtaining the true variety from seeds are very remote.

C. purpureus (*Purple Broom*).—A beautiful wiry branched trailing shrub, with oblong leaflets, and purple flowers in May, in great abundance. Native of Eastern Europe.

Culture &c. as above. It is often grafted on standards of the *Laburnum* to show its weeping habit. Among rocks and boulders the branches look very effective when in bloom. There is a white-flowered variety called *albus*, and a pretty yellow-flowered one known as *ratisbonensis*.

C. scoparius (*Common Broom*).—A native shrub 2–10 ft. high, with slender angular hairy branches. Leaves 3-foliolate, with oblong leaflets. Flowers from April to July, yellow, solitary. There are several forms of this species, but the most important and beautiful is *andreaeus* (*Genista andreaea*), in which the wings of the yellow flowers are of a rich purple-brown. This variety is much grown as a pot plant, and is gently forced into bloom in greenhouses in early spring. Other varieties are *pendulus*, with a weeping habit; and *sulphureus*, with pale yellow sulphur-coloured blossoms.

Culture &c. as above. This showy shrub will flourish under almost any circumstances, except in wet, cold and boggy situations.

C. sessilifolius.—A smooth, round-branched shrub 4–6 ft. high, native of S. Europe. Leaflets 3, ovate. Flowers in May, yellow, in short erect racemes.

Culture &c. as above.

ONONIS (**REST HARROW**).—A genus with about 60 species of smooth, downy or hairy, often clammy annual, biennial, or

perennial herbs or undershrubs. Leaves usually pinnately 3-foliolate, with the veins running into teeth on the edges. Stipules adnate to the leaf stalk. Flowers rose, yellow, or white, in axillary solitary or 2–3-flowered racemes. Calyx tube short with nearly equal lobes. Standard petal nearly round, with a short claw; wings obovate oblong; keel incurved, beaked, rarely blunt. Stamens 10, united, or the upper one rarely free. Pod oblong or linear, inflated or round.

Culture and Propagation.—The Rest Harrows may be utilised for covering rough banks and parts of the rockery. They grow in any soil, and are easily increased by seeds, or division of the roots in early autumn or spring. The seeds may be sown as soon as ripe in warm sheltered spots out of doors, or in cold frames, and the seedlings may be transplanted the following spring. The shrubby kinds may also be increased by cuttings of the fairly well-ripened shoots inserted in sandy soil under a handlight about August and September.

Both *O. spinosa* and *O. reclinata* are British plants, usually found on dry pastures, fields, cliffs &c., and although pretty, perhaps hardly worth cultivating when there are so many better plants.

O. aragonensis.—A pretty half-hardy shrub 1–2 ft. high, with smooth 3-foliolate leaves composed of roundish serrate leaflets. The almost stalkless flowers appear from May to July on a leafless raceme, the yellow blossoms being usually in pairs.

Culture &c. as above. This species is fairly hardy in the neighbourhood of London, and ripens seeds freely.

O. fruticosa.—A handsome shrub 1–2 ft. high, native of S.W. Europe. Leaflets 3, sessile, smooth, lance-shaped, shining, unequally serrated. Flowers in summer, purple, three on a stalk.

Culture &c. as above. Increased by seeds or cuttings.

O. Natrix.—A S. European perennial 1½–2 ft. high, clothed with a clammy pubescence. Leaflets 3, oblong, serrated at the apex. Flowers in summer, yellow, veined with red.

Culture &c. as above. Increased by seeds or division.

O. rotundifolia.—A pretty rather shrubby perennial, 1–1½ ft. high, native of South Europe. Leaflets 3, obovate,

roundish, toothed. Flowers in summer, rosy, three on a stalk.

Culture &c. as above. Increased by seeds or cuttings.

O. viscosa. — A handsome annual with downy clammy stems, 1½–3 ft. high. Leaflets 3, toothed, the middle one largest. Flowers in summer, yellow, in long spikes, the back of the standard striped with purple.

Culture &c. as above. Being an annual from S. Europe, the seeds of this species may be sown in cold frames in autumn or spring, afterwards transplanting the seedlings to their flowering positions. Or they may be sown during April and May in the open border where the plants are to bloom, thinning the seedlings out if too close together.

PAROCHETUS (SHAMROCK PEA).—

A genus having only one species:—

P. communis.—An elegant creeping perennial about 3 in. high, native of the Himalayas. The stems, which root at the joints, have 3-foliolate Clover-like leaves, and during October and November the cobalt-blue Pea-like blossoms are produced either singly or 2 or 3 together in the axils of the leaves.

Culture and Propagation.—The Shamrock Pea is best grown in warm sunny parts of the rockery in well-drained soil. Owing to the late period of blooming, the beautiful blue flowers are often injured by frost, and in cold localities the plants would look better grown in pots in cold frames or a cool greenhouse. Propagation is effected by dividing the rooting stems in spring, or by sowing the seeds at the same period in gentle heat.

MEDICAGO (LUCERN; MEDICK).—A

genus with 40 species of herbs, only one of which is worth growing. Flowers yellow or violet, one or more on a stalk. Calyx shortly toothed or lobed. Petals free from the stamen-tube; standard obovate or oblong, contracted at the base; wings oblong, longer than the obtuse keel. Stamens 10, upper one free. Pod spirally sickle-shaped, or often shell-like, unarmed or spiny.

M. falcata.—A native prostrate perennial with stems 2–4 ft. long. Leaflets 3, oblong, toothed at the apex, entire at the base. Flowers in summer, usually pale yellow, but sometimes violet or green, in short close axillary racemes.

Culture and Propagation.—This species thrives in any soil, and is suitable for banks, slopes, or rough parts of the rock garden. It may be increased by seeds sown in the open border when ripe, or in spring, or the plants may also be increased by division in early autumn or spring.

TRIFOLIUM (TREFOIL; CLOVER).—

A genus containing 150–200 species of annual or perennial herbs, with digitately 3-, rarely 5–7-foliolate leaves, with stipules adnate to the stalks. Flowers in spikes, heads, or umbels, rarely solitary. Calyx teeth or lobes nearly equal. Petals often withering, long-clawed, or the 4 lower ones more or less adnate to the stamens; standard oblong or ovate; wings narrow, longer than the blunt keel. Stamens 10, upper one free or rarely united at the middle with the others. Pod oblong or nearly round, or obovate-compressed.

Culture and Propagation.—The Trefoils are not particularly well-known flower garden plants, but a few of them are useful for creeping about in the rockery or on the margins of borders. They grow in almost any garden soil, and may be increased by division in autumn or spring, or from seed sown when ripe in the open border.

T. alpestre (Owl-headed Clover).—A pretty species 6–12 in. high, from the European Alps and W. Asia. Leaflets lance-shaped, leathery, ciliate toothed; stipules narrow, nearly sessile. Flowers in June and July, purple. Petals united.

Culture &c. as above.

T. fimbriatum.—A N. American species with long thick prostrate stems. Leaflets oblong or slightly wedge-shaped, 1 in. or more long, conspicuously fringed with bristly teeth. Flowers in autumn, purple; calyx teeth spiny.

Culture &c. as above.

T. fucatum.—A Californian annual 6 in. high. Leaflets roundish wedge-shaped, sharply toothed, thickish; stipules large, entire, abruptly pointed. Flowers in June, creamy-white mixed with red.

Culture &c. as above. Sow seeds annually in warm spots.

T. hybridum (Alsike or Bastard Clover).—A European species with flexuose stems 2–10 in. long. Leaflets obovate or oblong, ½–1½ in. long, toothed;

stipules oblong with triangular tips. Flowers from June to August, white or rosy, in heads about 1 in. in diameter.

Culture &c. as above.

T. incarnatum (*Crimson Clover*).—A pretty S. European annual 1 ft. high, with rather slender hairy stems. Leaflets broadly obovate or obovate, $\frac{3}{4}$ –1½ in. long. Flowers in June and July, bright crimson, $\frac{1}{2}$ in. long; calyx hairy.

Culture &c. as above.

T. Lupinaster (*Bastard Lupine*).—A Siberian species 1–1½ ft. high. Leaves unstalked; leaflets 5, linear lance-shaped, sharply toothed and pointed; stipules broad, pointed. Flowers in summer, purple, large, wings and keel paler than the standard. There is a white form called *albiflorum*.

Culture &c. as above.

T. olympicum.—An erect hairy-stemmed species 1 ft. high, native of Mt. Olympus. Leaflets hairy, elliptic-lance-shaped, entire, stipules awl-shaped, sheathing. Flowers in July, yellowish, with a very long standard, calyx hairy.

Culture &c. as above.

T. reflexum (*Buffalo Clover*).—A handsome, more or less decumbent N. American annual, with stems 1–1½ ft. long. Leaflets obovate or obovate-oblong, crenulate serrate; stipules leafy, pointed. Flowers from April to June, with broadly ovate, rosy-red standard, and white wings and keel.

Culture &c. as above.

T. repens purpureum (*Four-leaved Shamrock*).—A variety of the common white Clover 3–5 in. high, with brown or purplish leaves having a broad purple spot on the under side of the leaflets. Flowers during summer, small, white, slightly fragrant.

Culture &c. as above.

T. rubens.—A native of Central and S. Europe 1 ft. high. Leaflets long narrow; stipules large. Flowers in summer, carmine or purple-red, in large ovoid heads.

Culture &c. as above.

T. spadicum (*Brown Clover*).—A European species 6 in. high. Leaflets oblong-ovate, toothed; stipules leafy pointed. Flowers in summer, yellow, standard slightly brownish, obovate.

Culture &c. as above.

T. uniflorum.—A tufted creeping Syrian species with very short stems. Leaflets 3, ovate, pointed, toothed, nerved; stipules sheathing, long pointed. Flowers in June and July, reddish, in thick ovoid heads on long stalks.

Culture &c. as above.

ANTHYLLIS (*KIDNEY VETCH*).—A genus with 20 species of herbs or undershrubs usually with pinnate leaves, rarely reduced to the terminal leaflets. Stipules small, or none. Flowers usually in axillary heads or clustered at the ends of the branches. Calyx tubular or inflated, 5-toothed. Petals nearly equal, long-clawed; standard ovate, abrupt or 2-auricled at the base; wings ovate, blunt; keel smaller than the wings, incurved, bluntish, swollen at each side. Stamens 10, usually united. Pod ovoid, or shortly linear, falcate or curved.

Culture and Propagation.—When in bloom the Kidney Vetches are pretty plants, and look well in the rock garden in sunny positions, and in usually well-drained warm soil. The annual kinds may be raised from seeds sown in the open about April. The perennials may also be raised in the same way, or from cuttings in sandy soil under a glass during the later summer months. Division of some kinds may also be practised in autumn or spring.

A. Barba-Jovis (*Jupiter's Beard*).—A downy Spanish shrub 4–8 ft. high. Leaflets 9–13, oblong-linear. Flowers in March, pale yellow, numerous.

Culture &c. as above. Increased by seeds or cuttings.

A. erincea (*Erinacea hispanica*).—A distinct spiny almost leafless species 6–12 in. high, native of Spain. Leaves few, oval or oblong. Flowers in April, bluish-purple.

Culture &c. as above. Increased by seeds or division. Requires a warm sheltered position on the rockery.

A. Hermanniae (*Cytisus græcus*).—A shrubby Corsican species 2–4 ft. high, with almost stalkless simple or 3-foliolate leaves, more or less downy. The yellow flowers appear in April in the axils of the upper leaves.

Culture &c. as above. Increased by seeds or cuttings.

A. montana.—A pretty tufted silky and hoary rock plant, 3–6 in. high, native

of the Alps. Leaflets numerous, oval-oblong, acute, small, entire. Flowers in June, pink or purple, in dense heads with a leafy involucre as in the variety *atro-rubens*.

Culture &c. as above Increased by seeds or division.

A. Vulneraria (*Common Woundwort*). A pretty native perennial with silky stems 6-18 in. high, and pinnate leaves having 2-6 pairs of narrow oblong leaflets $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long. The flowers appear from June to August and are usually yellow in colour, but sometimes white as in the variety *alba*, or pink, or red. The variety *Dilleni* has creamy-coloured flowers with red tips.

Culture &c. as above. The common Woundwort is found growing naturally on dry rocky banks, and may be utilised for covering dry bare places in the rock garden.

SECURIGERA (AXE WEED; HATCHET VETCH).—A genus with only one species described below:—

S. Coronilla (*Coronilla Securidacea*). A rather pretty S. European annual 1 ft. high with oddly pinnate leaves and entire leaflets; stipules small, membranous. Flowers in July, yellow, nodding, at the tips of the axillary peduncles; petals free from the stamen tube; standard nearly round; wings oblique oblong; keel incurved, somewhat beaked. Stamens 10, upper one free. Pod linear, falcate, pointed, flatly compressed.

Culture and Propagation.—This species grows in ordinary soil, and requires only to be sown every spring where it is to bloom. Warm sunny places suit it best, either in the rockery or border.

DORYCNIUM.—A genus with about 6 species of pretty smooth, downy or hairy herbs or undershrubs. Leaves 4-5-foliolate. Flowers in heads or rather umbellate, numerous. Calyx rather bell-shaped, lobes nearly equal. Petals free from the stamen tube; standard oval-oblong, contracted into a claw at the base; wings oboval-oblong, larger than the incurved, bluntnish swollen keel. Stamens 10, upper one free. Pod oblong or linear, terete, or swollen.

Culture and Propagation.—These plants are easily grown in rather dry soil, and readily come from seeds sown outside either as soon as ripe, or in spring, afterwards transplanting the seedlings or

thinning them out to allow sufficient space to develop properly. They may be grown in the rock garden in warm exposed situations.

D. hirsutum (*Lotus rectus*).—A hoary plant 1-2 ft. high, native of S. Europe. Leaves sessile; leaflets ovate, lance-shaped or obovate. Flowers in July, whitish, or pale red, large, in many-flowered heads.

Culture &c. as above.

D. suffruticosum (*Lotus Dorycnium*). A pretty S. European shrub 2-3 ft. high. Leaflets and stipules oblong lance-shaped, acute. Flowers in June, white, with a reddish keel.

Culture &c. as above. Other species met with are *D. herbaceum* and *D. latifolium*, both from S. Europe and with white flowers, and *D. rectum* from the same region with small rose-coloured ones.

LOTUS (BIRD'S FOOT TREFOIL).—A genus with 50-100 species of smooth, silky or hairy herbs or undershrubs. Leaves 4-5-foliolate. Stipules minute, tubercular, or none. Flowers on an axillary stalk, usually several in an umbel. Calyx lobes nearly equal. Petals free from the stamens; standard obovate roundish, or ovate, pointed, contracted into a claw at the base; wings obovate; keel incurved or inflexed, beaked, swollen at the sides. Stamens 10, upper one free. Pod oblong or often linear, straight or curved, round, swollen or flatly compressed.

Culture and Propagation.—The species described below is the only one worth growing in the outdoor garden. It thrives in ordinary soil, and is easily raised from seeds sown in the open air as soon as ripe or in spring. Well suited for carpeting parts of the rockery.

L. corniculatus.—This is a British plant often seen in pastures, meadows &c. Leaflets obovate, acute, entire. Flowers in summer and autumn, bright yellow, fading to orange, 4-10 on a stalk; standard petal striped with red in front. The double-flowered variety is an improvement on the type.

PSORALEA.—A large genus of herbs, shrubs or undershrubs usually with leaves composed of 3-5 leaflets, and having the stipules adhering to the stalk. The flowers are borne in heads, spikes, racemes or fascicles, rarely solitary, and purple,

blue, rosy or white in colour. Calyx lobes nearly equal, the 2 upper ones often united. Petals about as long as or shorter than the keel; standard ovate or round, contracted into a claw, or furnished with small inflexed auricles; wings oblong, somewhat sickle-shaped; keel blunt, incurved. Pod ovate, indehiscent.

P. glandulosa.—A rather pretty Chilean shrub 2-4 ft. high, with ternate leaves composed of ovate lance-shaped tapering leaflets. The white flowers, tinged with blue, are borne from May to September in spiked racemes, issuing from the axils of the upper leaves.

Culture and Propagation.—This species is rarely met with, but it is fairly hardy at Kew in warm positions and would no doubt be quite hardy in the mildest parts of the south and west. It will grow well in ordinary good garden soil, and may be increased by cuttings of the plump shoots in early summer, placed under a handlight or in a cold frame or greenhouse.

There are several herbaceous species to be met with chiefly in botanic gardens, viz. *bituminosa*, from South Europe; *macrostachya*, from California; and *Onobrychis* and *physodes* from the more northern parts of America.

AMORPHA (BASTARD INDIGO).—A genus with 8 species of smooth or downy shrubs or undershrubs. Leaves oddly pinnate with numerous glandular-dotted leaflets. Stipules small or none. Flowers densely spicate, racemose, terminal. Calyx lobes almost equal. Standard ovate, erect, contracted into a claw; wings and keel absent. Stamens 10, united. Pod short, long, sickle-shaped or crescent-shaped.

Culture and Propagation.—These plants thrive in ordinary garden soil, but require shelter in bleak localities. They may be increased by layers or cuttings, the latter being taken off at a joint and inserted in a sheltered place in sandy soil in autumn, allowing them to remain about a year. They should be protected with handlights during the winter months. Suckers, which are freely produced, may also be used to increase the plants.

A. canescens (Lead Plant).—A hoary-looking plant 3 ft. high, native of Missouri. Leaflets ovate-elliptic, sharply pointed. Flowers in July, dark blue.

Culture &c. as above.

A. fruticosa.—A smooth or slightly hairy species 6 ft. high, native of Carolina. Leaflets elliptic-oblong. Flowers in June and July, very dark bluish-purple or violet, with conspicuous yellow stamens. In catalogues will be found numerous so-called varieties of this species, but it is very difficult to distinguish one from another. Indeed in the Kew Handlist of Trees and Shrubs as many as 15 distinct synonyms are given for this species.

Culture &c. as above.

PETALOSTEMON (PRAIRIE CLOVER).—A genus with 14 species of usually perennial, glandular, dotted herbs with oddly pinnate leaves. Stipules minute, bristly. Flowers in heads or terminal spikes, or opposite the leaves, often stalked. Calyx lobes nearly equal. Standard, with a free slender claw, heart-shaped or oblong, concave or cup-like. Stamens 5, united at the base. Pod, including the calyx, membranous.

Culture and Propagation.—The following species are best known but are not very much cultivated. They thrive in sandy loam with a little peat or leaf mould, and may be increased by dividing the rootstocks in spring.

P. candidus.—A N. American perennial, 1 ft. high. Leaflets 7-9, lance-shaped or linear oblong. Flowers in July, white, in oblong or cylindrical heads.

Culture &c. as above.

P. violaceus.—Also a N. American perennial 1 ft. high, leaflets 5, narrow, linear. Flowers in July, rosy-purple, in globose, ovoid, or oblong-cylindrical heads.

Culture &c. as above.

INDIGOFERA (INDIGO).—A genus with over 200 species of herbs or undershrubs. Leaves oddly or evenly pinnate, rarely digitately 3-foliolate. Flowers in axillary racemes or spikes. Calyx lobes small, nearly equal. Standard ovate or roundish; wings oblong, slightly cohering to the straight blunt or pointed keel. Stamens 10, upper one free. Pod globose, oblong or linear, straight, arched, or rarely crosier-like.

I. decora.—A pretty evergreen shrub 1-3 ft. high, native of China and Japan. The pinnate leaves are composed of 2-6 pairs of bluntly ovate mucronate leaflets,

and the reddish flowers are produced during the early summer months in crowded racemes. The variety *alba* has white flowers.

Culture and Propagation.—This species was once generally cultivated in greenhouses, but it has been proved fairly hardy out of doors in the neighbourhood of London. It grows better, however, in the milder parts of the south and west in warm and sheltered places. It will grow in loamy soil and leaf mould, and may be increased by seeds and cuttings in the same way as *I. gerardiana*.

I. gerardiana (*I. floribunda*).—A pretty Himalayan low branching shrub with shortly stalked pale grey-green leaves, glaucous and hoary beneath. Flowers in July, purple-pink, 10-20 on an erect raceme. Seeds are ripened freely.

Culture and Propagation.—This may be grown as a bush or against a wall, and in bleak districts may require protection in winter. It thrives in loamy soil with leaf mould, and is easily raised from seeds sown under glass; or may be increased by cuttings of the young shoots in sandy or peaty soil. It is an excellent plant for massing boldly in beds on the grass.

GALEGA (GOAT'S RUE).—A genus with 3 species of smooth, erect, ornamental perennial herbs. Leaves oddly pinnate; leaflets entire, veined. Stipules somewhat arrow-shaped. Flowers in axillary and terminal racemes. Calyx teeth nearly equal. Standard petal obovate-oblong, with a short, narrow claw; wings oblong, slightly adhering to the somewhat incurved, blunt keel. Stamens 10, united. Pod linear, roundish, pointed.

Culture and Propagation.—Galegas like a rich, loamy soil and sunny situations, and will flower year after year if left undisturbed. It is advisable, however, either to divide them, say, every third or fourth year, or to give them fresh soil. They may be increased by dividing the rootstocks in early autumn or in spring, the latter season being perhaps better on the whole; or by sowing seeds in the open border in spring. Cuttings of the non-flowering shoots may be inserted in cold frames during the summer months and kept close for a time.

Galegas are very useful and ornamental plants for massing in the flower border or even in beds by themselves.

G. officinalis (*Common Goat's Rue*).—A native of South Europe, 3-5 ft. high. Leaves lance-shaped, smooth, sharply pointed; stipules broadly lance-shaped. Flowers in summer, blue, in dense clusters. The variety *albiflora* (or *G. persica*) is a very handsome plant with white flowers, and *bicolor* has white and blue flowers.

Culture &c. as above. By pinching off the withering flowers and thus preventing the development of seeds, the plants often flower a second time in autumn; but this is a strain on them.

G. orientalis.—A Caucasian perennial, 2-4 ft. high, with creeping roots and simple flexuous stems. Leaves ovate, pointed, smooth; stipules broadly ovate. Flowers in summer and autumn, blue, in more or less erect clusters.

Culture &c. as above.

WISTARIA (GRAPE-FLOWER VINE; SHOES AND STOCKINGS).—A genus with 4 or 5 species of high-climbing, deciduous shrubs, with oddly pinnate leaves, small stipules, and drooping terminal racemes. The 2 upper teeth of the calyx short and somewhat united; the 3 lower ones longer. Standard petal large; wings oblong sickle-shaped, usually free from the blunt, incurved keel. Stamens 10, the upper one free or united with the others near the middle. Pod elongated, alternately swollen and constricted.

Culture and Propagation.—Wistarias—especially the common one—grow in almost any soil, and flower profusely for many years without the slightest attention to roots or soil. They are easily increased by layering the young shoots in summer, and cutting them away the following spring. Cuttings will root only with great difficulty, and grafting a shoot on to the roots is sometimes practised; but neither of these methods is an improvement on the easier operation of layering.

For covering the walls of houses, arbours, trellises &c. the value of the *Wistaria* is well known. Grown as a standard with the branches creeping or trained to a framework, the plants look very effective on lawns when clothed with their weeping trusses of delicate blossoms. Of the species described below, the common *Wistaria chinensis* is undoubtedly the finest and most useful, and it is never likely to be supplanted as one of the most ornamental woody climbers in cultivation.

If uncared for, the branches and stems in a few years become inextricably tangled. To prevent this they should be looked over carefully once a year, cutting out such branches as are not wanted, and training others to fill up gaps as may be required.

W. brachybotrys.—A tortuous Japanese shrub 3–5 ft. high. Leaflets truncate or rather heart-shaped at the base, ovate lance-shaped, pointed, silky, hoary on both sides. Flowers in April, violet-purple, in short erect or loosely spreading clusters.

Although known for many years this is still a very rare plant, and only small specimens are to be met with in cultivation. There is a white-flowered variety *alba* also known.

Culture &c. as above.

W. chinensis (*W. sinensis*; *W. consequana*; *Glycine chinensis*; *G. sinensis*). *Chinese Kidney Bean Tree.*—A beautiful Chinese climbing shrub, with ovate-pointed leaflets in opposite distant pairs, covered with a thin silky down. Flowers from April to June, before the leaves are fully developed, pale purple, in long conical clusters, and in great abundance. There is a pure white-flowered variety called *alba*, and a double-flowered form, *flore pleno*; *macrobotrys* has white flowers tinted with bluish-purple, in very long clusters; and *variegata* has silver and green foliage, but it and *flore pleno* are not particularly handsome.

Culture &c. as above. This is one of the few cases where the botanical name has found popular favour, and the *Wistaria* is probably one of the best known plants in cultivation. It is invaluable for covering houses and buildings of all kinds, and if the branches are trained round the various sides, thus securing different aspects, the period of flowering can be considerably lengthened. Thus the shoots on a north wall will be in bloom 2 or 3 weeks even after those on a south wall have faded. In August and September again, it is not unusual for healthy plants to come into blossom anew, but the flowers are not in such great profusion as in the earlier part of the year.

W. frutescens (*Glycine frutescens*; *Thyrsanthus frutescens*).—*American Kidney Bean Tree.*—A handsome deciduous N. American climber. Leaflets 9–13, 1 in. long, ovate lance-shaped or oblong. Flowers later than *W. chinensis*, dark blue,

violet-tinted, in clusters 4–6 in. long. *Magnifica* is an improved form with flower racemes over 1 ft. long. There is also a variety *alba* with white flowers, but otherwise similar to the type.

Culture &c. as above.

W. japonica.—A smooth Japanese shrub. Leaflets shortly stalked, ovate lance-shaped, blunt or acute. Flowers in summer, white, in simple nodding racemes. This species may be grown as a bush, in which state it shows little tendency of a climbing nature. It is also known as *Millettia japonica*.

Culture &c. as above.

W. multijuga (*W. grandiflora*).—A beautiful Japanese species with pinnate leaves, and numerous elliptic-ovate, pointed leaflets. Flowers in summer, pale lilac-purple, with purple wings and keel, individually smaller than those of *W. chinensis*, but in racemes often 2–3 ft. long.

Culture &c. as above.

ROBINIA (LOCUST TREE).—A genus with 5 or 6 species of clammy or bristly deciduous trees or shrubs, with oddly pinnate leaves, bristly or spiny stipules, and flowers in axillary racemes. Calyx teeth short, broad. Standard petal large, reflexed; wings sickle-shaped, oblong, free; keel incurved, blunt. Stamens 10, the upper one usually free to the base, or united with the others midway. Pod linear, flatly compressed.

Culture and Propagation.—*Robinias* grow well almost everywhere, except in stagnant wet soil, and from the spring to late autumn are very ornamental in appearance. They may be increased by layers when obtainable, or the rarer kinds by grafting or budding on *R. Pseudacacia*. Seeds will also germinate fairly well, especially if soaked in hot water for a few hours previous to sowing. Cuttings of the roots may also be inserted in sandy soil in gentle bottom heat in the early spring months.

R. dubia (*R. ambigua*; *R. echinata*). A supposed hybrid between *R. Pseudacacia* and *R. viscosa*. It is a pretty tree about 25 ft. high, with ovate leaflets. Flowers from June to August, pale rose, sweet-scented, in loose drooping racemes, followed by brown pods thickly beset with prickles.

Culture &c. as above. This is also

known as *bella-rosea*, and is regarded as a variety of *R. Pseudacacia*.

R. hispida (*Rose Acacia*).—A beautiful N. American shrub 5-15 ft. high, with more or less bristly branches and stalks. Leaflets 11-18 on a rachis, smooth, ovate, or oblong ovate, tipped with a long bristle. Flowers in early summer, deep rose, large, scentless, in drooping racemes. Pods glandular hairy. The variety *macrophylla* has larger ovate roundish leaflets, and smooth branches and flower stalks without prickles, a fact which has also earned for it the name of *inermis*.

Culture &c. as above. This species is generally grafted on stocks of *R. Pseudacacia*, but it may also be increased by root cuttings. Although it flowers profusely, it rarely ripens any seeds in the British Islands. Plants only 2-4 ft. high flower well.

R. neo-mexicana.—This beautiful small tree or large shrub is a native of Colorado, New Mexico, and Arizona, and sometimes attains a height of 20-25 ft. in a wild state. It has not been many years in cultivation, but has proved to be quite hardy, and there are now specimens at Kew about 15 ft. or more high. The young shoots and the under surface of the young leaflets are covered with brownish hairs, while the fully developed oblong leaflets, each about $1\frac{1}{2}$ in. long, are of a soft bluish-green on the upper surface. The pretty deep rose-coloured flowers appear during the summer months in short drooping racemes about 6 in. long. Seeds are ripened freely, and are enclosed in pods covered with bristly brown hairs.

Culture &c. as above.

R. Pseud-acacia (*False Acacia*; *Common Locust*).—A handsome, hardwooded N. American tree, 30-60 ft. high, with naked branches. Leaflets 9-18, oblong ovate or elliptic. Flowers in April and May, white, fragrant, in slender, loose, drooping clusters, 3-5 in. long. Pods smooth. The first plant of the Common Locust introduced to Europe in 1637 still exists in the Jardin des Plantes at Paris, but the main branches and trunk have been much broken, not unnaturally after more than 260 years.

There are many varieties, such as:—

Bessoniana, a compact, round-headed tree with thornless branches.

crispa, with nearly all the leaflets waved or curled.

Decaisneana, with bright rosy-pink flowers.

fastigiata, similar in growth to the Lombardy Poplar.

inermis, small-growing, round-headed bush, usually grafted on upright stems of the Common Locust, and often seen growing in small villa gardens.

macrophylla, leaves long, leaflets broad.

microphylla, leaves small, leaflets narrow.

monophylla, leaves reduced to a single leaflet or sometimes two.

monstrosa, leaves large and twisted.

pendula, shoots slightly drooping.

procera, tall, strong-growing.

semperflorens, lasts in flower throughout summer.

sophoraefolia, leaves large, like those of *Sophora japonica*.

stricta, a variety with a tendency to grow erect.

tortuosa, branches curiously twisted.

umbraculifera, leaflets ovate; branches much crowded, smooth; head rounded.

The characters of other varieties such as *aurea*, *revoluta*, *angustifolia elegans*, *linearis*, are indicated by the names.

Culture &c. as above. The False Acacia is one of the most graceful hardy trees grown; not so much for its drooping masses of white flowers, but for the light and feathery appearance of its soft green luxurious foliage. For large gardens and parks it is very valuable, and although perfectly hardy, should always be planted in spots sheltered from tempestuous winds. This is necessary chiefly because of the brittleness of the wood, which in old trees especially is readily rent by violent storms. Seeds are ripened freely.

R. viscosa (*R. glutinosa*).—*Clammy Locust*.—A N. American tree 20-40 ft. high. Leaflets 11-15, ovate and oblong, blunt, or slightly cordate at the base, paler and downy beneath, tipped with a short bristle. Flowers in May and June, rosy, in crowded, roundish, erect racemes. Pods glandular, viscid.

Culture &c. as above. Although not such a free grower as the False Acacia, the Clammy Locust is nevertheless a desirable ornamental tree. It is easily recognised not only by its rosy flowers but also by the clamminess of the young shoots and leaf stalks. It ripens seeds freely.

NOTOSPARTIUM.—A genus containing only the one species here described with the generic characters:—

N. Carmichaeliae.—A very interesting and rather ornamental tree, native of New Zealand. It grows about 20 ft. high in well-favoured localities and is easily recognised by its slender branches and drooping thong-like shoots which are destitute of leaves. The rather small pink or rosy flowers are borne during the summer months in racemes at the sides of the twigs, and give the plant a distinct and attractive appearance, resembling some of the Brooms. Calyx teeth short, nearly equal. The standard petal roundish, contracted at the base into a very short claw; wings oblong sickle-shaped, free; keel incurved, blunt. Stamens 10, the upper one free. Pod linear, flatly compressed.

Culture and Propagation.—This singular plant proves to be hardy out of doors in ordinary winters in the neighbourhood of London. It likes warm and sheltered situations fully exposed to the sun, and will flourish in ordinary good and well-drained garden soil, or a mixture of sandy peat and loam. It produces seeds freely and may be increased by this means. The seeds may be sown in cold frames as soon as ripe or in spring; cuttings of the ripened shoots will also root in sandy soil under the protection of a handlight.

CLIANTHUS (GLORY PEA; PARROT BEAK).—A genus of smooth or hairy climbing herbs or undershrubs with many-foliolate leaves, herbaceous stipules, and flowers in short, drooping, axillary racemes. Calyx teeth almost equal, the 2 upper ones broader at the base. Standard petal pointed, reflexed, longer than the falcate lance-shaped wings; keel straight or incurved, acute. Stamens 10, upper one free. Pod swollen, oblong, pointed, incurved.

C. Dampieri (Glory Pea).—A beautiful Australian species about 2 ft. high, with neatly winged, silver-grey, hairy leaves, and drooping clusters of large red flowers 5 or 6 on a stalk, with a blackish or dark purple blotch at the base of the standard petal. The variety *marginatus* has white flowers bordered with red, and a black blotch at the base of the standard.

Culture and Propagation.—This plant unfortunately is not quite hardy even in the mildest parts of the British Islands and should be slightly protected

in winter. Rich loamy soil and hot sunny positions suit it best. It may be raised from seeds sown under glass in gentle bottom heat, or may be increased from cuttings of the young shoots put in sandy soil under glass during the spring and early summer months.

C. puniceus (Parrot's Bill).—A brilliant New Zealand silky-haired species 6–10 ft. high. Leaflets alternate, oblong, leathery, retuse. Flowers in summer, scarlet, freely produced, with a large, boat-shaped, long-beaked keel. *Magnificus* is a strong-growing variety much harder than the type. A writer in the 'Gardeners' Chronicle' some years ago referred to a plant he grew on a south wall. It was 14 ft. high and had upwards of a thousand flowers all fully expanded at one time. The plant was killed down within 3–4 ft. of the ground in winter, and although two seedlings from it flowered and seeded in the open air in summer, they were both killed the succeeding winter. On the south-west coast of Scotland this variety seems to be hardy in ordinary winters.

Culture &c. The treatment of this species is the same as for *C. Dampieri*. Both species are very remarkable and beautiful when well grown, but it often happens that with the greatest care and the best cultural skill the plants fail to give an adequate return for the trouble bestowed upon them.

COLUTEA (BLADDER SENNA).—A genus containing 7 or 8 species of smooth or somewhat silky-downy shrubs, with oddly pinnate leaves, small stipules and flowers in axillary racemes. Calyx teeth nearly equal. Standard petal roundish; wings sickle-shaped oblong, short-clawed; keel broad, much incurved, blunt, with long united claws. Stamens 10, upper one free. Pod stalk papery, inflated, or bladder-like, and forming the main character of the genus.

Culture and Propagation.—Coluteas grow readily in any ordinary soil and in any situation, and may be increased from seeds sown as soon as ripe or in spring in warm sheltered spots out of doors; or cuttings of the more or less ripened shoots inserted in sandy soil in autumn will root freely under a handlight, and may be transplanted during mild weather the following spring.

C. arborescens.—A native of Central and S. Europe 6–10 ft. high. Leaflets

elliptic, depressed at the tips. Flowers from June to August, yellow, about 6 on a stalk. This species is said to grow on the Vesuvian crater. The variety *pygmaea* (or *crispa*) is a dwarf form with curled leaves.

Culture &c. as above.

C. cruenta (*C. orientalis*; *C. sanguinea*).—A native of S.E. Europe, 4-6 ft. high. Leaflets 7-9, glaucous. Flowers in summer, reddish-yellow, 3-5 on a stalk. *C. media* is very similar but has orange-yellow flowers.

Culture &c. as above.

C. halepica.—A native of the Levant 3-6 ft. high. Leaves glaucous, with small, numerous leaflets. Flowers in summer, yellow, larger than those of the other species. This plant is also known as *C. istria*.

Culture &c. as above.

HALIMODENDRON (SALT TREE).

A genus with only one species described herewith:—

H. argenteum (*Robinia Halodendron*).—A pretty shrub 4-6 ft. high, native of Asiatic Russia, with abruptly pinnate, silky, whitish leaves, having 2 pairs of leaflets, the main leaf stalk ending in a spine. Flowers from May to July, purplish, rather large, umbelled, axillary, or clustered on the old knots. Calyx gibbous behind, with short teeth. Standard roundish, folded at the edges; wings falcate-oblong, free; keel incurved, obtuse. Stamens 10, upper one free. Pod ovoid or oblong, much inflated, thickish, leathery.

Culture and Propagation.—The Salt Tree thrives in sandy soil and may be increased by seeds, cuttings, or layers. It is often grafted upon the common Laburnum and the Caragana and grown as a standard tree simply because seedling plants on their own roots often perish if placed in positions where the young stems are not much protected from keen cold winds. Once the stems have become well-ripened and woody, there is not so much danger of the plants dying. Under favourable conditions it is a handsome plant, the drooping clusters of purplish flowers being in strong contrast to the silvery white or grey of the foliage.

CARAGANA (SIBERIAN PEA TREE).

A genus with 15 species of ornamental trees or shrubs with abruptly pinnate

leaves, awl-shaped, spiny, or minute stipules, and axillary, solitary or crowded flowers, always on slender stalks. Calyx somewhat gibbous, teeth nearly equal. Standard petal ovate or roundish, folded at the sides, with a narrow claw; wings oblique, oblong, free; keel rather straight, obtuse. Stamens 10, upper one free. Pod sessile, linear, round or swollen.

Culture and Propagation.—Caraganas thrive in sandy soil, and are suitable for shrubberies. They may be raised from seeds, or increased by cuttings of the roots, and by layers. They are frequently grafted on *C. arborescens*, which is raised from seed sown as soon as ripe or in early spring.

Although not of the highest merit from a decorative point of view, the Caraganas nevertheless may be given a place in large gardens on account of their rather graceful habit, their perfect hardiness, and the fact that most of them will flourish in almost any poor soil.

C. arborescens.—A Siberian tree 15-20 ft. high. Leaflets 4-6 pairs, oval oblong, hairy; stipules spiny. Flowers in April and May, pale or bright yellow, in clusters, each flower having a slender stalk about 1 in. long. There are several varieties, the best being *nana*, which is a dwarf compact shrub with gnarled and knotted branches, the leaves and flowers, however, being similar to those of the type; *pendula*, as the name indicates, is a weeping variety and is usually grafted on tall stocks of the typical *C. arborescens* so that the branches may hang down more or less vertically; *Redowski* is remarkable for its long flexuous usually unbranched stems and its free-flowering character.

Culture &c. as above.

C. aurantiaca.—A comparatively recent introduction from Central Asia. It grows 3-4 ft. high and is closely related to *C. pygmaea*, but may be distinguished from that species by its larger and more distinctly lobed calyx and more pointed linear leaflets, of which latter there are 2 pairs issuing from the axil of a triple spine. The deep orange-yellow flowers hang down from the branches in great profusion in May and June and have a very ornamental appearance.

Culture &c. as above. Like most of the other species seeds are produced freely but the plants are usually grafted.

C. Chamlagu.—An ornamental shrub readily recognised by its deep glossy green leaves which are composed of 2 pairs of smooth obovate leaflets $\frac{1}{2}$ - $1\frac{1}{2}$ in. long, the outer pair being the larger. The rather large yellow flowers appear in early summer, one to each stalk, and as they begin to fade assume a reddish tint.

Culture &c. as above. This species is rarely or never seen on its own roots. It is usually grafted on standard stocks of *C. arborescens* about 4-5 ft. high, and assumes a drooping bushy habit that is very graceful.

C. frutescens.—A Siberian shrub 2-8 ft. high. Leaflets 2 pairs, obovate wedge-shaped, leaf stalk tipped with a short spine. Flowers in April, yellow, on twisted stalks. The variety *angustifolia* may be recognised by its narrow wedge-shaped leaflets ending in a point.

Culture &c. as above.

C. jubata (*Robinia jubata*).—A native of Siberia 1-2 ft. high. Leaflets 4-5 pairs, oblong lance-shaped, fringed with woolly hairs. Flowers in April, white or tinged with red, on very short stalks.

Culture and Propagation.—This remarkable species is readily recognised by its woolly bark and bristly stipules. It is not so amenable to cultivation as the other species, and is best grown near a south wall in dry sandy soil. It may be raised from seeds sown in cold frames when ripe, but the young plants should be well hardened off and be of a good sturdy growth before they are transferred to the open ground. It may also be grafted like the other species.

C. microphylla (*C. Altagana*).—Native of Dahuria 2-8 ft. high, with long slender graceful branches. Leaflets in 6-8 pairs, smooth, obovate roundish, retuse, about $\frac{1}{4}$ in. long. Flowers from April to July, yellow, solitary.

Culture &c. as above.

C. pygmæa.—A graceful shrub about 3 ft. high, with long slender branches and a rather straggling or drooping habit. It exists in a wild state from the Caucasus to the Himalayas. The leaves are very closely arranged on the stems, and each one is composed of 2 pairs of small narrow leaflets about $\frac{1}{4}$ in. long. The drooping bright yellow flowers appear in May and

June, and seeds are in due course also freely produced.

Culture &c. as above.

C. spinosa.—Native of Siberia 4-6 ft. high. Leaflets 2-4 pairs, wedge-shaped linear, smooth; stipules spiny; old leaf stalks strong, persistent, spiny. Flowers in April and May, yellow, nearly sessile.

Culture &c. as above.

CALOPHACA.—A genus with 6 or 7 species of woolly or smooth perennial herbs or undershrubs, with characters similar to Caragana.

C. volgarica.—A Siberian deciduous shrub 2-3 ft. high, with 6-7 pairs of roundish leaflets, velvety beneath, racemes of yellow flowers in May and June, followed by beautiful reddish pods.

Culture and Propagation.—This species is the one usually grown and is useful for the shrubbery. The seeds are produced in abundance in fine seasons, and plants may be raised from them. It is often grafted on tall stems of the Laburnum and looks very effective in bloom.

ASTRAGALUS (MILK VETCH).—A genus containing more than 600 species of dense, very much branched, often spiny, annual or perennial herbs or undershrubs, most of them useless from a garden point of view. Calyx tubular, 5-toothed. Petals often long-clawed; standard erect, ovate oblong, or fiddle-shaped; stamens 10, upper one free. Pod sessile or stalked.

Culture and Propagation.—The Milk Vetches grow well in any light dry soil, and may be increased by dividing the roots, by seeds, or in the case of shrubby sorts also by cuttings in a cold frame. The seeds are usually a long time sprouting and are best sown as soon as ripe in pots or pans under glass. The plants may be used for the decoration of the rock garden in the somewhat rougher parts, or massed in rougher parts of the garden in dry soils. Besides the species referred to below there are many others to be met with in botanic gardens.

A. adsurgens.—A somewhat rare and handsome smoothish Siberian perennial, with 11-12 pairs of ovate lanceolate acute leaflets. Flowers in June, bluish-purple, densely packed on oblong spikes.

Culture &c. as above.

A. aduncus.—A Caucasian perennial 6-9 in. high. Leaflets in numerous pairs, roundish-ovate, smooth, downy. Flowers in summer, rose-purple, in oblong spikes.

Culture &c. as above.

A. alopecuroides.—A fine erect Siberian perennial 2-5 ft. high. Leaflets numerous, ovate-lance-shaped, downy; stipules similar, pointed. Flowers in June, yellow, densely crowded.

Culture &c. as above.

A. arenarius.—A whitish-hairy Danish perennial about 6 in. high. Leaflets linear, blunt; stipules united opposite the leaves. Flowers in June, blue.

Culture &c. as above.

A. austriacus.—A spreading procumbent European perennial. Leaflets smooth, linear, truncately emarginate. Flowers in May, purple, with a blue standard.

Culture &c. as above.

A. canadensis.—A rather hairy Canadian perennial 2-3 ft. high, with 10-12 pairs of elliptic-oblong, bluntish leaflets. Flowers in July, yellow.

Culture &c. as above.

A. dahuricus.—An erect, hairy, Siberian perennial 1-2 ft. high, with 7-9 pairs of oblong, mucronate leaflets. Flowers in July, purple, in dense racemes.

Culture &c. as above.

A. dasyclottis.—A charming spreading Siberian alpine perennial 3-4 in. high. Leaflets elliptic-oblong, rather emarginate; stipules united, opposite the leaves. Flowers in June, purple, blue, and white, mixed.

Culture &c. as above.

A. falcatus (*A. virescens*).—An erect, hairy perennial 1-2 ft. high, native of wet, grassy places in Siberia. Leaflets 16-20 pairs, elliptic-oblong acute. Flowers in June, greenish-yellow, in spikes.

Culture &c. as above.

A. galegiformis.—A striking Siberian perennial 3-5 ft. high, with 12-13 pairs of elliptic-oblong leaflets. Flowers in June, pale yellow, in drooping racemes.

Culture &c. as above.

A. Glyciphyllus.—A British perennial with stout, prostrate, zigzag stems 2-3 ft. long. Leaflets 5-7 pairs, oval, blunt, smooth; stipules ovate lance-shaped, entire. Flowers in June, sulphur-yellow.

Culture &c. as above.

A. hypoglottis (*A. danicus*).—A hairy prostrate British perennial, 3 in. or more high. Leaves 2-4 in. long, with numerous small, oblong linear, blunt, deep green leaflets. Flowers in summer, bluish-purple, in round heads. The variety *albus* differs only in having white flowers.

Culture &c. as above.

A. leucophyllus.—A N. American perennial 2-3 ft. high. Leaflets in numerous pairs, broadly linear, covered with soft silky down. Flowers in summer, pale yellow, in dense racemes.

Culture &c. as above.

A. maximus.—A handsome erect Armenian perennial 2-3 ft. high. Leaflets ovate lance-shaped, downy; stipules oblong lance-shaped. Flowers in June, yellow, in cylindrical sessile spikes.

Culture &c. as above.

A. monspessulanus.—A beautiful vigorous evergreen trailing perennial, stems 18 in. long, with 10-20 pairs of ovate acute, hoary leaflets. Flowers in June, pale rosy-lilac with bars of white on the standard petals, in racemes 2-5 in. long.

Culture &c. as above.

A. onobrychioides.—A handsome Persian perennial 9-12 in. high, with 8-10 pairs of elliptic leaflets, and united stipules opposite the leaves. Flowers in July, bright purple.

Culture &c. as above.

A. Onobrychis.—An elegant more or less trailing perennial, native of Central and S. Europe, with stems about 18 in. long, and 7-16 pairs of oblong leaflets. Flowers in June, purple. There are several white-flowering varieties, of which *alpinus* is the one best known.

Culture &c. as above.

A. pannosus.—A pretty Siberian perennial 6-9 in. high, with 4-9 pairs of ovate lance-shaped leaflets, and compact rounded heads of rosy flowers in July.

Culture &c. as above.

A. ponticus.—A rather hairy-stemmed vigorous perennial 2-3 ft. high, native of Tauria and Bessarabia, with oblong, smoothish leaflets, lance-shaped stipules, and yellow heads of flowers in July.

Culture &c. as above.

A. sulcatus.—A smooth Siberian perennial with furrowed stems 2-3 ft. high, and linear lance-shaped leaflets.

Flowers in July, pale violet, with a white keel tipped with brown.

Culture &c. as above.

A. Tragacantha (*Great Goat Thorn*).

An evergreen spiny shrub 1½–3 ft. high, native of the Levant. Leaves hoary, with 7–9 pairs of linear, hairy leaflets; stalks becoming spiny when old. Flowers in June, pale violet, 2–5 together in the axils of the leaves. It was at one time erroneously thought that Gum Tragacanth was obtained from this plant.

Culture &c. as above.

A. vaginatus.—A handsome Siberian perennial 1 ft. high, with 7 or 8 pairs of elongated oblong leaflets covered with short silvery hairs. Flowers in summer, rosy-purple, with white-tipped wings, in dense spikes. Calyx rather inflated, covered with soft white and black hairs.

Culture &c. as above.

A. vesicarius.—A perennial hoary trailer 6–12 in. high, native of France. Leaflets 5–7 pairs, elliptic. Flowers in July, standard petal purple, wings yellow, keel white tipped with yellow. Calyx covered with black down and long white hairs.

Culture &c. as above.

A. vimineus.—A very handsome Siberian perennial 6–12 in. high, with 4–6 pairs of lance-shaped acute leaflets covered with adpressed hairs. Flowers in June, standard petal purple-rose, longer than the pure white wings. Calyx covered with black hairs.

Culture &c. as above.

A. vulpinus.—A pretty smooth-stemmed Caucasian perennial 2–3 ft. high, with obovate blunt, rather velvety leaflets. Flowers in June, pale yellow, in almost globose spikes.

Culture &c. as above.

OXYTROPIS.—A genus with 100 species of much-branched herbs or undershrubs, with the habit and floral characters of *Astragalus*, from which it differs chiefly in the flowers having a mucronate or pointed keel. Leaves oddly pinnate. Stipules adnate to the leaf stalk or free. Flowers in axillary spikes or racemes.

Culture and Propagation.—These plants prefer a dry, sandy, loamy soil, but are not particular so long as they are not in stagnant, moist spots. They are in-

creased by seeds sown in the open border or by division of the plants in spring, and may be utilised for the rougher parts of the rock garden.

O. campestris.—A pretty Scotch alpine 3–6 in. high, with many pairs of lance-shaped acute, hoary leaflets. Flowers in July, creamy-white with purple-tinted wings and keel, scapes hairy, crowded.

Culture &c. as above.

O. fetida.—A clammy, smelling plant 4–6 in. high, native of S. France, with many pairs of smooth lance-shaped linear leaflets, and creamy-white flowers in July.

Culture &c. as above.

O. Halleri.—An elegant Scotch silky-haired species 6 in. high, with ovate acute leaflets and rich bluish-purple, or rarely white, flowers in July, in round dense heads.

Culture &c. as above.

O. Lamberti.—A rare and beautiful stemless rock plant 6–12 in. high, native of N. America, with silky and hairy lance-shaped acute leaflets. Flowers in August, rosy-carmine.

Culture &c. as above.

O. montana.—A hairy European species 6 in. high, with elliptic lance-shaped leaflets and short racemes of bluish-purple flowers in summer.

Culture &c. as above.

O. pilosa (*Astragalus pilosus*).—A pretty softly hairy Siberian species about 6 in. high, with lance-shaped acute leaflets and pale yellow flowers in July.

Culture &c. as above.

O. pyrenaica.—A handsome Pyrenean species 4–6 in. high, with lance-shaped or oblong pointed leaflets covered with long silky hairs. Flowers in summer, sky-blue, erect, 9–15 on a short crowded raceme. Calyx very hairy, with short lance-like teeth.

Culture &c. as above.

O. uralensis.—A pretty Scotch and European perennial with 10–15 pairs of ovate acute leaflets, and dense round heads of bright purple flowers in summer. Very similar to *O. campestris*.

Culture &c. as above.

CORONILLA.—This genus contains about 20 species of smooth rarely silky herbs or shrubs, with oddly pinnate leaves, and flowers on long-stalked

axillary umbels. Calyx teeth nearly equal, 2 upper ones united. Petals rather long-clawed; standard roundish; wings obliquely obovate or oblong; keel incurved, beaked. Stamens 10, upper one free. Pod round, 4-angled or slightly compressed, straight or curved.

Culture and Propagation.—The hardy Coronillas may be increased by cuttings inserted in sandy soil in a cold frame or greenhouse in spring. The roots may also be divided. Seeds if sown as soon as ripe will give a fair percentage of good seedlings. They thrive in a mixture of good loam and peat, and are excellent for the rougher parts of the rockery, the margins of shrubberies, or the front of mixed borders. *C. glauca*, a lovely greenhouse plant with glaucous foliage and yellow flowers, may be grown outside in the very mildest parts of the country.

C. Emerus (Scorpion Senna).—An elegant S. European shrub 3-6 ft. high, with 5-7 obovate leaflets, and yellow flowers in April, 3-5 on a stalk. In mild winters the leaves may remain on the plant.

Culture &c. as above. Increased by seeds or cuttings.

C. iberica.—A pretty prostrate rock plant, with more or less ascending stems 6-8 in. high, and 9-11 obovate, ciliate leaflets; stipules distinct, roundish, toothed. Flowers in July, yellow, large, 7-8 in an umbel. This species is also known as *C. cappadocica*, and is a native of Asia Minor.

Culture &c. as above. Increased by seeds or division.

C. juncea.—A pretty rush-like shrub 2-3 ft. high, native of S. Europe. The round whip-like branches are sparingly furnished with leaves which are composed of 3-7 bluntly linear lance-shaped leaflets of a rather fleshy texture. The bright yellow flowers appear in June 5-7 in a cluster at the sides of the branches.

Culture &c. as above. This species is fairly hardy in the neighbourhood of London in ordinary winters. It should be grown in a sunny sheltered situation.

C. varia.—A pretty European species with trailing stems often 4-5 ft. long, and 11-13 oblong elliptic mucronate leaflets. Flowers from June to November, pink and white, or rarely white, 16-20 in an umbel.

Culture &c. as above. This species

likes a somewhat chalky soil, and may be used for trailing over rocks in the rock garden. Seeds may be sown in the open air in April and May, or as soon as ripe in cold frames. In the latter case the seedlings may be transplanted the following spring.

HIPPOCREPIS (HORSESHOE VETCH).—A genus with about 12 species of usually smooth spreading herbs or undershrubs with oddly pinnate leaves, and flowers in axillary stalked umbels. Petals long-clawed; standard roundish; wings falcate, obovate or oblong; keel incurved, beaked. Stamens 10, upper one free. Pod compressed, or rarely round, often curved, breaking up into 3-6 horse-shoe-like joints.

H. comosa.—A British, European, and N. African plant with trailing stems, 6 in. long, and 7-15 obovate obtuse leaflets. Flowers in spring and summer, yellow, 5-8 in an umbel.

Culture and Propagation.—This plant grows easily in ordinary soil and may be increased by seeds sown in spring in the open air, or in autumn as soon as ripe; or division of the roots may also be practised in autumn and spring. The plants are suitable for the rockery or border.

HEDYSARUM.—A genus with 50 species of smooth, hoary or silky-haired perennial herbs or undershrubs, with oddly pinnate leaves and flowers in axillary racemes. Standard obovate or obovate, narrowed at the base, scarcely clawed; wings oblong, sometimes very short; keel obliquely truncate. Stamens 10, upper one free. Pod flattened with rounded or quadrate joints.

H. coronarium (French Honey-suckle).—A pretty S. European perennial 3-4 ft. high, with 3-5 pairs of elliptic or roundish leaflets, downy beneath. Flowers in summer, deep red, in crowded spikes or racemes. There is a variety with white flowers.

Culture and Propagation.—This species grows freely in ordinary garden soil, and reproduces itself from self-sown seed, in favourable sunny spots in deep soil. In cold parts of the kingdom it may be advisable to give a little protection in winter with dry leaves &c. during severe weather. There are several other species grown in botanical collections.

H. Mackenzi.—A rather handsome N. American perennial 2-3 ft. high, the pinnate leaves of which are made up of 5-7 pairs of oval, blunt, or retuse leaflets. The pretty rose-purple flowers appear in early summer in long loose racemes.

Culture &c. as above for *H. coronarium*. Seeds are freely ripened.

H. microcalyx.—A pretty half shrubby perennial 2-5 ft. high, native of the N.W. Himalayas. The pinnate leaves are 6-12 in. long, and composed of 17-21 oblong blunt leaflets each $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long. The bright purple flowers appear in June in racemes 6-12 in. long.

Culture &c. as for *H. multijugum*.

H. multijugum.—A shrub 2-5 ft. high native of S. Mongolia. The plant is covered with soft silky hairs, and the leaves are composed of 20-30 bluntly obovate or oblong leaflets, silky beneath. The pale pinky-red flowers appear in early summer and are borne in racemes in the axils of the leaves.

Culture and Propagation.—This species produces seeds freely in the open air, and new plants may be obtained by sowing them as soon as ripe or in spring in cold frames, afterwards transplanting the seedlings when large enough. Cuttings of the young flowerless shoots may also be inserted in sandy soil in spring or early summer under a glass.

ONOBRYCHIS (*Sainfoin*).—A genus with over 70 species of unarmed herbs or undershrubs, rarely very spiny shrubs. Leaves oddly pinnate, stipules scarious. Flowers in stalked spikes or racemes. Standard petal obovate or obcordate, narrow at the base, scarcely clawed; wings short, or very short; keel obliquely truncate at the apex, blunt, equal to or longer than the standard. Pod flattened half-round or roundish-circinate, unjointed.

O. sativa (*Common Sainfoin*).—A British and European species 2-3 ft. high, with elliptic-oblong, mucronate leaflets, and bright rosy-red flowers with darker veins in ovoid compact racemes in summer. The variety *montana* is a more desirable plant 6-12 in. high, from the Alps. It is a pretty decumbent rock plant, with cuneate lance-shaped, mucronulate leaflets, and purplish-rose flowers.

O. Laconica is a beautiful species differing from *O. sativa* in its larger bright

pink flowers, more glaucous foliage, and a dwarfier and more compact habit.

Culture and Propagation.—Very few species are cultivated. They like deep sandy, loamy soils, and are easily increased from seeds sown in spring or autumn in the open border where the plants are to bloom. Open sunny situations suit them best.

LESPEDEZA.—A genus containing about 25-30 species of shrubs or undershrubs often covered with soft silky hairs. Leaves pinnately 3-foliolate. Stipules free, often minute. Flowers purplish, rose, or white, borne in axillary clusters or racemes, or in panicles at the ends of the branches. Calyx lobes or teeth nearly equal, or the 2 upper ones slightly united. Standard petal obovate or oblong, with a narrow claw; wings falcate-oblong, free or slightly adhering to the incurved, blunt or beaked keel. Upper stamen free, or rarely uniting with the others. Pod ovate or roundish, flatly compressed.

L. bicolor.—A handsome shrub 4-8 ft. high, native of China and Japan. It has dark brown minutely warty stems distinctly ribbed when young and covered with greyish downy hairs. The leaves are composed of 3 more or less oval-elliptic leaflets $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long, and much broader than those of *L. Sieboldi*. The large branching racemes of blossoms are much less dense than those of *L. Sieboldi*, and the individual flowers also are somewhat smaller and not so highly coloured with rose-purple.

Culture and Propagation.—This species flourishes in ordinary good and well-drained garden soil, and is hardy in ordinary winters in the neighbourhood of London. It should be grown in warm and sheltered spots in order to secure the best results. Seeds may be sown in cold frames when ripe, and cuttings of the more or less ripened shoots may also be inserted in sandy soil under a handlight during the summer and autumn months.

L. Sieboldi (*Desmodium penduliflorum*).—A handsome hardy shrub 5-6 ft. high, native of N. China and Japan, with drooping branches and Laburnum-like leaves composed of 3 oblong lance-shaped leaflets, the terminal one of which has a much longer stalk than the others, but they are all covered with white hairs on the under surface. The pretty rose or lilac-purple pea-like flowers are produced

in great profusion during the summer months in long slender drooping racemes 6-8 in. long, and give the plant a characteristic appearance. There is also a white-flowered form which is very handsome.

Culture and Propagation.—Although usually described as a shrub, *L. Sieboldi* is in reality an herbaceous perennial, as its stems are cut down to the ground every winter. New ones appear every spring, and the number thus increases and adds to the effect when in bloom. This species may be easily increased by division of the roots in early autumn and also in spring; and also by seeds in the same way as for *L. bicolor*.

Other species of recent introduction are *L. Delavayi* from Yunnan. It grows 3-6 ft. high and has a bushy habit. The 3 blunt elliptic leaflets are green above and silvery beneath, and the deep purple or violet flowers are borne in large panicles at the ends of the branches. *L. macrocarpa* from N. China is a shrub with racemes of small purple flowers, and *L. trigonoclada* is a remarkable herbaceous perennial with triangular stems, smooth leathery leaves, and panicles of pale yellow or whitish flowers. It is a native of China.

VICIA.—A genus with over 100 species of annual or perennial herbs, with abruptly pinnate leaves, the stalks of which often end in a simple or branched tendrill. Flowers axillary or racemose. Standard petal obovate or oblong, emarginate; wings obliquely oblong, adhering to the falcate oblong or broad keel at the middle. Upper stamen free, or more or less united with the other nine. Pod flattened.

Culture and Propagation.—When grown in large clusters in borders some of the *Vicias* are very effective when in bloom, but afterwards they present a somewhat straggling and disorderly appearance. The weak stems require branches to hold them up. They will grow in any garden soil in open situations and may be increased by seeds sown either in spring or autumn in the open border; or in the case of perennials, by dividing the rootstock also in early autumn or spring.

V. argentea.—A Pyrenean perennial about 1 ft. high, with 4-angled stems, silvery leaves without tendrills, and oblong-linear, mucronate leaflets. Flow-

ers in June, pink, many on a stalk, with a black-spotted keel.

Culture &c. as above.

V. Cracca (*Cow Vetch*; *Tufted Vetch*).—A rather pretty British perennial 2-6 ft. long. Leaves 1-4 in. long, with many linear-oblong, acute or mucronate leaflets. Flowers from June to August, bright blue, in dense racemes.

Culture &c. as above.

V. gigantea.—An ornamental species 3-5 ft. high. Leaves with about 13 pairs of oblong, mucronate leaflets. Flowers in June and July.

Culture &c. as above.

V. onobrychioides.—A pretty South European annual 2 ft. high. Leaflets numerous, linear, obtuse, or mucronulate. Flowers in June, purple, many on a long stalk.

Culture &c. as above.

V. tenuifolia.—A climbing perennial 1-2 ft. high, native of Germany and Tauria. Leaflets linear, smoothish, mucronate. Flowers in June, violet, in clustered, long-stalked racemes.

Culture &c. as above.

LATHYRUS (SWEET and EVERLASTING PEA).—A genus containing about 100 well-marked species of dwarf or climbing annual or perennial herbs. Leaves pinnate, the stalk ending in a tendrill. Stipules leafy, more or less arrow-shaped, rarely entire at the base. Flowers on axillary, elongated stalks, solitary or racemed. Standard petal broadly ovate or roundish, emarginate; wings falcate-obovate or oblong, slightly adhering at the middle of the shorter incurved obtuse keel, or nearly free; upper stamen free or more or less united with the others. Pod flattened or nearly round. For cutting purposes both Sweet and Everlasting Peas are extremely valuable. The blossoms last a long time in water, and by constantly cutting the sprays fresh flowers are developed.

Culture and Propagation.—Most of the *Lathyrus* are pretty garden plants. They thrive in rich loamy soil, but many of them are not particular so long as the ground is fairly good. Grown as masses over rough slender branches in the open border, against walls, over trellises or arbours, both the annual and perennial kinds look very effective. The perennial sorts may be divided at the root in spring;

or they may, like the annuals, be sown in the open ground at that period. A few more cultural details will be found under the 'Sweet Pea' (*L. odoratus*).

L. californicus.—This is a native of N. California—closely related to if not actually a variety of the British Beach Pea (*L. maritimus*). It has 4–5 pairs of ovate-oblong, smooth, glaucous, sharply pointed leaflets, and semi-sagittate stipules. Flowers from July to September, many on a stalk, large, purple, with deeper veins.

Culture &c. as above.

L. Davidi.—This perennial species is a native of N. China and Japan, and has pinnate leaves ending in a tendril. There are 3–4 elliptic-acute leaflets $1\frac{1}{2}$ –2 in. long, and the yellowish-white flowers appear in summer on long-stalked racemes.

Culture &c. as above.

L. grandiflorus.—A beautiful large-flowered species native of S. Europe, with 4-angled winged stems. Leaves with one pair of ovate, blunt, wavy leaflets, and small semi-sagittate stipules. Flowers from June to August, rosy-red.

Culture &c. as above. This species should not be planted too close to other plants, as its roots travel to a great distance and send up shoots from all parts, thus sometimes becoming a nuisance.

L. heterophyllus.—An 'Everlasting' Pea with erect rigid winged stems, native of Europe, one or two pairs of lance-shaped mucronulate leaflets, and winged leaf stalks. Flowers from July to September, 6–8 on a stalk, large flesh-coloured, with a whitish keel.

Culture &c. as above.

L. lætiflorus.—A Californian perennial 6–8 ft. high, with light green leaves cut into about a dozen small leaflets. The flowers appear in summer and are white or faintly flesh-coloured, the standard being veined and washed with bright pink behind.

Culture &c. as above. This requires a little protection in Scotland during winter. A warm sheltered spot suits it best.

L. latifolius (*L. sylvestris platyphyllus*). *Everlasting Pea.*—This beautiful and well-known climber is to be found in almost every garden, great and small. It is a native of Europe, and has winged stems, and leaves with one pair of elliptic

mucronate leaflets. Stipules broad ovate. Flowers in summer, large, rosy, many on a stalk. The white variety *albus* is very beautiful.

Culture &c. as above.

L. magellanicus (*L. armitageanus*).—*Lord Anson's Pea.*—A strong-growing 'Everlasting' Pea, native of the Straits of Magellan. Leaves with one pair of ovate-oblong leaflets heart-shaped-sagittate stipules, broader than the leaves. Flowers from June to September, bluish-purple, many on a long stalk.

Culture &c. as above.

L. odoratus (*Sweet Pea*).—The wild Sweet Pea is a native of South Europe, with ovate sharply pointed leaflets, semi-sagittate, lanceolate leaflets, and winged stems. Flowers in summer, variously coloured, several on a stem.

Of late years the Sweet Pea has leaped into popular favour to such an extent that it has almost excluded most of the other kinds from the garden. There are about 150 varieties now sold, and they are nearly all charming in colour and free in flowering.

Culture and Propagation.—To obtain the best results from Sweet Peas they should be grown in well-manured and deeply dug loamy soil. The seeds may be sown out of doors in April in patches or rows according to the purpose for which they are required. They should be protected from the birds by wire netting or branches. When well above the ground slender twigs or stakes may be put to them for climbing. They will reach a height of 4–7 feet or more during the summer, and flower profusely. To prolong the period of flowers and a greater supply of them, the faded blooms should be picked off so as to prevent the development of seed-pods except on special varieties from which it is desired to save seeds. During hot dry summers a mulching of rotted manure and plenty of water will be beneficial.

Where cold frames or greenhouses exist, it is much better to sow the seeds about 5 or 6 in a 5 in. pot in February, having previously steeped them in cold or warm water for a few hours. When an inch or two high, plenty of light and air should be given—always excluding frost. By the end of April or May according to locality and mildness or otherwise of the season, they will be sturdy for planting

out, after which they may be staked and treated as above. In mild seasons, however, they may be planted out about the second or third week in March with safety if they have not been grown in too high a temperature previously.

The variety of uses to which Sweet Peas may be put are many, and one of their great charms is to make an otherwise dingy-looking garden bright and gay, and give an abundance of blossom, which if picked when just opening and on long stalks will last a week or more in vases of fresh water.

A few of the best varieties grown are mentioned below, and an attempt has been made to group them according to the prevailing colour.

White Sweet Peas.—Blanche Burpee, Cupid, Emily Henderson, Mrs. Sankey, Queen of England, Saidie Burpee, Sensation.

White, Blush, shaded or striped Pink, Rose, Purple, Lavender &c.—Aurora, Capt. Clark, Daybreak, Delight, Dolly Varden, Duchess of Sutherland, Earliest of All, Eliza Eckford, Empress of India, Gaiety, Isa Eckford, Juanita, Lemon Queen, Princess of Wales, Ramona, Senator.

Pink, Cerise, in various shades.—Adonis, Alice Eckford, Apple Blossom, California, Countess of Aberdeen, Countess of Shrewsbury, Cupid, Duke of York, Emily Lynch, Hon. F. Bouverie, Katherine Tracey, Lady Mary Currie, Lord Penzance, Lottie Hutchins, Lovely, Modesty, Mrs. Gladstone, Ovid, Peach Blossom, Pink Friar, Prima Donna, Princess Beatrice, Red Riding Hood, Royal Robe, Royal Rose, Violet Queen.

Purple in various shades.—Black Knight, Captain of the Blues, Carmen Sylva, Countess of Cadogan, Dorothy Tennant, Duke of Clarence, Duke of Sutherland, Duke of Westminster, Emily Eckford, Fashion, Grand Blue, Imperial Blue, Indigo King, Madame Carnot, Maid of Honour, Monarch, Navy Blue, Othello, Purple Prince, Shahzada.

Lavender, Heliotrope, Lilac, various shades.—Burpee's Bush Sweet Pea (18–24 in. high), Colonist, Countess of Radnor, Creole, Duchess of York, Golden Gate, Grey Friar, Lady Grisel Hamilton, Lady Nina Balfour, Lottie Eckford, New Countess, Princess May, Wawona.

Yellow, Primrose, Orange, Salmon, various shades.—Chancellor, Coquette, Countess of Powis, Golden Gleam, Gor-

geous, Lady Beaconsfield, Meteor, Mrs. Eckford, Oriental, Primrose, Queen Victoria, Stella Morse, Triumph.

Rose, Crimson, Scarlet, Red.—American Belle, Blanche Ferry, Brilliant, Bronze King, Cardinal, Duchess of Edinburgh, Firefly, Her Majesty, Ignea, Invincible Carmine, Little Dorrit, Mars, Mikado, Miss Hunt, Mrs. Dugdale, Novelty, Oddity, Painted Lady, Prince of Wales, Prince Edward of York, Queen of the Isles, Rising Sun, Salopia, Scarlet Invincible, Splendour, Stanley, The Belle, The Queen, Vesuvius.

L. pubescens.—A charming Chilean perennial about 6 ft. high, with a somewhat shrubby habit, and oddly pinnate leaves more or less covered with down all over. The large and beautiful pale lilac-purple flowers appear in June in dense racemes, and seeds are produced in due course if the blooms are allowed to remain unpicked.

Culture &c. as above. In the colder and more northern parts of the country it is advisable in severe winters to give a little protection to the dormant roots with some dry leaves, bracken &c.

L. roseus.—A native of Spain, with ovate, roundish leaflets, very short tendrils, and small awl-shaped stipules. Flowers in summer, rosy, on thread-like stalks.

Culture &c. as above.

L. rotundifolius (L. Drummondii).—A pretty Everlasting Pea, native of Persia, Asia Minor &c., with ovate, roundish leaflets, semi-sagittate stipules, and winged branching stems. Flowers from May to July, bright rose-pink, an inch across, and in large clusters.

Culture &c. as above.

L. Sibthorpi.—A beautiful early-flowering Everlasting Pea, 2–3 ft. high. The flowers appear in May and June in rich masses and are of a beautiful rosy-purple colour, very useful for cutting.

Culture &c. as above.

L. splendens (Pride of California).—A beautiful Everlasting Pea, native of southern California. It has 4-angled stems about 12 ft. long, and slender pinnate grey-green leaves. From 6 to 12 very distinct carmine-red blossoms are borne on the racemes during the summer months in the open air, but somewhat earlier in a greenhouse.

Culture &c. as above. This species

requires very hot and dry situations, but likes plenty of water during growth. It is rather too tender for any except the mildest parts of the kingdom out of doors, but makes a charming and brilliant climber for cold greenhouses.

L. tingitanus (*Tangier Pea*).—A pretty Tangierian annual, with winged stems, ovate, blunt, sharply pointed leaflets, and ovate, semi-sagittate stipules. Flowers in summer, with a large purple standard, and bright red wings and keel.

Culture &c. as above.

L. tuberosus.—This native of Europe, Asia, and N. Africa is now naturalised in some parts of England, and is also grown in Holland for its edible, tuberous roots. The stems are 4-angled, and the leaves have one pair of oblong, elliptic leaflets, and narrow, acute, semi-sagittate stipules. Flowers in summer, large, rosy, 3-6 on a stalk, very free.

Culture &c. as above. As the roots of this species travel a good deal under ground, plants should be placed where they will not interfere with choicer subjects.

L. violaceus.—A rather pretty Californian perennial 6-8 ft. high, with pale green leaves composed of 10-12 leaflets, and racemes of violet-blue flowers produced in summer.

Culture &c. as above. Requires protection in northern parts in winter.

OROBUS (BITTER VETCH).—Bentham and Hooker consider this to be merely a botanical section of *Lathyrus*. For garden purposes, however, it is quite distinct, and is best kept separate from the Sweet and Everlasting Peas. It differs from *Lathyrus* chiefly in having no tendrils at the tip of the leaf-stalk, and in the plants as a rule being dwarf, tufted, and non-climbing in habit.

Culture and Propagation.—They thrive in any good garden soil, and are easily increased by dividing the root-stocks in spring, or by sowing seeds at the same period. They are suitable for rougher parts of the rockery, margins of shrubberies, borders &c.

O. atropurpureus.—An elegant Algerian perennial 1-1½ ft. high, with leaves composed of 2-3 pairs of sharp linear leaflets and small semi-sagittate stipules. The deep rose or violet-purple flowers appear in May and June in loose racemes.

Culture &c. as above. In cold northern parts this species requires protection in winter with dry leaves &c.

O. aurantius.—A Caucasian perennial 1½-2 ft. high, with 5-6 pairs of lance-shaped, bluntish leaflets, and deep yellow flowers in early summer.

Culture &c. as above.

O. cyaneus (*Platystylis cyaneus*).—A pretty Caucasian species 6-12 in. high. Leaves with 2-3 pairs of closely set, narrow, lance-shaped, acute leaflets. Flowers in spring, blue at first, changing to purple, large, handsome, few on a stalk.

Culture &c. as above.

O. filiformis (*O. canescens*).—A native of S. Europe, with 4-angled stems, and leaves with 2-3 pairs of linear, bluntish, downy or dotted leaflets. Flowers in May, white, tinged with blue, many on a stalk.

Culture &c. as above.

O. flaccidus.—A native of Croatia, 6 ft. high. Leaves with 2-3 pairs of long, smooth, opposite, linear leaflets, dark green above, pale beneath; stipules large, semi-sagittate. Flowers in May, purple, with 2 prominent blunt teeth near the middle of the standard petal.

This is closely related to *O. vernus*, and is regarded as a botanical form of it.

Culture &c. as above.

O. hirsutus.—A native of Thrace, 1 ft. high. Leaflets ovate, acute, parallel-nerved. Flowers in May, red.

Culture &c. as above.

O. lathyroides (*Vicia oroboides*).—A pretty Siberian species, 1-1½ ft. high. Leaves composed of 2 leaflets 2 in. long, 1 in. broad, oval, lance-shaped acute; stipules semi-sagittate, toothed at the base. Flowers in early summer, blue, small, numerous.

Culture &c. as above.

O. luteus.—A handsome Siberian species 1-2 ft. high. Leaves with 3-5 pairs of elliptic lance-shaped, pointed leaflets, glaucous beneath. Flowers in June, yellow, many on a stalk.

Culture &c. as above.

O. niger.—A pretty European species 1½-3 ft. high, with flexuous stems, and glaucous green leaves composed of about 8 pairs of small oval-oblong leaflets. In June and July about 8-12 handsome

violet-red flowers are borne on the racemes which are freely produced.

Culture &c. as above. This graceful species is remarkable for the blackish tint of the foliage when drying off.

O. pannonicus.—A native of South Europe, 1 ft. high. Leaves with 2-3 pairs of linear, mucronate leaflets. Flowers in May, varying from white and cream tinged with rose to purple and white and yellow, many on a stalk. The variety *varius* has rose standards, and yellowish wings and keel, and angular stems.

Culture &c. as above.

O. variegatus.—A native of S. Europe, with flexuous stems 1 ft. high. Leaves with 2-3 pairs of ovate lance-shaped pointed leaflets. Flowers in early summer, beautifully variegated, the standard fine rose, veined and netted with purple-crimson, the wings being tipped with blue.

Culture &c. as above.

O. vernus.—A beautiful Central and S. European perennial, 1-1½ ft. high. Leaves with 2-3 pairs of shining, ovate pointed leaflets, and semi-sagittate stipules. Flowers in spring, purple and blue, with red veins, the keel tinged with green, freely produced on one-sided nodding stalks. There is a white-flowered variety (*albus*) and also a double-flowered form of the coloured type.

Culture &c. as above.

ERYTHRINA (CORAL TREE).—A genus with about 25 species of trees or shrubs, often thick and prickly. Leaves pinnately 3-foliolate; stipules small. Flowers usually bright scarlet, in terminal racemes. Standard petal larger and longer than wings or keel. Calyx spathe-like, truncate, 5-toothed. Stamens 10, upper one usually free. Pod stalked, linear, falcate, flattened or round.

E. Crista-galli.—This is a beautiful Brazilian shrub 6-8 ft. high, with ovate, rather glaucous leaves, leathery leaflets, and prickly, glandular stalks. Flowers in early summer, deep brilliant scarlet, in large trusses at the ends of the branches, often 12-20 in a raceme. There are several varieties, all useful for decorating the garden during the summer months if too tender to stand the winter.

Culture and Propagation.—This species will grow against a warm south wall for many years if the rootstock is

protected from frost by ashes, litter &c., and every spring it will send up its thick shoots. It should be grown in rich loamy soil, and during active growth should have plenty of water. In winter, however, it must be kept dry.

Another and very general method of cultivation is to treat the Coral Tree exactly in the same way as Dahlias. The thick rootstocks are lifted as soon as frost appears and are wintered in dry sheds or cellars free from frost, after the old stems have been cut down to within a few inches of the base. About February or March they are placed in a warm greenhouse or hotbed, slightly covered with soil and gently watered from time to time. This treatment induces the development of strong young stems, and as many as 40 or 50 will be produced on a good strong and healthy old rootstock. The plants may be potted up and grown on under glass till the end of May or June, until the weather is favourable enough for outdoor planting. Grown in large bold groups on the grass, as is done in the London parks, is a very effective method of displaying the striking and brilliant beauty of the Coral Tree.

The plants may be increased by cuttings in spring in the same way as Dahlias. When the young shoots have grown 3-6 in. long in the warm greenhouse they may be detached at the very base with a sharp knife, and inserted singly in light sandy soil in small pots. If kept close and shaded and fairly moist for a short time the cuttings soon root, and may afterwards be potted on and hardened off for outdoor planting like the older plants. It may be added that frequent waterings with liquid manure during the growing season will be of great advantage to the plants, and a good mulching of well-rotted cow manure on top of the beds will also be highly beneficial. The other species of *Erythrina* require indoor treatment, although *E. herbacea*, with bright scarlet flowers, may be treated almost in the same way as *E. Crista-galli*.

APIOS (GROUND NUT).—A genus with 3 species of climbing perennials, having pinnate 3-7-foliolate leaves, and small stipules. Flowers axillary in panicles or clusters at the ends of the branches. Standard petal reflexed, ovate or roundish, longer than the obliquely ovate wings; keel elongated, much incurved, involute, or spirally twisted. Stamens 10, upper

one free. Pod linear, more or less sickle-shaped, flattish.

A. tuberosa (*Glycine Apios*).—An elegant light and graceful twining perennial, native of Pennsylvania, with eatable floury tubers, and pinnate leaves composed of 5 oblong lance-shaped leaflets. Flowers from July to September, deep orange, dull brownish-purple or pink, sweet-scented, in dense axillary racemes.

Culture and Propagation.—When grown in a sunny sheltered position in rich sandy loam, this plant is effective, but is not suitable for cold damp positions. It may be increased by dividing the tuberous roots in spring and also by seeds sown in cold frames as soon as ripe. It is on the whole better to raise plants from seeds, as the fleshy roots do not always separate well, and often die after division. The roots are eaten chiefly in winter time by the N. American Indians, and the idea was once entertained of growing them in Europe as a substitute for the Potato when the tubers of the latter were so much subject to disease.

CLADRASTIS.—A genus with two species of small trees, having oddly pinnate leaves, no stipules, and flowers in terminal panicles. Standard petal obovate-orbiculate, reflexed above the middle; wings obliquely oblong; keel slightly incurved, blunt. Stamens 10, free, or very shortly connate at the base. Pod linear, compressed, slender.

Culture and Propagation.—These plants grow best in sandy loam, and are suitable for shrubberies or perhaps in clumps on lawns. They may be increased by seeds which are freely produced in hot and favourable seasons; or by cuttings of the roots.

C. amurensis (*Maackia amurensis*).—An ornamental shrub about 6 ft. high, native of the Amoor Valley. Leaves with 3-4 pairs of ovate-oblong leaflets. Flowers late in summer, greenish-white, small, in long, dense, erect racemes.

Culture &c. as above.

C. tinctoria (*C. lutea*; *Virgilia lutea*). *Yellow Wood.*—A small N. American tree, with smooth pinnate leaves having 7-11 ovate leaflets. Flowers in May, white, in large drooping racemes from the ends of the branches. There is a form with variegated leaves which is said to be constant.

Culture &c. as above.

AMMODENDRON.—A small genus (3 species) of silvery silky shrubs, with abruptly pinnate leaves, having spiny stalks, and inconspicuous stipules. Flowers in terminal racemes. Standard petal roundish, recurved; wings obliquely oblong; keel incurved, blunt. Stamens 10, free. Pod linear or lance-shaped, flattened.

A. Sieversii (*Sophora bifolia*).—An elegant evergreen shrub 2-4 ft. high, native of Siberia. Leaves with 2 lance-shaped leaflets, silky, white on both sides. Flowers in June, purple, racemose.

Culture and Propagation.—This species thrives in well-drained sandy loam, and may be increased by seeds sown in spring out of doors, or in autumn as soon as ripe in warm sheltered spots. It may also be increased by layers during summer and autumn.

SOPHORA.—A genus with over 20 species of trees, shrubs, rarely herbs, having oddly pinnate leaves, and flowers in simple terminal racemes or panicles. Standard petal broadly obovate or roundish, often shorter than the oblong keel; wings obliquely oblong. Stamens 10, free, or rarely united in a ring at the base. Pod necklace-shaped, round, or slightly compressed, fleshy, leathery, or woody.

Culture and Propagation.—The Sophoras thrive in good sandy loam, and may be increased by imported seeds or by layering the branches. Cuttings of the roots may also produce young plants if placed in bottom heat at the beginning of the year. The weeping varieties are grafted on stocks of the commoner forms.

S. japonica (*Styphnolobium japonicum*).—*Chinese or Japanese Pagoda Tree.* A beautiful deciduous tree, 30-40 ft. high, native of China and Japan, and resembling the False Acacia (*Robinia*) in habit. The graceful bluish-green leaves have 9-13 oblong-ovate, acute leaflets. Flowers late in summer, white or creamy, small, in large, loose panicles at the ends of the branches. There is a not particularly beautiful variegated form, and also a drooping one (*pendula*), which are best grafted on the ordinary variety. A newer variety called *hybrida* only differs from the weeping form in the main branches spreading out horizontally, and in the branchlets being long, thin, and drooping.

Culture &c. as above. The Pagoda Tree and its weeping variety make

excellent lawn and park trees when sufficient space can be given them, the light airy effect of their foliage and the refreshing shade they give being highly appreciated.

S. platycarpa. — A Japanese species with the habit and general appearance of *S. japonica*, from which, however, it differs a good deal in the fruits.

Culture &c. as above.

S. tetraptera (*Edwardsia tetraptera*). A beautiful deciduous tree 6–12 ft. high, native of New Zealand, with leaves composed of 6–40 pairs of leaflets $\frac{1}{4}$ – $\frac{3}{4}$ in. long, varying from broadly obovate to linear oblong. Flowers in May, yellow, 1–2 in. long, in crowded racemes at the ends of

the branches. The variety *microphylla* is distinguished by its smaller leaflets.

Except in the very mildest parts of the country, perhaps, this species requires protection from frost. It is extremely elegant on account of its finely divided foliage, and its great masses of drooping yellow blossoms.

Culture &c. In most parts of the kingdom it requires the protection of a south wall, but may possibly succeed as a bush in the mildest parts of the south and west. It may be increased by seeds sown in gentle heat in spring; or by cuttings of the young shoots inserted in sandy soil in gentle heat; or by layering the branches in autumn.

SUB-ORDER II. CÆSALPINEÆ.

Flowers irregular, rarely regular. Sepals and petals 5, or the latter fewer by abortion, imbricate, upper one innermost. Stamens usually 10, usually free.

CÆSALPINIA.—A genus with about 40 species of pretty trees or shrubs, sometimes climbing, unarmed or with stiff sharp prickles. Calyx with 5 imbricated segments. Petals 5, usually roundish, imbricated. Stamens 10, free, bent down, filaments often hairy or glandular at the base. Pod ovate, oblong, lanceolate, or falcate, flattened.

C. japonica (*C. sepiaria*).—A Japanese prickly tree said to reach a height of 60 ft. in a wild state. Leaves twice pinnate, graceful, of a pleasing soft green tint, each pinna being composed of about 10 pairs of pinnules. Flowers in summer, deep yellow, with pinky anthers in the centre, and borne in racemes at the ends of the branches.

Culture and Propagation.—Cæsalpinias are usually grown under glass, but the species described above, if planted in light, sandy, peaty soil in sunny situations, has proved quite hardy in this country. It may be increased by imported seeds sown in cold frames on arrival or in gentle bottom heat; or by layering the branches in autumn. It is better to allow the prickly stems to remain unpruned except in cases where they become too dense and prevent the ripening influence of sunshine and air.

GYMNOCLADUS (KENTUCKY COFFEE TREE).—A genus with two species

described below with the generic characters as stated under *G. canadensis*.

G. canadensis.—An ornamental deciduous unarmed tree 30–60 ft. high, native of N. America. Leaves twice pinnate, often 3 ft. long, with 4–7 pairs of pinnæ, each one having 6–8 pairs of ovate leaflets. Flowers from May to July, polygamous, white, in clusters at the ends of the branches. Calyx with 5 narrow, nearly equal segments. Petals 4–5, oblong. Stamens 10, free, shorter than the petals, with thickish, hairy filaments. Ovary minute or wanting in the male flowers; sessile, with a thickened oblique stigma in the female and hermaphrodite ones. Pod oblong, somewhat falcate, thick, swollen or nearly round.

Culture and Propagation.—This tree loves a deep rich loamy soil and somewhat shady positions. It may be increased by cuttings of the roots inserted in bottom heat in early spring, or from imported seeds.

G. chinensis (*Soap Tree*).—A hardy Chinese tree having large twice pinnate leaves, composed of numerous bluntly oblong leaflets. The whitish flowers are produced at the ends of the branches in early summer. In China the women use the soft substance inside the seed pods for washing the face, hence the popular name.

Culture &c. as above for *G. canadensis*.

GLEDITSCHIA.—A genus with 4 or 5 species of ornamental deciduous trees, often armed with simple or branched rigid spines. Leaves twice pinnate, and also on the same tree abruptly pinnate. Flowers polygamous, in axillary clustered racemes or fasciated cymes. Calyx tube with 3-5 narrow subequal segments. Petals 3-5, sessile, unequal. Stamens 6-10, free. Pod ovate or elongated, flattened, leathery or fleshy.

Culture and Propagation.—The *Gleditschias* thrive in any fairly good soil, and may be increased by imported seeds. The plants are scarcely hardy enough to stand the rigours of a severe winter in the more northern parts of the British Islands.

G. macracantha.—A low-growing Chinese tree of spreading habit, and remarkable for the large branched spines on the trunk. The pinnate leaves are about 6 in. long, with a stout petiole and rachis channelled on the upper surface. The leaflets are fleshy in texture, bluntly oblong, with crenate-serrate edges, and of a rich deep green on the upper surface, but paler beneath.

Culture &c. as above. There used to be a fine specimen of this species in the gardens at Fulham Palace.

G. monosperma (*G. inermis*).—*Water Locust.*—A native of the United States 30-40 ft. high, with few slender 3-fid spines, ovate oblong acute leaflets, and greenish flowers in summer.

Culture &c. as above.

G. sinensis (*G. horrida*).—A Chinese tree 30-50 ft. high, with strong spines, ovate-elliptic, blunt leaflets, and greenish flowers in summer.

Culture &c. as above.

G. triacanthos (*Honey Locust*).—A native of the United States 30-50 ft. high, with strong simple or 3-fid spines, linear oblong leaflets, and greenish flowers in summer. There are a few varieties of this, including one without spines, and one with a drooping habit.

Culture &c. as above.

CASSIA.—A genus containing from 200 to 400 species (according to various authors) of ornamental trees, shrubs, or herbs, with abruptly pinnate leaves, and flowers in axillary or terminal panicles. Calyx segments 5, imbricated. Petals 5, imbricate spreading, nearly equal. Sta-

mens 3-10, unequal, some abortive. Pod round or flattened, woody, leathery, or papery.

Culture and Propagation.—The species described below are the only ones that may be grown outside in this country, and even *C. corymbosa* and *C. lævigata* require protection in winter, the first named certainly. The *Cassias* like a rich sandy loam and peat, and may be readily increased from imported seeds sown in heat, or by cuttings of the half-ripened shoots under glass during the summer months.

C. coquimbensis.—A pretty Chilean shrub with leaves 2-4 in. long composed of 4-6 pairs of elliptic oblong mucronate leaflets. The flowers are bright yellow, 1-1½ in. across, and are borne in corymbose racemes at the ends of the shoots in summer.

Culture &c. as above. This species is generally grown in a cool greenhouse, but would probably succeed in the open air in the mildest parts of the south and west, with a little protection in winter.

C. corymbosa.—A native of Buenos Ayres 6-10 ft. high, with smooth oblong lance-shaped, rather falcate leaflets, and a profusion of yellow flowers in summer.

Culture &c. as above.

C. lævigata (*C. herbertiana*).—A native of New Spain, about 3 ft. high, with smooth ovate lance-shaped pointed leaflets having an oblong acutish gland between each pair on the stalk. Flowers in summer, golden-yellow, numerous.

Culture &c. as above.

C. marilandica (*Wild Senna*).—A smooth herbaceous perennial, native of N. America, 2-3 ft. high, with lance-shaped oblong, blunt leaflets, and axillary racemes of yellow flowers late in summer.

Culture &c. as above. This plant should be grown in sheltered sunny spots, and may be increased by dividing the roots in spring, or from seeds sown as soon as ripe in cold frames.

CERATONIA (BEAN TREE; CAROB TREE; LOCUST TREE).—A genus with one species described below with the generic characters.

C. Siliqua.—A native of the Mediterranean region 30-50 ft. high, with abruptly pinnate evergreen leathery leaves and oval blunt leaflets. Stipules minute or none. Flowers late in summer, small, reddish,

polygamous, or diœcious, in short racemes. Calyx bell-shaped, with 5 short segments. Petals none. Stamens 5. Pod flattened, thickish, leathery, about 4 in. long, rusty colour, yielding a pulp which is eaten sometimes in this country by children.

Culture and Propagation.—This tree grows well in the mildest parts in warm sheltered spots. It may be increased by seeds or by cuttings inserted in sand under a glass during the late summer or autumn months, and protected during the winter.

CERCIS.—A genus with 6 or 7 species of unarmed, ornamental, deciduous trees or shrubs, distinguished by their simple kidney-shaped or cordate leaves, with 3 or many nerves. Flowers usually produced in clusters along the branches of one, two, or more years' growth. Calyx more or less bell-shaped, very short, and broadly 5-toothed. Petals 5, somewhat Pea-like. Stamens 10, free, bent down. Pod oblong, or broadly linear, flattened.

Culture and Propagation.—These trees like a deep rich sandy well-drained soil, and are fine plants for shrubberies or even alone on grass. When well established they are covered with flowers and may be justly regarded as amongst the finest flowering trees or shrubs in cultivation. They are usually increased by seeds sown in spring in gentle heat, but it takes 3 or 4 years to obtain a flowering plant. They are sometimes multiplied by layers. As old plants do not bear being transplanted very well, it is better to secure the permanent positions for Cercises while they are still young, say about 2 or 3 years old.

C. canadensis.—A Canadian tree 12–20 ft. high, with heart-shaped, pointed leaves, bearded in the axils of the veins beneath. The deep red and bright rose

flowers appear in May in clusters along the trunk and branches before the leaves are developed.

Culture *dc.* as above.

C. chinensis (*C. japonica*).—A Japanese and Chinese species closely resembling the preceding in habit and foliage, but has larger pink or deep purple-red flowers, and is probably not quite hardy except in the milder parts of the country. The roundish ovate leaves taper rather abruptly to a point, and are about 4 in. across, and there are about 6 or 8 flowers in each cluster.

Culture *dc.* as above.

C. Siliquastrum (*Judas Tree*; *Love Tree*).—A native of S. Europe 20–30 ft. high, with smooth, bluntly heart-shaped, emarginate leaves 3–4 in. across and of a blue-green hue, and clusters of bright purple, pale rose or whitish flowers in May. There is a form of the Judas tree with variegated leaves.

Culture *dc.* as above. In unfavourable parts of the country this tree is best against a wall.

The following species of *Cercis* are known to botanists, but are not yet cultivated in the British Islands.

C. Griffithi.—A trailing shrub native of Afghanistan where it grows at an elevation of over 10,000 ft. It has smooth kidney-shaped emarginate leaves.

C. racemosa.—A distinct and handsome Chinese tree about 20 ft. high, with roundish leaves 2–4 in. long and broad, downy beneath. From 10 to 30 flowers are borne on racemes about 4 in. long.

C. texensis.—A shrub or small tree, native of the Rio Grande valley, and thus probably somewhat too tender for outdoor cultivation in the British Islands. It has heart-shaped reniform leaves, and clusters of rosy-pink flowers.

XXXIX. ROSACEÆ—Rose Order

A large order containing 1,000 species or more of erect or prostrate herbs, shrubs or trees, rarely climbers. Leaves various, simple or compound, alternate or rarely opposite, stalk often dilated at the base. Stipules 2, free or adhering to the leaf stalk. Flowers usually regular and hermaphrodite. Calyx free or adnate to the ovary, usually 5-lobed, imbricated and persistent. Petals 5, rarely none, inserted under the margin of the disc, imbricate. Stamens usually numerous, inserted with petals. Carpels 1 or many, free or united, and more or less adnate to the calyx-tube. Fruit various, superior, or more

or less inferior, naked or enclosed by the persistent calyx-tube. Besides the Rose, the Apple, Pear, Plum, Cherry, Raspberry, Strawberry, Peach, Nectarine, Apricot, Almond &c. belong to this important order. Owing to the great range of variation, the order has been divided into 10 tribes, which however are not all represented out of doors in this country.

Tribe I. PRUNÆ.—Trees or shrubs with simple leaves, often serrate. Calyx usually deciduous. Carpels 1. Fruit a drupe. Flowers regular. Stamens usually in 3 whorls of 5 or 10.

PRUNUS.—A genus containing about 80 species of evergreen or deciduous trees or shrubs, with alternate, simple, often serrulate leaves. Flowers solitary, racemose, or in fasciated corymbs, white or rose. Petals 5. Stamens 15–20.

Besides the Plums proper, this genus now includes the Almonds, Peaches, and Nectarines (*Amygdalus*); the Apricot (*Armeniaca*); the Cherry (*Cerasus*), and the Cherry Laurels (*Lauro-cerasus*).

Just here these plants are regarded solely from the point of view of beautiful ornamental flowering trees. The Almonds, Cherries, Plums, and Peaches are not only beautiful flowering trees, but they bloom at a period when they are most wanted, that is, from January to June. Of late years this fact has been appreciated to such an extent that small plants have been grown in pots for conservatory decoration in winter. The protection afforded by the glass alone is sufficient to make them flower earlier than out of doors.

As outdoor plants they may be utilised in shrubberies, or as isolated specimens in grass or even on lawns. Indeed, there are so many beautiful hardy flowering trees and shrubs now (see list, p. 107) that it is astonishing they are not more extensively planted instead of the cheerless and flowerless shrubs so often seen.

Culture and Propagation.—Speaking generally all the Plums, Cherries, Almonds and Laurels described below will flourish in ordinary good and well-drained garden soil, and in open but somewhat sheltered situations. Where it is possible to give particular attention to their cultivation, the cultural practice as detailed under the Plum (p. 1069), the Cherry (p. 1075), the Peach and Nectarine (p. 1078) may with advantage be adopted. It is not, however, necessary to practise all the details given under each of these fruits, as the objects in view are entirely different. In one

case the aim of the gardener is to secure the finest possible crop of fruit; in the other he seeks only to obtain a beautiful well-shaped tree or shrub which shall bear abundance of blossom, and give the garden, park, and landscape generally a charming aspect. To secure this, ordinary good cultivation mixed with common sense will as a rule be sufficient. Pruning may be practised to a moderate extent, but only when the branches are apt to become too dense so as to exclude light and air from the interior of the tree, and prevent the proper ripening of the wood.

As for propagation, this is effected by seeds, budding, grafting, layering, and cuttings, but it will be better for the amateur as a rule to obtain established plants from a nurseryman. There is, however, no reason why he should not sow his own seeds as soon as ripe in sheltered spots in ordinary good soil. Plants are easily obtained in this way, but it takes a long time before they reach the flowering stage. By budding or grafting some of the best flowering Plums or Cherries on stocks of any of the ordinary kinds raised from seeds, flowering specimens will be obtained in a shorter time, and any particularly rare variety can also be more quickly increased in numbers by this process. A watch, however, must be kept to prevent suckers of the undesired stock springing from the base and absorbing the nourishment required by the choicer graft.

Layering is another operation easily performed with most of the species. By pegging branches down as explained at p. 59, plants will in due course be obtained on their own roots, and with such any suckers from the base will of course be the same as the variety.

Cuttings of the ripened branches 9 in. to 1 ft. long will also root freely with many kinds if inserted 3 or 4 in. deep in light rich and sandy soil about September or October in warm and sheltered spots, or under handlights in the case of kinds

that may prove to be a little tender in winter. The soil should be pressed firmly round the cuttings so as to prevent them being lifted out or loosened by the action of frost.

Although doubtless convenient from a botanical point of view to have the Plums, Almonds, Cherries, and Cherry Laurels sunk under the genus *Prunus*, from a popular and gardening point of view it is perhaps not quite so desirable. It may therefore be useful to give a list as set forth in the 'Kew Handbook' showing the natural groups to which the various species described below belong.

THE ALMONDS AND PEACHES (*Amygdalus*)

Leaves conduplicate in bud (i.e. folded with the 2 halves face to face). Flowers nearly sessile, expanding before the leaves. Calyx short or elongated. Drupe often large, velvety; flesh firm; stone wrinkled and full of small holes.

- | | |
|---------------------|----------------------|
| P. <i>Amygdalus</i> | P. <i>nana</i> |
| P. <i>Boissieri</i> | P. <i>orientalis</i> |
| P. <i>dauriana</i> | P. <i>Persica</i> |
| P. <i>incana</i> | P. <i>Simoni</i> |

THE APRICOTS (*Armeniaca*)

Leaves convolute in bud (i.e. rolled up from one edge to another). Flowers sessile or stalked, expanding before the leaves. Calyx short or bell-shaped. Drupe velvety; flesh pulpy; stone smooth with a furrow on each side.

- | | |
|---------------------|---------------------|
| P. <i>Armeniaca</i> | P. <i>Mume</i> |
| P. <i>Brigantia</i> | P. <i>tomentosa</i> |
| P. <i>dasycarpa</i> | P. <i>triloba</i> |

THE PLUMS (*Prunus*)

Leaves convolute in bud. Flowers stalked, solitary or in pairs, expanding before or at the same time as the leaves. Calyx short, obconical or hemispherical. Drupe quite smooth, often with a glaucous 'bloom'; stone compressed, oblong or ovoid, smooth or wrinkled.

- | | |
|--------------------------|----------------------|
| P. <i>alleghaniensis</i> | P. <i>communis</i> |
| P. <i>americana</i> | P. <i>divaricata</i> |
| P. <i>angustifolia</i> | P. <i>insititia</i> |
| P. <i>cerasifera</i> | P. <i>spinosa</i> |

*** THE CHERRIES (*Cerasus*)**

Leaves conduplicate in bud. Flowers either solitary or in clusters or umbels, expanding before or at the same time as the leaves. Calyx short, obconical or elongated, sometimes cylindrical. Drupe

quite smooth, not glaucous; stone smooth or wrinkled.

- | | |

| P. <i>Cerasus</i> | P. <i>prostrata</i> |
| P. <i>Chamaecerasus</i> | P. <i>pseudo-cerasus</i> |
| P. <i>humilis</i> | P. <i>Puddum</i> |
| P. <i>Jacquemonti</i> | P. <i>pumila</i> |
| P. <i>japonica</i> | P. <i>serrulata</i> |
| P. <i>Maximowiczii</i> | |

**** THE BIRD CHERRIES (*Padus*)**

- | | |
|--------------------|----------------------|
| P. <i>Capollin</i> | P. <i>mollis</i> |
| P. <i>cornuta</i> | P. <i>Padus</i> |
| P. <i>depressa</i> | P. <i>serotina</i> |
| P. <i>Mahaleb</i> | P. <i>virginiana</i> |

THE CHERRY LAURELS (*Laurocerasus*)

Leaves conduplicate in bud. Flowers in racemes from the axils of the leaves or the ends of the branches. Calyx short, obconical. Drupe quite smooth, very rarely glaucous, oblong or round; stone smooth or wrinkled.

- | | |
|------------------------|----------------------|
| P. <i>ilicifolia</i> | P. <i>lusitanica</i> |
| P. <i>Laurocerasus</i> | |

P. *acida* (*Cerasus acida*).—A beautiful dwarf Cherry, native of Europe, and interesting not only for its ornamental flowering properties but also as one of the parents of the fruiting varieties. The beautiful white flowers are borne from May to September, and are well displayed among the small deep green glossy leaves. There is a double-flowered variety (*flore pleno*) and also one called *semperflorens*, with a drooping habit.

Culture &c. as above.

P. *alleghaniensis*.—A Pennsylvanian shrub 4-6 ft. high or more, having pure white flowers $\frac{1}{2}$ in. across, changing to pink, followed by nearly round, bluish-purple fruit, useful for preserving.

Culture &c. as above.

P. *americana* (*P. nigra*).—*American Wild Yellow or Red Plum.*—A handsome N. American tree 8-20 ft. high, with more or less ovate, pointed, coarsely toothed leaves. Flowers in April and May, pure snowy-white. Fruits yellow, red, or orange, less than 1 in. in diameter, pleasantly flavoured.

Culture &c. as above.

P. *Amygdalus* (*Amygdalus communis*). *Common Almond.*—A beautiful tree 10-30 ft. high, native of Barbary, with oblong

lance-shaped serrulate leaves. Flowers early in March, white or rose, in great profusion before the leaves. Fruit compressed, egg-shaped, woolly. There are several varieties all beautiful, among them being *amara* (Bitter Almond), with large white flowers rosy at the base; seeds bitter: *dulcis* (Sweet Almond), flowers red, earlier than the type; leaves grey-green; seeds sweet: *flore pleno*. flowers double, flesh-colour, rosy in bud; leaves oval elliptic, pointed: *fragilis*, leaves shorter than in the type; flowers pale rose: *macrocarpa*, leaves broader than in the type, pointed; flowers blush-rose, about 2 in. across with broadly obovate wavy petals, and large fruits: and *pendula*, drooping in habit.

Culture &c. as above, p. 356.

P. angustifolia (*Chickasaw Plum*).—A native of the United States, where it attains a height of 15-20 ft. It has leaves 3 in. long, and white or creamy-tinted flowers, each about $\frac{1}{2}$ in. across. There are several varieties, including a variegated one; but they are not yet well-known in this country.

Culture &c. as above, p. 356.

P. Armeniaca (*Armeniaca vulgaris*).—*Common Apricot*.—A native of N. China, 15 ft. or more high, with ovate, heart-shaped, smooth, serrated leaves. Flowers in February and March before the leaves, pinkish-white, stalkless. There is a double-flowered variety.

Culture &c. as above, p. 356.

P. Avium (*Cerasus Avium*).—*Wild Cherry* or *Gean*.—A beautiful British tree 20-30 ft. high, with oval lance-shaped, pointed, serrated, somewhat drooping leaves, slightly downy beneath, with 2 glands at the base. Flowers in April and May, before the leaves, white. Fruit roundish ovoid, depressed, black, with succulent sugary flesh adhering to the stone. This is one of the parents of the fruiting Cherries. A hybrid named *græca* has been obtained by crossing it with *P. Mahaleb*.

Culture &c. as above. The variety *decumana* is a striking tree with leaves 6-8 in. long, *Jubiana* (*St. Julian's Cherry*) and its sub-varieties have large beautiful blush-tinted flowers appearing with the leaves, and ovate heart-shaped, sweet-flavoured fruits; *multipler* has pure white double flowers; *nana* is dwarf

in habit; *laciniatâ* has cut leaves; and *pendula* has a drooping habit.

P. biferum.—A vigorous tree of garden origin remarkable for bearing flowers and fruit at the same time. Leaves broadly oval, narrowed at both ends. Flowers in April, large, white, on the old wood, in small umbellate clusters; the later ones appearing on the young wood in short racemes.

Culture &c. as above, p. 356.

P. Boissieri (*Amygdalus Boissieri*).—An ornamental Almond, native of Asia Minor, not yet well known. Leaves 1 in. long, elliptic, leathery. Flowers in early spring, pale flesh-colour, numerous.

Culture &c. as above, p. 356.

P. Brigantiaca (*Armeniaca Brigantiaca*).—A South European Apricot 6-8 ft. high, with rather heart-shaped, pointed, sharply and numerously toothed leaves. Flowers in March, before the leaves, white or pink, almost sessile, in heads, followed by small yellow Apricot-like fruits.

Culture &c. as above, p. 356.

P. Capollin.—A Mexican Cherry 30-35 ft. high in a wild state. Leaves dark glossy green, loose, drooping. Flowers white, in erect racemes. Fruit round, dark red.

Culture &c. as above, p. 356.

P. caroliniana.—A pretty North American Cherry, with evergreen oblong lance-shaped mucronate smooth, rather leathery, almost entire leaves. Flowers in May, rather large, white, in dense axillary racemes.

Culture &c. as above, p. 356.

P. cerasifera (*Myrobalan*).—The native country of this showy Plum is unknown but it is supposed to be indigenous to the Caucasus. It forms a very handsome round-headed tree about 20 ft. high, with elliptic obovate acute, serrulate leaves, smooth beneath. Flowers in March and April before the leaves, white, about 1 in. across, in clusters on short twigs. Fruit red, round, yellow-fleshed. *P. Pissardi* (or *P. cerasifera atropurpurea*) is a beautiful variety of Persian origin. It has glossy, blackish-purple twigs, and smooth, broadly oval, reddish-purple leaves; flowers white; fruit small, deep red or purple, sugary when ripe. The foliage is now extensively used by florists for floral decorations.

The variety *contorta* has spirally

twisted leaves, and the tree is more fastigiate in habit than the type.

Culture &c. as above. The typical species is also known as *P. mirobalana* and *Cerasus myrobalanos*, and for this reason has been a good deal confused with another Plum called the 'Mirabelle,' which is a variety of the common wild Plum, *P. communis*.

P. Cerasus (*Cerasus vulgaris*; *C. Caproniana*).—*Wild or Dwarf Cherry*.—A small British tree, 15–20 ft. high, with red bark, slender drooping branches, and dark blue-green, oblong obovate, or elliptic crenate-serrate, smooth leaves. Flowers in May, pure white. The variety *Bigarella* (*Cerasus duracina*) is supposed to be a parent of the Bigarreau and Heart Cherries.

Many fine varieties are known, the best perhaps being:—*Flore pleno*, a distinct and beautiful double-flowered variety; *multiplex* (or *ranunculiflora*), also a fine double-flowered form; and *Rhevi fl. pl.*, another variety with pure white long-stalked double flowers in great profusion. *Semperflorens*—the All Saints, Ever-Flowering, or Weeping Cherry—is a beautiful variety with gracefully drooping branches; and *persiciflora* has double white flowers tinged with rose.

Culture &c. as above, p. 356.

P. Chamæcerasus (*Cerasus chamæcerasus*).—*Ground Cherry*.—A dwarf European Cherry 10 ft. or more high, with obovate, shining, crenate, bluntish, smooth, rather leathery leaves. Flowers in May, white, about $\frac{3}{4}$ in. across, usually in sessile clusters. Fruit round, reddish-purple, acid. The variety *pendula* has a drooping habit, and there is also a form with variegated leaves.

Culture &c. as above, p. 356.

P. Cocumilio.—An ornamental Plum from S. Italy, with obovate serrate leaves and masses of white-flowers in spring, succeeded by beautiful yellow fruits.

Culture &c. as above. Although a native of a warmer climate than our own, this species seems to be quite hardy. It grows about 20 ft. high, and one of the finest specimens in the country is to be found in the Oxford Botanic Gardens, where it flowers and fruits almost every year.

P. communis (*Common Plum*).—An ornamental tree 10–15 ft. high, with ovate or oblong lance-shaped leaves, downy

beneath when young. Flowers in March and April, white. The variety *Pruneauliana* has beautiful masses of white flowers in April, and there is also a double-flowered form of it. The Sloe and Blackthorn (*P. spinosa*), the Bullace (*P. insititia*) and the Wild Plum (*P. domestica*) are all varieties of *P. communis*, and in conjunction with it have probably produced the well-known cultivated Plum (see p. 1069). The variety *juliana* is much used as a stock for budding, as is also the one known as the 'Mirabelle' Plum alluded to above under *P. cerasifera*.

The double-flowered Blackthorn (*P. spinosa fl. pl.*) is a pretty March-blooming shrub, and a variety of the common wild Plum called *Plantieri* is very ornamental owing to its wealth of semi-double pure white flowers, succeeded by black and good flavoured fruits.

Culture &c. as above, p. 356.

P. dasycarpa (*Armeniaca dasycarpa*). A pretty Chinese Apricot 10–15 ft. high, with dark glossy green, ovate pointed serrate leaves; the white flowers appear in great profusion in March and April before the leaves unfold.

Culture &c. as above, p. 356.

P. davidiana (*Persica davidiana*).—A very ornamental Chinese tree, with wavy serrated leaves narrowed towards the base, and pale rose or white flowers, often produced as early as January in mild winters, and in great profusion. The pure white form is called *alba*, and the pink form *rubra*.

Culture &c. as above, p. 356.

P. demissa (*Cerasus demissa*).—A species of Bird Cherry, native of the United States, and closely related to *P. virginiana*. It may, however, be distinguished from the latter species by its thicker and more downy leaves, which are rounded or somewhat heart-shaped at the base. The pure white flowers appear in April and May on racemes 3–6 in. long.

Culture &c. as above, p. 356.

P. divaricata.—A graceful Caucasian tree 10–25 ft. high, with lance-shaped and ovate leaves 2 in. long, often nearly cordate at the base, smooth beneath. Flowers in March and April when the tree is in leaf, white, $\frac{3}{4}$ in. across, and borne in such profusion as to almost hide the branches.

This species comes very near *P. cerasifera*, but the flowers open a little later than that species. It makes a splendid

subject for the lawn and is one of the most effective spring-flowering trees in cultivation.

Closely related is *P. baldschuanica* from Bokhara with obovate elliptic coarsely serrate leaves and red flowers.

Culture &c. as above, p. 356.

P. humilis (*P. Bungei*).—A small tree or bush 4–10 ft. high, native of China. The ovate pointed leaves are $1\frac{1}{2}$ –2 in. long, with glandular and ciliate stipules. The beautiful rosy-pink flowers, about $\frac{1}{2}$ in. across, are borne freely in April and May.

Culture &c. as above, p. 356.

P. ilicifolia (*Cerasus ilicifolia*).—A beautiful Californian Cherry Laurel, with shining, evergreen, sharply toothed leaves, more or less Holly-like. Flowers in spring, small, white, in erect or nodding racemes 1–3 in. long. Fruit usually red, sometimes dark purple or black, about half an inch in diameter.

Culture &c. as above. This very distinct species is best near the shelter of a wall in warm, dry situations. It may not be hardy in bleak parts of the country.

P. incana (*Amygdalus incana*).—A handsome Caucasian Almond 2–4 ft. high, with obovate, serrate leaves, woolly, white beneath. Flowers in March and April, deep rosy-red, solitary, followed by downy flattened fruits. This species is closely related to *P. nana*.

Culture &c. as above, p. 356.

P. Jacquemonti.—A pretty Cherry from N. India, where it grows at an altitude of 6,000–12,000 ft. The ovate pointed leaves are $1\frac{1}{2}$ –2 in. long, and somewhat downy when young. Flowers bright rosy-pink, about $\frac{1}{2}$ in. across, borne in great profusion on the previous year's growths about April and May.

Culture &c. as above, p. 356.

P. japonica (*P. sinensis*).—A charming Chinese Plum with oblong pointed, serrulate leaves, and clusters of small white flowers in spring. Fruit small, round, deep red, of a peculiar but agreeable flavour. The variety *flore pleno* has beautiful double flowers $1\frac{1}{2}$ in. across, white, more or less tinted with rose. A hybrid called *reptans* has been raised between *P. japonica* and *P. pumila*. It has somewhat trailing branches and red flowers. A form called *stricta* has erect branches and white flowers.

Culture &c. as above. In about two

years flowering plants may be obtained from layers, but cuttings of the ripened shoots will also root in sandy soil under a handlight.

P. Laurocerasus (*Cerasus Laurocerasus*).—Common or Cherry Laurel.—A beautiful and well-known evergreen shrub 6–10 ft. high, native of the Levant. Leaves oblong lanceolate, serrate, with 2–4 glands beneath. Flowers in April and May, small, white, in racemes. There are many good varieties, among them being:—*angustifolia*, with narrow leaves; *camelliaefolia*, Camellia-leaved; *caucasica*, a sturdy variety called the 'Spanish Laurel'; *colchica*, very free-flowering; *rotundifolia*, round-leaved, much grown and planted; *variegata*, with variegated foliage; and *shipkaensis*, said to be hardiest of all. *Parvifolia* is a distinct narrow-leaved variety sometimes known as *Hartoghia capensis* in gardens.

Culture and Propagation.—Cherry Laurels will grow in almost any soil, and are mostly used for rough shrubberies. In such places they are as a rule much ill-treated and hacked about with knife and saw. Grown in sheltered but open spaces the Cherry Laurel would have a much handsomer appearance.

It may be increased by layering the lower branches in autumn, or by inserting cuttings of the ripened shoots in nicely prepared sandy soil in sheltered spots about September.

P. lusitanica (*Cerasus lusitanica*).—*Portugal Laurel*.—A beautiful Portuguese tree 10–20 ft. high, with evergreen ovate-lance-shaped, serrated leaves. Flowers in June, white, in drooping axillary racemes. Fruit ovoid, red when ripe. The variety *myrtifolia* is a dwarf, compact, upright-growing form with smaller Myrtle-like leaves; *azorica* has larger leaves and flowers. There is also a rare variety with variegated foliage.

Culture &c. as above for the Cherry Laurel.

P. Mahaleb (*Cerasus Mahaleb*).—The Mahaleb or Perfumed Cherry attains a height of 20–30 ft. in its wild state in Central and S. Europe, and supplies a red, hard, sweet-scented wood. Leaves broad, roundish, cordate, toothed. Flowers in April and May, white, in somewhat corymbose, leafy racemes. The variety *pendula*, with leaves 2 in. long, has a loose but not altogether drooping habit of

growth and produces immense masses of sweet-scented blossoms; *variegata* has clean, silvery, variegated leaves, very ornamental. There are other varieties such as *globosa*, *chrysoarpa*, and *monstrosa* in cultivation, but they are not well known.

Culture &c. as above.

P. Maximowiczii.—A newly introduced Cherry, native of Japan and Corea, where it attains a height of 25–30 ft. and has a rusty down covering the under surface of the elliptic obovate, coarsely toothed leaves as well as the young shoots. The white flowers, each about $\frac{3}{8}$ in. across, are produced in May on racemes 3–4 in. long, remarkable for their coarsely toothed bracts.

Culture &c. as above, p. 356.

P. miqueliana (*Cerasus herincquiana*).—A Japanese species related to *P. pendula*, from which, however, it differs in having darker coloured shoots, which, when young, are covered with a soft down, as are also the broader, thinner, and the more deeply and irregularly cut leaves, at the base of which are 2 orange glands. The flowers are pale pink or nearly white, the petals being narrowly obovate.

Culture &c. as above. Although cultivated at Kew this species is not yet well known.

P. mollis (*P. pattoniana*; *Cerasus mollis*).—A Bird Cherry 20–30 ft. high, native of the Western United States, and easily recognised by its blunt elliptic leaves, the under surface of which is covered with down. The white flowers, each about $\frac{1}{2}$ in. across, are borne in corymb-like racemes in May, and are in due course succeeded by reddish fruits.

Culture &c. as above, p. 356.

P. Mume.—A Japanese Apricot with obovate or broadly elliptic, long pointed, doubly serrate leaves, rounded at the base, and smooth or downy beneath. Flowers early in the year before the leaves, red or white, usually twin. There are several forms with single and double flowers; also one with a drooping habit.

Culture &c. as above.

P. nana (*Amygdalus nana*; *A. besseriana*).—A beautiful dwarf Almond 2–3 ft. high, native of Tartary, with smooth, oblong linear, serrated leaves, narrowed at the base. Flowers in Febru-

ary and March, rosy, one on a stalk, but in great profusion.

Culture &c. as above. This species is more easily increased by layering than any other means.

P. orientalis (*Amygdalus argentea*).—*Silver Almond.*—A distinct-looking small-growing Almond native of Western Asia, remarkable for the silvery down which covers its short ovate leaves. It does not flower very freely owing to the unfavourable weather in the early period of the year, and it can only be considered quite hardy in the mildest parts of the British Islands.

Culture &c. as above.

P. orthosepala.—A compact-growing twiggy shrub 4–5 ft. high, native of Texas, having white flowers with projecting orange-coloured stamens. The dark blue or nearly blackish fruits are covered with a glaucous 'bloom,' and have a thick juicy yellow flesh of good flavour and quality.

Culture &c. as above. This is a comparatively new species, and is still practically unknown in a cultivated state.

P. Padus (*Cerasus Padus*).—*Bird Cherry* or *Hagberry.*—A beautiful tree 10–30 ft. high, native of the British Islands, Europe, N. Africa, and Asia. Leaves 2–4 in. long, elliptic or obovate, sharply and double serrate, unequally cordate at the base. Flowers in May, $\frac{1}{2}$ – $\frac{3}{4}$ in. across, white, in erect (then drooping) racemes 3–8 in. long.

There are many varieties, such as *argentea*, leaves silver blotched; *acubæfolia*, Aucuba-like leaves; *bracteosa*, with long bracts; *flore pleno*, a splendid double-flowered form; *heterophylla*, leaves various; *parviflora*, smaller flowers than in type; *rubra*, reddish flowers; *stricta*, with flowers in erect racemes. There is also a Manchurian variety with fine racemes of flowers which open some time before the ordinary form. *P. cornuta* from the Himalayas is a form of the Bird Cherry with larger, broader, and stouter red-stalked leaves than the native species.

Culture &c. as above.

P. pendula (*Cerasus pendula*).—A beautiful drooping Japanese Cherry, with leaves similar in shape to those of the Common Cherry (*P. Cerasus*). Flowers

in March and April, beautiful soft rose or white, in great profusion.

Culture and Propagation.—This species should be planted in warm sheltered spots. It is said to come true from seed, but is often grafted on stocks 5–6 ft. high, to display its drooping character to advantage.

P. pennsylvanica (*American Wild Red Cherry*).—A graceful N. American tree 20–30 ft. high, with light reddish-brown bark, and oblong lance-shaped, pointed leaves, finely and sharply serrated, shining green and smooth on both sides. Flowers in May, white, many in a cluster. Fruit small, light red, round, sour.

Culture &c. as above.

P. Persica (*Persica vulgaris*).—*The Peach*.—The wild Peach is supposed to be of Asiatic origin. It grows about 15 ft. high, has smooth, lance-shaped, serrated leaves, and light or dark red, stalkless flowers in April and May.

There are several varieties, that with double flowers, *flore pleno*, being one of the best; the purple-leaved variety known as *foliis rubris* is pretty and distinct, and *magnifica* is a newer form surpassing in beauty any of the others. The variety *lævis* is the origin of the Nectarine, and is distinguished from the Peach by its smooth-skinned and rather firmer fruit.

Culture &c. as above. The treatment of the cultivated Peach and Nectarine will be found at p. 1078.

P. prostrata.—A rare and lovely dwarf Cherry, native of the mountains of the Levant, with long slender branches arching outwards and downwards to the ground. The broadly ovate finely toothed leaves are 1½–2 in. long on cultivated plants, but are usually much smaller in wild specimens. The flowers, which are borne in great profusion on very short stalks, are about ¼ in. across, and of a bright rose colour.

Culture &c. as above, p. 356.

P. pseudo-cerasus (*P. paniculata*).—*Bastard Cherry*.—A pretty Chinese and Japanese Cherry 6–20 ft. high, with downy branches and flower stalks, and obovate pointed, serrated leaves. Flowers in April and May, white or rosy-white, each about 2 in. across, in racemes. Fruit pale red, small, with a pleasant acid flavour.

The double-flowered varieties are far more beautiful and valuable ornamental trees than the type. In *flore pleno* the flowers are white at first, but are afterwards suffused with pink. *Watereri* is another fine double variety.

Culture &c. as above.

P. Puddum.—A rare Cherry 10–20 ft. high, native of the Bhotan and Sikkim Himalayas, where it grows at an elevation of 5,000–8,000 ft. The smooth serrate leaves are 3–4 in. long, and the beautiful soft rosy flowers, each about ¾ in. across, are borne in great profusion about April and May on leafless twigs. The red Cherry-like fruits are produced fairly freely in warm and sheltered spots.

Culture &c. as above.

P. pumila (*Cerasus depressa*; *C. glauca*).—A pretty N. American Cherry 3–6 ft. high, having dark coloured twigs clothed with bright green oblong leaves about 2 in. long. The white flowers are produced in great abundance during April and May, but in some varieties they are purer and prettier than in others.

Culture &c. as above, p. 356. This species is easily increased by cuttings of the well-ripened shoots inserted in light sandy soil in September, at which period the lower branches also may be layered. Grown in masses or groups this species looks very effective.

P. serotina.—A rather pretty Bird Cherry 20–40 ft. high, native of Canada and Central America, where it sometimes reaches a height of about 100 ft. The dark green glossy leaves resemble those of the Portugal Laurel (*P. lusitanica*), and readily distinguish it from the other Cherries. The whitish flowers appear early in June, and are borne in great profusion on racemes 3–6 in. long. The variety *pendula* differs from the type in having a drooping habit of growth.

Culture &c. as above, p. 356.

P. serrulata (*Cerasus serrulata*; *C. Sieboldii*).—*Double Chinese Cherry*.—A beautiful Chinese tree 15 ft. high, with smooth, obovate-acute, sharply serrated leaves. Flowers in April, pale white or rose-tinted, double, in clusters. The single-flowered type does not appear to be in cultivation.

Culture &c. as above, p. 356.

P. Simoni.—An erect-growing, somewhat fastigate Chinese Almond with

leaves like those of the Common Almond (*P. Amygdalus*). Flowers in February and March, white, succeeded by deep purple fruits.

Culture &c. as above, p. 356.

P. subhirtella.—A pretty erect-growing Japanese Cherry closely related to *P. pendula*. It has rather dull green ovate-pointed leaves more or less hairy on both sides. The beautiful soft rosy flowers, about $\frac{1}{2}$ in. across, are borne in March and April, and give a very handsome appearance to the tree.

Culture &c. as above, p. 356.

P. tomentosa.—A pretty Chinese and Japanese shrub 5-9 ft. high, with leaves and branches more or less covered with soft downy hairs, and having large white, flesh-tinted flowers produced early in March and April, succeeded later on by Cherry-like fruits about $\frac{1}{2}$ an inch in diameter. This species is not yet well known but has been proved quite hardy at Kew. It is interesting from the fact that it seems to stand between the Cherries and Apricots, thus linking the two.

Culture &c. as above, p. 356.

P. triloba fl. pl. (Amygdalopsis Lindleyi; Prunopsis Lindleyi).—This is perhaps the very best of all the beautiful flowering Plums, Cherries, or Almonds. It is a native of China and grows 10-15 ft. high, and is easily recognised by its 3-lobed leaves which appear after the flowers. The latter are produced in such profusion at the end of March or early in April as to practically cover the tree; they are usually white although tinged with rose when opening, double, and about $1\frac{1}{2}$ -2 in. across. The single-flowered variety is not yet well known, although it has recently been introduced. It has smaller, rosy-white flowers.

Culture &c. as above.

Tribe II. SPIRÆA.—Shrubs or trees. Calyx lobes usually persistent. Stamens 10 or more. Carpels 1-8, not enclosed by the calyx tube.

SPIRÆA (MEADOW SWEET).—A genus with about 50 species of beautiful herbs, shrubs, or undershrubs, mostly deciduous. Leaves alternate, simple, pinnate, or 2-3-ternate. Stipules free, or sheathing and adnate to the leaf stalk. Flowers axillary or terminal, variously clustered, hermaphrodite or polygamous-dioecious. Sepals and petals 4-5. Stamens

P. virginiana (Cerasus virginiana).—*Choke Cherry*.—A native of the United States, where it is said to grow from 20 to 80 ft. high. Leaves smooth, oblong, pointed, doubly serrate. Flowers in May and June, white, in long, erect racemes. Fruit round, red.

Culture &c. as above.

P. Watsoni (Sand Plum).—A recently introduced compact-growing twiggly shrub 3-12 ft. high, native of the United States. Its beautiful white or blush blossoms appear about the middle of May, 3 or 4 in cluster, and in such profusion that the twigs are almost completely hidden from view. The flowers are about $\frac{1}{2}$ in. across, and emit a delicate fragrance. They are succeeded by bright orange-red shining fruits in warm and sheltered localities in favourable seasons.

Culture &c. as above.

NUTTALLIA (OSOBERY).—A genus with only one species described below, with the generic characters:—

N. cerasiformis.—A rather pretty Californian shrub, 6-12 feet high, with obovate, entire, deciduous leaves. Flowers in March and April, polygamous-dioecious, white, small, in drooping racemes, sometimes before the leaves appear. Calyx campanulate, 5-lobed. Petals 5, oblong, shortly clawed. Stamens 15, the 10 upper ones inserted on the calyx, the 5 lower deflexed inserted in the middle of the tube. Fruit Plum-like, purple, about 1 in. long and $\frac{3}{4}$ in. broad, rarely ripens in even the most favoured parts of the British Islands.

Culture and Propagation.—This species grows well in ordinary soil and may be increased by the suckers from the roots, or from imported seeds. Cuttings of the more or less ripened shoots may also be rooted in sandy soil under a hand-light. By layering the lower branches in autumn fresh plants may also be secured.

20-60, inserted in 1 or more series or bundles round the mouth of the calyx tube. Carpels usually 5, dehiscent.

Culture and Propagation.—Spiræas may roughly be divided into two groups—shrubby-stemmed and herbaceous, the stems and leaves of the latter dying down in winter, the former losing only their leaves. The herbaceous kinds as a rule

like a moist, loamy soil, and thrive near water. They may be increased by dividing the rootstocks in autumn or spring or by sowing the seeds as soon as ripe in cold frames.

HERBACEOUS SPIRÆAS

S. Aruncus (*Goat's Beard*).—A bold and beautiful herbaceous plant, 3-5 ft. high, native of North Europe, Asia and America, with thrice pinnate leaves a foot long, and lance-shaped oblong or ovate lance-shaped serrated leaflets. Flowers in June and July, white, dioecious, in many slender spikes thrown well above the foliage. *Americana* is a variety in which the interrupted male flowers are scarcely larger than the female ones, and the plant in some parts of the world, e.g. the Japanese Alps, attains only 1 ft. in height. The variety *trifernata* has thrice ternate leaves, often covered with an ashy down beneath.

Culture and Propagation.—This is a fine plant for massing in the herbaceous border or for planting in beds by itself on the grass. It flourishes in both open and sunny situations and also in shade, providing there is always plenty of air, and the plants are not suffocated with overhanging branches of trees or placed too close to other plants. It may be increased by division in September or early in spring, or seeds may be sown as soon as ripe in cold frames, or in the open border, afterwards pricking off the seedlings the following spring when large enough, and in mild weather. When the plants are coming into bloom it will be found useful to give them a good mulching of well-rotted manure and also frequent and liberal waterings with liquid manure.

S. astilboides.—A distinct and graceful Japanese species, resembling *S. Aruncus* but dwarfier and with smaller and looser leaves and leaflets. Flowers in summer in white spicate panicles. The variety *floribunda* is superior to the type and produces finer trusses of blossom.

Culture &c. as above for *S. Aruncus*. A fine plant for the edge of a pond or stream. Although perfectly hardy it is now grown extensively under glass during the earlier months of the year as a pot plant for table and room decoration, for which purpose its graceful habit and freedom of flowering make it very suitable.

S. cæspitosa.—A tufted species 6 in. high, native of the United States, with

small silky entire leaves; lower ones in a rosette, spatulate, the upper ones linear, minute. Flowers in summer, in dense spiked racemes.

Culture &c. as above for *S. Aruncus*.

S. digitata.—A Siberian herbaceous perennial closely related to the N. American *S. lobata*, from which, however, it differs in having the terminal leaf-lobe more rounded, and the other segments more numerous and narrower, and more or less hairy beneath, especially along the nerves. The flowers are pink or almost white.

Culture &c. as above for *S. Aruncus*.

S. Filipendula (*Dropwort*).—A native of the British Islands, 2-3 ft. high, with smooth, interruptedly pinnate leaves, 4-10 in. long, and deeply cut, serrate leaflets. Flowers in June and July, white or rosy outside, $\frac{3}{4}$ in. across, in loose, paniced cymes. There is a good double-flowered variety called *flore pleno* which is very pretty. Its flowers have been likened to snowflakes, and are very useful for bouquets and other floral decorations.

Culture &c. as above for *S. Aruncus*. The double-flowered variety is best increased by division only.

S. kantschatica.—A native of Kamtschatka 6-9 ft. high, with palmately lobed leaves about 6 in. wide and 4 in. long, having channelled and coarsely hairy stalks, furnished with 2 leafy stipules at the base and a number of irregular leaflets along the whole length. The white, sweetly scented flowers are borne in corymbose heads. This species is also known as *S. gigantea* in some places.

Culture &c. as above for *Spiræa Aruncus*. Near the banks of lakes, ponds, or streams this fine ornamental species attains its greatest height. It is perfectly hardy even in frozen water. The hardy flower border is scarcely a suitable place for it.

S. lobata (*Queen of the Prairie*).—This is a smooth herbaceous perennial 2-8 ft. high, native of North America. Leaves interruptedly pinnate; end leaflet very large, 7-9-parted, lobes incised and toothed, stipules kidney-shaped. Flowers in June, deep rosy-carmine in large terminal cymes. The variety *albicans* has pale rose-coloured flowers.

Culture &c. as above for *S. Aruncus*. This species prefers a somewhat shaded situation.

S. palmata.—A strikingly handsome herbaceous perennial 1-2 ft. high, native of Japan, with crimson stems, and palmately 5-7-lobed leaves; lobes oblong-pointed, sharply serrated. Flowers from June to August, brilliant crimson, in large corymbose panicles. The variety *alba* has white flowers and lighter green leaves; *elegans* is said to be a hybrid between *S. palmata* and *Astilbe japonica* on the one hand, or merely a variety of *S. Ulmaria* on the other. It has white flowers with red anthers, and pinnatisect leaves. The variety *purpurascens* has purple-tinted foliage.

Grown near the edge of ponds or streams, or in moist loamy soil, *S. palmata* makes a noble plant. It may be utilised for the decoration of the greenhouse and conservatory, as well-established plants of it grown in pots will force into early blossom almost as easily as *Spiræa astilboides* and *Astilbe japonica*.

Culture &c. as above for *S. Aruncus*.

S. pectinata.—A N. American herbaceous perennial 6-12 in. high, with tufted creeping stems. Leaves 2 or 3 times cleft with linear acute lobes. Flowers in summer, whitish, in woolly racemes.

Culture &c. as above for *S. Aruncus*.

S. Ulmaria (*Queen of the Meadows*). A pretty native perennial 2-4 ft. high, with furrowed stems, and interruptedly pinnate leaves, white and downy beneath; lower ones 1-2 ft. long, terminal leaflets 1-3 in. long, acutely lobed. Flowers from June to August, white, in much-branched clusters 2-6 in. across. There is a variety called *phyllantha* in which the sepals are transformed into whorled, lance-shaped, sharply serrated leaves; petals and stamens absent, or more or less deformed. There is also a form in which the leaves are beautifully variegated with green, white, and yellow (*aureo-variegata*), besides one (*flore pleno*) having double flowers.

Culture and Propagation.—This species thrives on the edges of streams or ponds or in moist situations in the border or rock garden. It may be increased by seeds or division in the same way as *S. Aruncus*.

S. vacciniifolia (*S. laxiflora*; *S. rhamnifolia*).—A somewhat weak-growing Himalayan perennial 1-2 ft. high, with smooth, ovate, crenate leaves on long

stalks, glaucous beneath. Flowers in July and August, white, in large, loose, shaggy panicles.

Culture &c. as above for *S. Aruncus*. This species requires warm sheltered positions.

S. venusta.—The origin of the true species is unknown. It grows 4-5 ft. high, and has the lower leaves palmately pinnatifid, the upper ones palmatifid with oblong lance-shaped coarsely serrate segments, downy beneath on the ribs. It has rosy flowers in June, and although near *S. lobata* is considered to be a distinct species.

Culture &c. as above for *S. Aruncus*.

S. vestita.—A Himalayan perennial 1-2 ft. high, with somewhat hoary pinnatisect leaves; terminal leaflet 2-6 in. across, palmately 3-5-lobed and toothed. Flowers in June, white, $\frac{1}{4}$ in. across, in much-branched oblong cymes.

Culture &c. as above for *S. Aruncus*. This species requires warm sheltered positions.

SHRUBBY SPIRÆAS

The shrubby Spiræas are increased by cuttings of the young wood inserted in sandy soil, and kept close and shaded until roots begin to form. The lower branches may also be layered in autumn. A large number of shrubby Spiræas ripen seeds in the British Islands, and such may also be increased by their means. The seed should be sown when ripe in cold frames, and the seedlings pricked out the following spring into light rich soil in a warm, but not too sunny, situation.

The shrubby Spiræas are effective in masses on grass or in the shrubbery where they have plenty of room.

S. alpina.—A Siberian species 4-6 ft. high. Leaves oblong lance-shaped, sessile, serrulate, smooth. Flowers in June and July, white in terminal corymb.

Culture &c. as above.

S. arguta (*S. multiflora alba*).—A lovely early-flowering shrub 3-4 ft. high. It is a garden hybrid, one of the parents being the beautiful Japanese *S. Thunbergi*, the other a hybrid called *multiflora*. The plant has a graceful habit, and during May its wiry arching shoots are wreathed with clusters of pure white blossoms, almost before the smooth narrow leaves 1-1 $\frac{1}{2}$ in. long are fully developed.

Culture &c. as above. This beautiful plant should find a place in every good collection of flowering shrubs. It is perfectly hardy in most parts of the kingdom, and may be easily increased by means of layers or cuttings of the young or half-ripened shoots. Plants in pots may be gently forced into early blossom in greenhouses in spring.

S. bella.—A Himalayan species 2-3 ft. high, with smooth, rusty-coloured stems, and smooth, ovate, serrate leaves, glaucous beneath. Flowers in July and August, beautiful red, in spreading terminal corymbs. There is a white-flowered variety.

Culture &c. as above, p. 365.

S. betulifolia (*S. corymbosa*).—An almost smooth shrub 1-2 ft. high, native N.E. Asia and N. America. Leaves simple oval or ovate, toothed towards apex. Flowers in June, creamy-white, in large flat compound corymbs.

Culture &c. as above.

S. Blumei.—A native of Japan 3-6 ft. high, with obovate, blunt leaves, deeply toothed at the apex. Flowers white, in terminal cymes.

Culture &c. as above, p. 365.

S. bracteata (*S. media rotundifolia*). A beautiful Japanese shrub 5-6 ft. high, very free in growth, having roundish leaves with 3 more or less blunt teeth at the apex. It produces an abundance of pure white sweet-scented flowers during the early summer months, in rounded clusters at the ends of the shoots. The upper leaves are much smaller and assume the form of bracts beneath the flower heads.

Culture &c. as above. This very fine plant looks well in bold masses and flourishes in good and fairly moist garden soil. It may be forced gently in greenhouses.

S. bullata (*S. crispifolia*).—A dwarf Japanese shrub 1-1½ ft. high, with erect, wiry branches, densely covered with a rusty down. Leaves nearly sessile, ½ in. long, ovate oblong, crenate, leathery, smooth, dark green and wrinkled above. Flowers in summer, deep pink or ruby, in dense terminal corymbs.

Culture &c. as above. An excellent shrub for the rock garden. It is quite hardy in the north.

S. cana.—A native of Central Europe, 1-2 ft. high. Leaves ovate, ½-1½ in. long,

acute, entire or slightly toothed, hoary-haired. Flowers in summer, white, in racemose corymbs.

Culture &c. as above, p. 365.

S. canescens.—An erect, hairy shrub, 4-6 ft. high, native of the Himalayas. Leaves oval or obovate, blunt, entire. Flowers in summer, pale pink or white, in crowded tomentose corymbs. In the 'Kew Handlist' as many as 24 different names are recorded for this species.

Culture &c. as above, p. 365.

S. cantoniensis (*S. reevesiana*).—A smooth evergreen Japanese shrub, 3-4 ft. high, with small, simple, lance-shaped leaves, 3-lobed and deeply toothed. Flowers in early summer, white, in showy terminal umbels. There is a beautiful double-flowered variety.

Culture &c. as above, p. 365.

S. chamædrifolia (*S. ceanothifolia*). A species 1-2 ft. high, distributed from S.E. Europe to Japan. Leaves ovate, deeply serrate at the apex, downy. Flowers in summer, white, in half-round corymbs. The variety *flexuosa* has elliptic lance-shaped, unequally serrated leaves, and white flowers generally smaller than in the type. The variety *ulmifolia* is a handsome shrub, 3-5 ft. high, with Elm-like leaves, and white flowers in half-round terminal corymbs.

Culture &c. as above, p. 365.

S. decumbens.—A dwarf, trailing shrub 6-9 in. high, fit for rocks and banks, native of the Tyrol. Leaves roundish oval, crenately toothed. Flowers in summer, white, in terminal corymbs.

Culture &c. as above, p. 365.

S. discolor (*S. ariæfolia*).—*Spray Bush.*—A beautiful flowering shrub 8-10 ft. high, native of N.W. America. Leaves rigid, wedge-shaped at the base, dark green above, silvery beneath. Flowers in summer, dull white, in graceful, nodding panicles. This species is seen to the best advantage as an isolated specimen on grass. The variety *dumosa* (also known as *S. Boursieri*) differs from *discolor* in being dwarfer in growth, and with less branched panicles.

Culture &c. as above, p. 365.

S. Douglasi.—A beautiful shrub 3 ft. high, native of N.W. America. Leaves simple, oblong lance-shaped, blunt, serrulate at the apex, downy, white beneath. Flowers in August, rosy, in a dense

terminal cluster 6-9 in. long. This species is sometimes known as *S. Menziesi*.

Culture &c. as above, p. 365.

S. expansa (*S. kumaonensis*).—A vigorous-growing compact shrub 4-5 ft. high, native of the Himalayas, and having rather large lance-shaped leaves, sharply and coarsely toothed near the apex, dull yellowish-green above, and blue-green beneath. The rather small pale red or pink flowers appear in August and September, and are borne in large branching panicles.

Culture &c. as above, p. 365.

S. fissa.—A vigorous Mexican shrub about 8 ft. high, with angular downy branches, small leaves, wedge-shaped at the base, with the side lobes split into a pair of unequal sharp teeth. Flowers in May and June, whitish, in loose terminal panicles.

Culture &c. as above. This can be grown with safety only in the mildest parts of the country.

S. gracilis.—A hairy-branched species 2 ft. high, native of Nepal. Leaves obtuse or roundish elliptic, smooth, glaucous beneath, serrated at the apex. Flowers in July and August, white, in loose, rounded corymbs.

Culture &c. as above, p. 365.

S. hypericifolia (*S. flagellata*).—An Asiatic shrub 4-6 ft. high. Leaves obovate-oblong, 3-4-nerved, entire or toothed, smooth or slightly downy. Flowers in summer, white, in corymbs or sessile umbels. The variety *acuta* (*S. acutifolia*) has spatulate, acute, entire or rarely 3-5-toothed, rather smooth leaves and flowers in sessile corymbs; *Besseriana* has mostly entire leaves and flowers in rather loose corymbs; *crenata* has obovate crenate leaves; *thaliectroides* from Mongolia has smooth glaucous obovate entire leaves, those on the sterile shoots being crenate-obovate or somewhat deltoid.

Culture &c. as above, p. 365.

S. japonica (*S. callosa*; *S. Fortunei*). A very beautiful Chinese and Japanese shrub 3-4 ft. high, with purplish stems and lance-shaped acute, serrated leaves. Flowers in June and July, light and dark rosy-red, in flat terminal corymbs.

There are several fine forms of this, including *alba*, a compact pretty bush about 1 ft. high, with white flowers; *Bumalda*, also dwarf and compact, 2 ft.

high, with deep rose-pink flowers; and its sub-variety *Anthony Waterer* still more brilliant in colour, and very near *rubra*, a handsome form with brilliant purple-red flowers; *splendens* (or *hydrangeaefolia*) has peach-coloured flowers; and *superba* has deep rosy-red ones; *ruberrima* is a hybrid between the variety *Bumalda* and *bullata*. It is dwarfer in habit than *Bumalda* and has also larger and deeper coloured flowers.

Culture &c. as above. The plant grown in pots and sold in large quantities in spring as *Spiræa japonica* belongs to the Saxifrage order, and its proper name is *Astilbe japonica* (see p. 414).

S. lævigata (*S. altaica*).—A Siberian shrub 2-3 ft. high, with smooth, glaucous, entire, oblong lance-shaped leaves. Flowers in June, white, tinged with rose, dioecious, male flowers in larger and looser panicles than the female ones.

Culture &c. as above.

S. lindleyana.—A beautiful Himalayan shrub 4-12 ft. high, with large unequally pinnate leaves composed of 11-21 ovate lance-shaped, coarsely toothed leaflets, glaucous beneath. Flowers in July and August, white, in large plume-like clusters.

Culture &c. as above. In warm chalky soils, and sheltered from north and east winds, this species displays itself to great advantage. But it is near water, and in spots where it has plenty of space, that the greatest development takes place. Seeds are freely produced in favourable seasons, and often sow themselves.

S. media (*S. confusa*; *S. oblongifolia*).—A beautiful shrub 2-4 ft. high, native of N. Asia. Leaves elliptic lance-shaped acute, more or less serrate, hairy beneath. Flowers in June and July, white, in corymbs.

Culture &c. as above, p. 365.

S. Millefolium (*Chamæbatariaria millefolium*).—A dwarf evergreen Californian shrub with much cut leaves like those of the Milfoil (*Achillea*), smooth above, with stellate woolly hairs beneath. Flowers in summer, whitish, in terminal racemes.

Culture &c. as above.

S. nobleana.—This species comes from California, and is closely related to but not quite so hardy as *Douglasi*. It grows 3-4 ft. high and has elliptic or oblong, blunt or acute, more or less toothed

leaves, downy or nearly smooth beneath. Flowers in looser clusters, purple-red, and earlier than *Douglasi*, usually in July and August.

Culture &c. as above, p. 365.

S. prunifolia.—A beautiful Chinese and Japanese shrub 4–5 ft. high, with small, smooth, elliptic oval leaves, connate at the base, and irregularly toothed toward the apex. Flowers in March, pure white, in clusters along the whole length of the branches. The double-flowered variety, *flore pleno*, is a more ornamental plant than the type.

Culture &c. as above. The foliage of this species assumes beautiful scarlet tints in autumn, and is very ornamental.

S. pubescens (*S. chinensis*).—A Mongolian shrub, 2 ft. high, with ovate oblong, acute leaves $1\frac{1}{2}$ in. long, much wrinkled, deeply serrated, somewhat 3-lobed, downy beneath. Flowers in March, pure white, small, slightly fragrant, in rounded heads.

Culture &c. as above, p. 365

S. salicifolia.—A native of Europe, N. Asia and N. America, but now naturalised in parts of the British Islands. It grows 3–5 ft. high, with leaves 2–3 in. long, oblong lance-shaped, serrate. Flowers in July and August, rosy-pink, in dense, somewhat cylindrical cymes. There are several forms, the peculiarities of which are indicated by their names, such as *alpestris*, *carnea*, *grandiflora*, *latifolia*, or *paniculata* &c. There is also a white-flowered variety.

Culture &c. as above, p. 365.

S. sorbifolia.—A pretty Asiatic shrub 3–6 ft. high, with pinnate leaves and lance-shaped, sharply serrated leaflets. Flowers in July and August, white, sweet-scented, in clustered panicles.

Culture &c. as above, p. 365.

S. Thunbergi.—A beautiful Japanese shrub 1–3 ft. high, with smooth, linear lance-shaped, sharply serrated leaves, changing to brilliant crimson in autumn. Flowers in April, white, in great profusion.

Culture &c. as above, p. 365.

S. tomentosa.—A N. American shrub about 3 ft. high, with rusty tomentose stems, and ovate or oblong serrate leaves, woolly beneath. Flowers in July, rosy or rarely white, in dense panicles.

Culture &c. as above, p. 365.

S. trilobata.—This is a handsome shrub 1–2 ft. high, native of the Altaian Mountains. Leaves roundish, lobed, crenated, smooth. Flowers in May, pure white, in numerous compact corymbs.

Culture &c. as above, p. 365.

S. Van Houttei.—A beautiful bush 5–8 ft. high, said to be a cross between *S. media* and *S. trilobata*. In late spring it produces masses of pure white bloom almost hiding the deep green foliage. After flowering the shoots that have borne blossoms should be thinned out, and new shoots will break away and produce an abundance of bloom the following season. This *Spiræa* is now grown rather extensively in pots and gently forced into early blossom in greenhouses.

Culture &c. as above, p. 365.

NEILLIA (NINE BARK).—A genus of 4 or 5 species of branching shrubs, with simple or variously lobed and toothed leaves, and large deciduous stipules. Flowers in racemes or panicles, hermaphrodite. Calyx more or less bell-shaped, 5-lobed. Petals 5, inserted at the mouth of the calyx, shortly clawed. Stamens 10 or more, inserted with the petals. Carpels 1–5, sessile or shortly stalked, free or connate.

Culture and Propagation.—These plants thrive in rich loam, but do well in ordinary soil, and are suitable for shrubberies, borders, or grassland. They may be increased by cuttings of almost ripe wood, inserted in sandy soil under a glass. Seeds are also ripened freely in ordinary good seasons and may be sown in cold frames as soon as ripe. In spring, the seedlings may be transplanted to light rich soil, in warm and sheltered spots.

N. amurensis (*Spiræa amurensis*).—A native of Amur 4–7 ft. high, with somewhat cordate-roundish 3–5-lobed leaves; lobes acute, sharply serrate, white and downy beneath. Flowers in summer, white; filaments of stamens reddish.

Culture &c. as above.

N. opulifolia (*Spiræa opulifolia*).—A beautiful N. American shrub 5 ft. high, with roundish somewhat palmately 3-lobed and heart-shaped leaves. Flowers in June, white, in umbellate corymbs, succeeded by purplish fruits. The variety *lutea* has beautiful yellow-tinted foliage, looking well in the distance. The variety

mollis (formerly known as *Spiræa capitata*) is a form with downy leaves.

Culture &c. as above.

N. rubiflora and **N. thyrsoflora**, natives of Nepal, are not yet well known, nor are they quite hardy in northern parts of this country. The last-named species is a *Spiræa*-like bush about 2 ft. high with bright purple-red stems, and lobed and serrate leaves which assume beautiful purple tints in autumn.

Culture &c. as above.

N. Torreyi (or *Spiræa monogyna*) resembles *N. opulifolia*, but has a more compact habit, and grows only 2-3 ft. high.

Culture &c. as above.

STEPHANANDRA.—A genus with only 2 or 3 species of shrubs, with alternate leaves and hermaphrodite flowers. Calyx lobes and petals 5. Stamens 10.

Culture and Propagation.—This is practically the same as for the Shrubby *Spiræas*. The plants like a rich loamy soil thoroughly well-drained and rather moist than dry on the whole. The addition of a dressing of manure every autumn or winter is very beneficial. They may be increased by dividing the roots in early autumn, or in mild weather in spring. Cuttings of the half-ripened shoots will also root about August in sandy soil under a handlight, and the plants thus obtained may be transferred to the open air the following spring.

S. flexuosa (*Spiræa incisa*).—A deciduous Japanese shrub, with alternate, stalked, incised or pinnatifid leaves, 1½-3 in. long, somewhat triangular in outline, and downy beneath. Stipules leafy, persistent. Flowers in July, white, small, in corymbose panicles or racemes.

Culture &c. as above. When well-grown this is a graceful bush 3-8 ft. high, with long arching shoots and prettily cut foliage. It is best grown in masses by itself or even as single specimens on the grass. It sends out suckers freely from the roots, and may be also increased by this means.

S. Tanakæ.—A Japanese shrub somewhat coarser growing and more fleshy than *S. flexuosa*, and with larger leaves 4-5 in. long, sharply toothed, but not deeply lobed. Flowers small and greenish, in loose panicles, not very attractive.

Culture &c. as above.

EXOCHORDA (PEARL BUSH).—A genus with only one or two species of shrubs closely related to the *Spiræas* in character.

E. grandiflora (*Spiræa grandiflora*).—A handsome Chinese shrub, 6 ft. high, with stalked, lance-shaped oblong entire or serrulate leaves and no stipules. Flowers in May, polygamous diceious, white, large, in axillary racemes. Calyx bell-shaped, 4-5-lobed, rounded. Petals 4-5, large, or rounded, shortly clawed. Stamens 15, short, inserted at the mouth of the calyx. Carpels 5, immersed in the calyx tube but free from it; when ripe, hoary, compressed, ribbed.

E. Alberti is a recently introduced species from Persia, scarcely yet known, although grown at Kew. It is quite hardy and a vigorous grower, and reaches a height of 10-12 ft., very much resembling *E. grandiflora* in appearance. The leaves however are larger and of a brighter green, and the scentless flowers are of a purer white but not quite so large. As stated above, there are 15 stamens in the flowers of *E. grandiflora*, but in *E. Alberti* there are 25, arranged in 5 bundles.

Culture and Propagation.—The Pearl Bush likes a warm rich loam and a somewhat sheltered position. It may be increased by seeds, layers, cuttings of the half-ripened branches, or suckers from the roots. It is a graceful plant for small groups on the grass, and when it bears its white blossoms, each about 1½ in. across, it reminds one of a small single-flowered Rose.

GILLENIA.—A genus with 2 species of erect hairy perennials, with almost sessile 3-foliolate leaves and axillary or terminal hermaphrodite flowers on long stalks. Calyx tube cylindrical, 10-nerved, with 5 erect teeth. Petals 5, linear lance-shaped. Stamens 10-20. Carpels 5, distinct or united. Follicles 5, leathery.

Culture and Propagation.—Gillénias are natives of N. America and thrive in moist peat and loam in partial shade, and may be grown under taller plants in the shrubbery. They may be increased by dividing the roots in spring every three or four years when the plants have made good clumps. Seeds may also be sown as soon as ripe in cold frames, and the seedlings transplanted in mild weather the following spring.

G. stipulacea.—A perennial 1-2 ft. high, with lanceolate deeply cut leaves, and white flowers in June.

Culture &c. as above, p. 369.

G. trifoliata (*Spiraea trifoliata*).—A Spiræa-like plant about 1½-2 ft. high, with 3-parted leaves, and linear, entire, pointed stipules. Flowers in June and July, red or white.

Culture &c. as above, p. 369.

KERRIA (JEW'S MALLOW).—A genus with one or two species of slender-stemmed deciduous shrubs with stalked, simple, long pointed, largely and unequally toothed leaves, linear awl-shaped stipules, and large yellow, solitary, stalked flowers at the ends of the branches. Petals 5, broad oblong or rounded, shortly clawed. Stamens numerous. Carpels 5-8, dry, indehiscent.

K. japonica.—A pretty Japanese shrub 3-4 ft. or more high, with bright green, shining leaves, rather smooth above, paler and slightly hairy beneath. Flowers in spring and early summer, orange-yellow, numerous. The double-flowered variety is best known and is usually seen trained to walls. It looks well, however, grown as a bush, the slender arching stems being covered with yellow blossoms. There is a beautiful variety with leaves variegated with sea-green, pale yellow and white.

Culture and Propagation.—Kerrias thrive in any good soil. They may be increased by layers, division of the roots in early autumn or spring, or by cuttings of the young shoots in sandy soil under a glass. After flowering the old wood may be cut out where necessary and the young shoots exposed to the light and air as much as possible.

RHODOTYPOS (WHITE JEW'S MALLOW).—A genus with one species described below, with the generic characters:—

R. kerrioides.—A charming deciduous Japanese shrub, 5-15 ft. high, with decussately opposite, stalked, ovate, pointed, deeply serrated leaves, silky beneath. Flowers in May, white, hermaphrodite, solitary, on short stalks at the ends of the branches, numerous. Calyx lobes 4, large, leafy, deeply serrated. Petals 4, large, rounded, shortly clawed. Stamens numerous. Carpels 1-4, drupe-like, rown, shining, 1-seeded.

Culture and Propagation.—This species may be grown like the *Kerria*, either as a bush or wall plant. It is increased in the same way by layers, division of the roots in early autumn or early spring, or by cuttings of the young shoots, and likes similar soil. Seeds are also ripened freely in favourable seasons, and if sown in cold frames as soon as ripe, or in gentle heat in spring, will produce young plants which may be pricked out and transferred to the open ground when strong enough.

NEVIUSIA (ALABAMA SNOW WREATH). Another genus with only one species. The following description includes the generic characters:—

N. alabamensis.—A somewhat rare and beautiful United States shrub with alternate, stalked, ovate or oblong, doubly serrate leaves, and small free stipules. Flowers rather large, hermaphrodite, white or yellowish-green, on slender stalks along the length of the branches. Calyx 5-lobed, lobes leafy, serrated. Petals none. Stamens numerous, conspicuous. Carpels 4. Drupes 4, Pea-like.

Culture and Propagation.—At Kew this plant flowers freely in the open air, and it will probably prove hardy in most parts of the country. It thrives in warm loamy soil, and may be treated like *Neillia* or *Rhodotypos*. Propagation may be effected by means of cuttings of the half-ripened shoots in sandy soil under a hand-light, or the lower branches may be layered in autumn and severed from the parent plant the following year when well rooted.

ADENOSTOMA.—A genus with 2 species of rigid, branched shrubs, with Heath-like, linear, leathery, entire leaves, solitary or clustered. Flowers hermaphrodite, racemose or paniculate. Calyx obconic, bell-shaped, 10-ribbed, leathery, 5-lobed. Petals 5, round. Stamens 12 (or 8-15). Fruit a leathery achene.

A. fasciculata.—A Heath-like Californian evergreen bush about 2 ft. high, with the characters above described.

Culture and Propagation.—It thrives in a peat and loamy soil, and may be increased by cuttings of the young shoots in sandy soil under glass. This plant is very rarely seen.

Tribe III. QUILLAJEÆ.—Trees or shrubs with simple, rarely pinnate leathery leaves. Calyx lobes often persistent. Stamens 5–10–20. Carpels free or united. Fruit follicular, or a coccus or capsule.

LINDLEYA.—A genus with one species, the description of which below includes the generic characters.

L. mespiloides.—A beautiful Mexican Medlar-like tree, 20–30 ft. high, with simple crenulate leathery leaves, and small awl-like stipules. Flowers in July, hermaphrodite, white, sweet-scented, axillary or at the tips of the shoots. Calyx persistent, 5-lobed; petals 5, roundish, sessile, large. Stamens 15–20, inserted at the mouth of the calyx. Carpels 5. Capsule woody, oblong, 5-angled or furrowed.

Culture and Propagation.—In the southern and milder parts of the country this evergreen tree will doubtless prove hardy. It likes well-drained loamy soil with a chalky bottom. It may be increased by cuttings under glass, or by grafting on the Common Hawthorn. It is a plant very rarely seen.

EUCRYPHIA.—A genus with 3 species of smooth or woolly resinous trees, with opposite, leathery, evergreen, simple or pinnate, entire, toothed or crenate leaves. Sepals 4, oblong, concave, cohering at the tips. Petals 4, large, somewhat hypogynous, broadly obovate rounded, straight or oblique. Stamens very numerous. Capsule leathery or woody, 5–12-furrowed.

Culture and Propagation.—The

Tribe IV. RUBEÆ.—Shrubs or undershrubs, often prickly; leaves often compound. Calyx lobes persistent. Stamens and carpels numerous. Drupes many, not enclosed by the calyx tube.

RUBUS (BRAMBLE).—A genus containing about 100 distinct species of creeping herbs, or climbing prickly shrubs, with alternate, simple, lobed, 3–5-foliolate or oddly pinnate leaves, with stipules adnate to the stalks. Calyx lobes 5, persistent. Petals 5. Stamens and carpels usually numerous. Fruit consisting of fleshy drupes aggregated on a conical receptacle (well seen in the Common Raspberry).

Culture and Propagation.—From a flower garden point of view, only a few of the best Brambles are worthy of cultivation, and even they are chiefly useful for clothing unsightly banks or walls or

species described below like a warm loamy or peaty soil and somewhat sheltered positions, especially in northern parts, in beds by themselves on grass or in borders. They may be increased by ripened cuttings inserted in sand under glass and protected during the winter months.

E. Billardieri Milligani is a beautiful white-flowered evergreen shrub, recently introduced to cultivation from Tasmania. It is somewhat tender, and will scarcely succeed in the open air far beyond the Midlands.

Culture &c. as above.

E. cordifolia.—A Chilean tree, 20 ft. high, with heart-shaped oblong, crenated, downy leaves. Flowers large, white, axillary, solitary, stalked.

Culture &c. as above.

E. pinnatifolia.—A distinct and beautiful shrub 2–3 ft. high, also native of Chili, with pinnate leaves composed of ovate serrate or toothed leaflets. Flowers white, large, about 3 in. across, usually in pairs near the ends of the shoots, and having a cluster of numerous stamens in the centre. They are borne in July and August and give the plant an extremely handsome appearance.

Culture &c. as above.

rougher parts where little else will grow, or where choicer plants would be out of place. They have the great advantage of flowering freely and growing in the poorest of garden soils, although of course the better the soil, the more vigorous will the plant be. They are easily increased by suckers, division, layers, or seeds. The latter may be sown as soon as ripe either in cold frames for the more tender kinds, or in the open border for the hardier ones. The seedlings may be transplanted in spring during mild weather. It is, however, much quicker to divide the roots, or replant suckers, or to detach the rooted layers.

Besides the kinds described below there are many others to be found in botanical collections such as Kew, but they are scarcely worth mention here from a flower garden point of view.

The Raspberry (*R. Idæus*) is treated separately at p. 1085.

R. arcticus.—A small non-prickly species about 6 in. high, native of the Arctic regions. Leaves 3-foliolate with rhomboid-ovate coarsely toothed leaflets. Flowers in June, rose-pink, useful for the rock garden.

Culture &c. as above.

R. australis.—A distinct-looking New Zealand climber with prickly stems and practically no leaves as popularly understood. There is, however, great variation in regard to these, as some forms have large deep shining green leaves, composed of 3-5 leaflets with coarsely toothed margins. Flowers in early summer, pink or white, fragrant, about $\frac{1}{2}$ in. across. Fruit yellow, juicy. This is not quite hardy in all parts, and should be trained up a south wall.

Culture &c. as above.

R. biflorus.—A tall prickly Himalayan species, with whitish stems, leaflets 3-5, ovate, doubly toothed, downy or hairy above, white and woolly beneath. Flowers in May, white, $\frac{1}{2}$ - $\frac{3}{4}$ in. across. Fruit golden-yellow.

Culture &c. as above. Even in a leafless condition in winter, this species cannot fail to attract attention, as its cane-like stems stand out clearly on the landscape, being so white that the uninitiated are apt to imagine them to be white-washed.

R. Chamæmoris (*Cloudberry*).—A non-prickly British species 4-8 in. high. Leaves 5-7-lobed, crenate, wrinkled. Flowers in summer, white, 1 in. across; sepals hairy. Fruit orange-yellow, $\frac{1}{2}$ in. in diameter.

Culture &c. as above.

R. deliciosus.—A beautiful North American climber, with roundish, kidney-shaped, wrinkled leaves slightly 3-5-lobed, finely serrated. Flowers in May, purple, about 2 in. across, produced in great abundance. Fruit large, delicious flavour.

Culture &c. as above. This may be grown as a shrub by cutting back the shoots. It is very ornamental when in bloom and may be used in clumps by

itself or in the shrubbery in an open situation.

R. fruticosus (*Blackberry*; *Bramble*). A well-known prickly denizen of British and Irish hedges, copses, and waste places, with beautiful white or pink flowers, and large black or reddish-purple fruits, excellent either in a raw, cooked, or preserved state. The double white and double pink varieties with flowers like rosettes are very pretty and well worth having in any Bramble collection. There is also a form with variegated leaves. Some of the American varieties, like *Lawtons*, *Kittatinny*, *Mammoth*, do not thrive in this country, but the *Parsley-leaved Blackberry* grows very well.

Culture &c. as above.

R. japonicus tricolor.—A handsome Japanese trailer with slender stems, and leaves with 3-lobed toothed or serrate margins, and remarkable for their pretty white and green marbling, mixed with soft rosy-pink. The young leaves look particularly handsome.

Culture &c. as above. This is a newly introduced Bramble and will no doubt prove quite hardy, at least in the mild southern and western parts of the kingdom.

R. laciniatus.—A distinct, prickly, straggling species with leaves composed of 3-5, dissected and sharply serrated leaflets somewhat downy beneath. Flowers from June to September, white or rosy; petals 3-lobed at the apex.

Culture &c. as above.

R. lasiostylus.—A Chinese species 4-5 ft. high, densely set with prickles, and covered with a bluish-white bloom. Flowers in summer, small, reddish-purple.

Culture &c. as above.

R. leucodermis.—A native of N.W. America somewhat like *R. biflorus*, but it is not such a strong grower, nor are the prickly stems so white, but more distinctly bluish. Flowers white. Fruit yellowish-red, with a good flavour.

Culture &c. as above.

R. neglectus.—A N. American plant supposed to be a hybrid between *R. occidentalis* and *R. strigosus*. It has stout prickly stems about 8 ft. high covered with a white or bluish-white bloom. Flowers white. Fruit dark red.

Culture &c. as above.

R. nutkanus.—A native of Nootka Sound, with hairy, flexuous stems 1–10 ft. long. Leaves 5-lobed, coarsely and unequally toothed. Flowers in August, white, large, followed by red fruits.

Culture and Propagation.—This species thrives near water or in moist soil, and may be increased in the ways mentioned above. It ripens seeds freely in the British Islands.

R. occidentalis (*Thimbleberry* or *Black Raspberry*).—A native of the Eastern United States and Canada, with dull bluish-white arching stems 5–6 ft. high. Flowers white, succeeded by purple-black fruits.

Culture &c. as above.

R. odoratus (*Purple Virginian Raspberry*).—A non-prickly N. American species 3–5 ft. high, with 3–5-lobed leaves, minutely toothed. Flowers from June to August, purple-rose, 2 in. across, many on a stalk.

Culture &c. as above.

R. phœnicolasius (*Japanese Wineberry*).—A tall-growing Japanese species covered with stiff glandular purple-red hairs. Leaves 5–7 in. long, 3-foliolate or simple; leaflets crenate-serrate, downy white beneath. Flowers in June, pale

pink, succeeded by scarlet fruits $\frac{3}{4}$ in. long, to which birds are very partial.

Culture &c. as above.

R. rosæfolius.—A Himalayan species, fit only for the mildest parts of the country. Leaflets 5–7, ovate lance-shaped, pointed, deeply serrated. Flowers in August, white, about 1 in. across. Fruit orange-red. The double variety *coronarius* is a great improvement on the type, but is likewise tender. It makes pretty specimens if grown in small pots in the greenhouse during the winter months. According to the 'Kew Handlist' this variety is now known as *R. thyrsoides fl. pl.*, but the name *rosæfolius* is very descriptive of the foliage and is retained here as it is much better known.

R. spectabilis (*Salmon Berry*).—A dense, erect-growing, North American bramble 6–10 ft. high. Leaves 3-foliolate; leaflets ovate pointed, deeply cut, and serrate. Flowers in May, bright red or purple, large. Fruit red, twice the size of the common Raspberry, but inferior in flavour.

Culture &c. as above.

R. strigosus.—A native of N.E. America with glaucous stems covered with bristles rather than prickles. Flowers white. Fruit red.

Culture &c. as above.

Tribe V. POTENTILLÆ.—Herbs or shrubs. Calyx persistent bracteolate. Stamens and carpels usually numerous.

PURSHIA.—A genus containing only the following species, the description of which includes the generic characters:—

P. tridentata.—A pretty hardy evergreen shrub 2–3 ft. high, native of N.W. America. The branches are furnished with clusters of small alternate, somewhat wedge-shaped leaves cut into 3 linear lobes, with recurved margins and a whitish downy under surface. The short-stalked yellow flowers appear in summer. The persistent 5-lobed calyx is elongated tubular or funnel-shaped, and the corolla consists of 5 obovate clawed petals surrounding about 25 stamens in the centre.

Culture and Propagation.—This little-known shrub flourishes in ordinary good and well-drained garden soil of a somewhat sandy nature. It appears to be perfectly hardy, and may be increased by inserting cuttings of the young or half-

ripened shoots in sandy soil under a bell-glass during the summer months.

CHAMÆBATIA.—This genus is also represented only by the one species described here:—

C. foliolosa.—A pretty evergreen shrub 2–3 ft. high, native of California. The young shoots are clothed with a glandular down and broadly ovate rather clammy leaves about 2 in. long, thrice pinnately cut or divided. The white flowers, about $\frac{3}{4}$ in. across, appear in summer in cymose clusters at the ends of the shoots. Calyx persistent with a bell-shaped or hemispherical tube, and 5 lobes. Petals 5, obovate. Stamens numerous in many series, inserted on the throat of the calyx.

Culture and Propagation.—This is a somewhat tender shrub and is scarcely hardy enough to be grown in the open air

except in the milder parts of the kingdom. It flourishes in good well-drained garden soil, or rich sandy loam, with a little peat or leaf mould added, and may be increased by cuttings of the half-ripened shoots inserted in sandy soil under a handlight or in a cold frame.

DRYAS (MOUNTAIN AVENS).—A genus with 2 species of pretty dwarf tufted, shrubby plants, with simple, stalked, oblong, entire, crenate, or somewhat pinnatifid leaves, shining above, white beneath. Stipules adnate to the leaf stalk. Flowers on slender, erect scapes, solitary. Calyx tube short, glandular hairy. 8-9-lobed. Petals 8-9, broadly obovate. Stamens and carpels numerous. Achenes with slender feathery tails.

Culture and Propagation.—These plants thrive in moist peaty soil, and may be increased by cuttings inserted in sandy soil in spring under glass; by division of the roots in early autumn, or better still in spring when growth is commencing; or from seed sown in spring in the open border in mild weather, or early in autumn as soon as ripe in cold frames. The seedlings are best wintered in cold frames the first season so as to enable them to become strong and sturdy before transferring to the moist parts of the rockery or edges of borders.

D. Drummondii.—A rare N. American evergreen trailer, with elliptic deeply crenate leaves, white beneath. Flowers in June, golden-yellow, about 1 in. across.

Culture &c. as above.

D. lanata (*D. nivea*).—This is a curious Tyrolese form of *D. octopetala* with much narrower and whiter leaves. The flowers are rather smaller than those of *D. octopetala*, but are more freely produced, and the whole plant is more vigorous.

Culture &c. as above. Growing naturally on the sunny slopes of the southern Tyrol, this plant requires open sunny situations and will flourish in well-drained sandy loam. It may be increased by seeds or division.

D. octopetala (*D. depressa*).—A dwarf tufted British plant with obovate coarsely toothed leaves about 1 in. long, hoary beneath, shining above. Flowers in May and June, white, with conspicuous yellow stamens in the centre. Calyx very

hairy. There is a pretty little form called *minima* useful for the rock garden.

Culture &c. as above.

FALLUGIA.—A genus represented only by the following species:—

F. paradoxa (*Sieversia paradoxa*).—

An erect much-branched shrub 4 ft. or more in height, native of California and Mexico. The alternate stalked leaves are more or less irregularly cut into 3-5 linear blunt lobes with recurved margins and a snowy-white under surface. The large white showy flowers are borne either solitary at the ends of the shoots or in small panicles. The persistent calyx tube is obconical or hemispherical, with 5 ovate 3-toothed or tailed lobes. Petals 5 obovate roundish. Stamens and achenes numerous, the latter ending in feathery tails.

Culture and Propagation.—This is not a well-known plant. It flourishes in ordinary good garden soil, and likes warm sheltered and sunny situations. In the northern and bleaker parts of the kingdom it would probably be unable to stand a hard winter unless well protected with mats. It may be increased by seeds if obtainable, sown as soon as ripe in cold frames, or by means of cuttings of the half-ripened shoots inserted in sandy soil under a handlight in summer.

GEUM (AVENS).—A genus with about 30 species of perennial herbs with tufted pinnate radical leaves, having a very large terminal lobe. Stipules sheathing and adnate to the base of the leaf stalk. Flowers solitary or corymbose. Calyx persistent with 5 bracteoles below the 5 lobes. Petals 5, rounded or obovate. Stamens and carpels many.

Culture and Propagation.—Geums are easily grown in any fairly rich loamy soil. They are excellent border or rock plants, and like plenty of sun above, and moisture at the roots during hot summers. Propagation is mostly easily effected by dividing the roots or clumps in early autumn, or in spring as growth commences, when the plants have made large masses, and would be benefited by the process. Seeds are freely ripened by most of the kinds, and may be sown as soon as ripe either in cold frames or in sheltered spots in the open border, afterwards pricking the seedlings out in spring about 1 ft. apart. Seeds may also be sown in the

open air in spring, and the seedlings transplanted early in autumn.

G. chilense.—A beautiful hairy perennial 1–3 ft. high, native of Chiloe. Leaves pinnate, with crenate-serrated leaflets. Flowers in summer, scarlet, sometimes shaded with bronze. The variety *grandiflorum* has flowers of a dazzling scarlet; *miniaturum* is also a splendid variety with brilliant flowers, while the double or semi-double flowered form is equally handsome and brilliant in colour.

Culture &c. as above. The species and varieties mentioned are among the very finest of the Geums and should find a place in the herbaceous border for the great brilliancy of their flowers. They are all easily increased by dividing the rootstocks early in autumn or in spring. Any specially fine form is best increased in this way, as seedlings have a great tendency to vary from the parent plant.

G. coccineum.—A native of S.E. Europe, 6–12 in. high, rather rare, but often mixed up with the preceding species. Leaves large, lyrate-pinnatifid with 5–7-toothed leaflets. Flowers in summer, scarlet, with roundish obovate petals. *Heldreichi* is a Greek form with deep orange-red flowers. There is also a form with semi-double bright scarlet flowers.

Culture &c. as above.

G. elatum.—A pretty Himalayan species with pinnately cut leaves the segments of which are roundish oblong and irregularly toothed. Flowers in summer, golden-yellow, on long slender stalks.

Culture &c. as above.

G. macrophyllum.—A North American species 9–12 in. high, with leaves ending in a large roundish heart-shaped lobe, and having a few golden-yellow flowers on the stem.

Culture &c. as above.

G. molle.—A native of the Servian and Balkan mountains closely related to *G. pyrenaicum*, from which it differs in having smaller and more softly hairy leaves of a bright green colour, and larger bright yellow blossoms in June.

Culture &c. as above.

G. montanum.—A native of the Alps 6–12 in. high, with softly hairy, incised leaves. Flowers in summer, 1½ in. across, yellow, on stems 9–18 in. high, succeeded by a cluster of feathery tailed

seeds of a reddish-brown colour. There is a large-flowered variety called *grandiflorum*, and a brilliant orange-coloured one called *aurantiacum*.

Culture &c. as above. It likes warm spots in the border or rockery fully exposed to the sun.

G. pyrenaicum.—A hairy Pyrenean perennial about 1½ ft. high. Lower leaflets small, ovate, toothed. Flowers in June, yellow, nodding, 1–4 on a stem.

Culture &c. as above.

G. radiatum.—A handsome perennial, 12–18 in. high, native of the high mountains in Carolina. It has roundish, kidney-shaped leaves with radiating veins, and large bright yellow blossoms resembling those of *G. montanum*.

Culture &c. as above.

G. reptans.—This pretty species is really the rock form of *G. montanum*. It grows in the clefts of rocks and in rocky débris on the higher Alps at an elevation of 6000–7500 ft. and is also native of the Pyrenees and the mountain ranges of Eastern Europe. The plant sends out long thread-like runners, at the tips of which are small buds or shoots which take root. The grey-green velvety leaves are more deeply and finely divided than those of *G. montanum*, and the flowers are larger, about 2 in. across, and of a soft yellow colour, appearing in summer, and afterwards followed by purple hairy seed heads.

Culture &c. as above. It flourishes in moist well-drained gritty, but not calcareous, soils.

G. rheticum.—A native of the Swiss Alps, 6–9 in. high, with hairy lyrate and pinnately cut bright green leaves. The bright yellow flowers, an inch or more across, are usually produced singly on the top of the stem, with 2 or 3 reduced leaves or bracts beneath.

Culture &c. as above.

G. rivale (*Water Avens*).—A British plant 1–3 ft. high, found by the banks of streams &c. Leaves variable, pinnate, with more or less obovate toothed leaflets. Flowers from May to July, 1–1½ in. across, yellow or orange.

Culture &c. as above. May be grown in marshy places in the rockery, or near streams, pools &c.

G. strictum.—A distinct species with a wide geographical distribution, being

found on the Caucasus, in Siberia, and North America. It grows 2-2½ ft. high, and has oval pinnate leaves covered with soft hairs, and produces an abundance of golden-yellow flowers during the summer months.

Culture &c. as above.

G. triflorum (*Sieversia triflora*).—A pretty N. American perennial with interruptedly pinnate leaves 4-6 in. long, with deeply serrated leaflets. Flowers in summer, white, tipped and edged with purple-red, or purplish, on hairy stems 8-12 in. high. Calyx dark purple.

Culture &c. as above. It likes a moist and rather light soil in partially shaded spots in the rockery or border.

WALDSTEINIA.—A genus with 4 species of creeping perennial Strawberry-like herbs. Calyx persistent, 5-lobed, with 5 minute bracteoles. Petals 5, obovate. Stamens many. Achenes dry or fleshy, downy or hairy.

Culture and Propagation.—These plants grow well in ordinary soil and are suitable for the rockery. They may be increased by seeds or division in spring or in early autumn. Seeds may be sown when ripe in cold frames or in the open border in sheltered spots, and the seedlings may be pricked out in mild weather in spring. Seeds may also be sown at the latter period and the seedlings transplanted in mild showery weather in early autumn. The plants, however, are so very easily divided that it is scarcely worth while to go to the trouble of raising them from seed, unless a very large number of plants are required.

W. fragarioides (*Barren Strawberry*). A showy N. American perennial with bright red hairy stems about 6 in. high, with ternate leaves, and obovate irregularly toothed leaflets. Flowers in early summer, bright yellow, about ½ in. across.

Culture &c. as above.

W. geoides.—A dwarf tufted Hungarian perennial 4-6 in. high, with palmately 3-5-lobed and toothed leaves. Flowers in May and June, small, yellow, numerous, usually in terminal pairs.

Culture &c. as above.

W. trifolia.—A native of E. Europe 4-6 in. high. Leaves 3-lobed with shortly stalked hairy leaflets. Flowers in April and May, rich golden-yellow. *W. sibirica*

from Siberia appears to be a form of this species.

Culture &c. as above. This is a charming plant for trailing over rocks, and looks much better grown in this way than as a flat patch in the rockery.

FRAGARIA (STRAWBERRY).—A genus with only a few species of silky or hairy perennial herbs, with runners or stolons. Leaves 1-3-foliolate or pinnate. Flowers polygamous-dioecious. Calyx persistent, 5-lobed, 5-bracteolate. Petals 5, broadly obovate, shortly clawed. Stamens many, persistent. Carpels many, distinct, on a fleshy convex receptacle, which in the case of the Strawberry is eaten as the fruit.

Culture and Propagation.—The Strawberries for the flower garden are easily grown in ordinary soil not too wet or cold, and are easily increased by dividing the rootstocks or the runners. The plants may be utilised for the ornamentation of rockeries, old ruins, walls &c. The Strawberry proper is treated upon at p. 1088.

F. chilensis.—A pretty S. American species about 1 ft. high, with obovate, serrate, wrinkled leaflets, silky beneath. Flowers in April and May, white, on thick silky stalks. Fruit rosy, white-fleshed. The variety *grandiflora* (known as the Pine Strawberry) has glaucous leaves hairy beneath, and somewhat larger flowers than the type.

Culture &c. as above.

F. indica, with golden-yellow flowers, and the various forms of the white-flowered Wild Strawberry (*F. vesca*) are useful in conjunction with the above for the rockery or chinks of old walls.

Culture &c. as above.

POTENTILLA (CINQUEFOIL).—A genus with about 120 species of smooth, hairy or silky tomentose perennial herbs or undershrubs, rarely annuals. Leaves digitately 3-7-foliolate or oddly pinnate, with stipules adnate to the base of the stalk. Flowers in corymbose cymes, rarely axillary and solitary. Calyx persistent, usually 5-lobed, with 5 bracteoles. Petals 5, rarely 4, obovate roundish, or linear spatulate. Stamens, carpels, achenes many.

Culture and Propagation.—Potentillas prefer a sandy soil. Many of them are useful for rockeries, banks &c., and a few of the best make splendid border

plants. They may be increased by dividing the rootstocks or by sowing seeds in spring in the case of the single-flowered kinds. The double-flowered varieties are best increased by division, as they do not usually seed so freely as the single ones, and also because seedlings rarely come with the true characters of the parent plants.

The Double Potentillas are by far more beautiful garden plants than the natural species. Grown in a light deep soil with plenty of sun they make glowing pictures in the flower garden from June to September. Although the flowers are more or less double, and resemble small Roses, they ripen some seeds, and from these new forms may be obtained by those in search of novelties.

These double-flowered forms are the result of crossing the *atrosanguinea* form of *P. argyrophylla* with forms of *P. nepalensis*, and it is remarkable that these Himalayan species have produced such a fine hardy race of ornamental flowers.

The following is a list of the best double Potentillas:—

Califorme, large golden-yellow; *Candidat*, brick-red, suffused gold; *Carnival*, orange-yellow, flaked crimson; *Cendrillon*, red, shaded yellow; *Chinois*, very large rich maroon and yellow; *Chromatella*, clear yellow, effective; *Congo*, dark maroon and yellow; *Don Quixote*, soft yellow, splashed scarlet; *Eldorado*, scarlet-crimson, shaded gold; *Feu Follet*, orange-scarlet, with broad orange margin; *Golconde*, rich crimson, suffused and edged gold; *Jupiter*, vivid crimson, suffused yellow; *Le Vésuve*, vermilion, flushed and blotched golden; *L'Achéron*, brilliant velvety red and yellow; *Madame Rouillard*, rich velvety scarlet, edged golden, very large flowers; *Marron d'Inde*, maroon and yellow; *Melpomene*, bright yellow, shaded orange-scarlet; *Milton*, yellow, heavily blotched bright red; *Orphée*, beautiful self-yellow; *Panorama*, chrome-yellow, striped purple; *Purpurea plena*, rich deep purple-crimson; *Purpurea lutea plena*; *Richesse*, fiery scarlet, splashed gold; *Toussaint l'Ouverture*, rich velvety scarlet, tipped gold; *Van Dyck*, yellow, striped red; *Vase d'Or*, canary-yellow; *Velours Pourpre*, dark velvety purple, large double flowers; *Versicolor*, crimson-scarlet, shaded orange; *Vulcan*, rich deep crimson; *William*

Rollison, glowing scarlet shading to orange-yellow, very showy and handsome.

P. alba.—A dwarf procumbent species 3-6 in. high, native of the Alps, with silvery leaves and large white flowers 1 in. across, from February to August.

Culture &c. as above.

P. alchemilloides.—This is a native of the chalky mountain districts of the Pyrenees, and grows 6-12 in. high, with ascending stems, and leaves composed of 5-7 oblong oval leaflets. The pure white flowers appear in great abundance from June to August.

Culture &c. as above.

P. alpestris.—A somewhat rare British plant 6-12 in. high, with rather hairy leaves, composed of 5 leaflets, and bright yellow flowers 1 in. across, in early summer.

Culture &c. as above. It likes a deep moist soil.

P. ambigua.—A creeping Himalayan species 6 in. high, with masses of leaves forming a green carpet on the ground. Flowers in June, rich yellow, 1 in. across, just overtopping the foliage.

Culture &c. as above.

P. anserina (*Silver Weed*).—A pretty and distinct species, native of the Northern temperate hemisphere, being found growing naturally in moist sandy soil in most parts of Europe, N. Asia, and N. America. It has a creeping rootstock, and interruptedly pinnate leaves composed of many deeply serrate or pinnately divided leaflets, the under surface of which is clothed with soft silky white hairs, which give them a silvery appearance. The solitary yellow flowers $\frac{3}{4}$ -1 in. across are freely produced in July and August.

Culture &c. as above. This species may be used for covering the sides of banks or slopes, or for furnishing waste places.

P. apennina (*P. Bocconi*).—A dwarf tufted species, native of the pastures high up on the Apennines. The leaves are composed of 3 oval leaflets, and the large flowers of a bright yellow colour are borne in summer.

Culture &c. as above. Suitable for the border or rockery in open sunny places. It likes a mixture of peat, loam, and sand.

P. argentea.—A slender-growing species 6–12 in. high, native of the dry mountainous regions of Europe, Asia Minor, Siberia, and N. America. The leaves are composed of 5 obovate leaflets, greyish-green above, silvery-white beneath. The small yellow flowers are borne in a terminal panicle from June to September.

There are several forms of this species, and a hybrid between it and *P. verna* also exists. *P. collina*, a native of Bohemia, is closely related.

Culture &c. as above, p. 376.

P. argyrophylla (*P. insignis*).—A pretty Himalayan species 1½–3 ft. high, with silky, silvery, sharp-toothed leaves. Flowers in summer, yellow, over 1 in. across. The variety *atrosanguinea* has beautiful dark crimson flowers, and there is also a fine double-flowered form of it from which most of the garden forms are derived.

Culture &c. as above, p. 376.

P. aurea.—A very dwarf tufted species scarcely more than 1–2 in. high. It is a native of the European mountain ranges at elevations of 3000 to 6000 ft. The palmate leaves have 5 oblong lobes edged with silky silvery hairs. The large golden-yellow flowers, spotted with orange at the base of each petal, are borne in loose panicles from May to July.

P. baldensis from the Tyrolean Alps is closely related, but may be distinguished by its denser habit, smaller and more numerous yellow flowers, and hairy leaves.

Culture &c. as above. Suitable for the rock garden, or for making a carpet in the flower border, in open sunny situations in sandy soil, with a little peat or leaf-mould added.

P. bifurca.—A Caucasian species in the way of *P. anserina*, having thread-like rooting runners, and pinnate leaves composed of 3–7 pairs of oblong very downy leaflets. The bright yellow flowers are borne on an erect panicle 9–12 in. high from May to July.

Culture &c. as above, p. 376.

P. Calabra.—A native of S. Europe, with very silvery 5-lobed leaves, and lemon-yellow flowers about ¾ in. across, produced in early summer. This is closely related to *P. argentea*, and is practically only a form of it.

Culture &c. as above, p. 376.

P. canescens.—An erect-growing perennial 1–2 ft. high, native of the European mountain ranges. The grey-green leaves are composed of 5–9 leaflets, and are covered with a silvery down on the under surface. The yellow flowers are borne in broad clusters from May to July.

Culture &c. as above, p. 376.

P. caulescens.—A pretty species, native of the Alps, Apennines, Pyrenees &c., with leafy stems 6–9 in. long. The lower leaves are composed of 5 leaflets, the under surface and the margins of which are furnished with silky hairs. The white flowers appear in great profusion from June to August.

Culture &c. as above. A sunny crevice in the rockwork or in stony well-drained soil suits this species best.

P. chrysantha.—A native of the mountains of Central Europe, 1–2 ft. high, with downy leaves composed of 5–7 pairs of oblong toothed leaflets. The light yellow flowers are borne on a large panicle from May to August.

Culture &c. as above, p. 376.

P. cinerea.—A dwarf creeping species, native of the mountains of S. Europe and Asia Minor. The leaves are covered with a whitish down, and are composed of 4–5 thick leathery leaflets. The small bright yellow flowers are produced with great freedom from May to August.

Culture &c. as above, p. 376.

P. clusiana.—A small species 2–3 in. high, native of the chalky rocks of the Tyrol and Carpathian Mountains at an elevation of 3000–6000 ft. The 3–5 oblong leaflets which compose the leaves are covered with silky down, and the white flowers appear in May and June, 2 or 3 together at the top of the leafy stems.

Culture &c. as above, p. 376.

P. congesta (*Horkelia congesta*).—A Californian species 1–2 ft. high, with wedge-shaped oblong leaflets cut at the apex. Flowers in August, white, crowded on the stalks.

Culture &c. as above, p. 376.

P. delphinensis.—A dwarf tufted species 9–18 in. high, with digitate leaves made up of 5–7 lobes, green on both sides. The numerous bright yellow flowers are borne in summer, closely arranged on the panicle.

Culture &c. as above, p. 376.

P. Detommasi.—This is a large and handsome plant from the Macedonian mountains, closely related to *P. argentea*, from which it may be distinguished by its more ornamental foliage and its larger and more brilliant flowers.

Culture &c. as above, p. 376.

P. Fenzli.—A pretty little species 6-9 in. high, native of the mountains of Macedonia and Asia Minor. It has finely divided silky leaves clothed with a silvery down, and the small yellow blossoms are produced in close-set panicles in summer.

Culture &c. as above, p. 376.

P. frigida.—This handsome little species is a native of the Alps, Pyrenees, and Rocky Mountains, and has somewhat trailing or ascending stems clothed with hairy leaves which are composed of 3 olive-green leaflets. The small golden-yellow flowers are almost stalkless, and appear either solitary or in pairs at the tips of the shoots from June to September.

Culture &c. as above. This species likes well-drained gritty soil in the rock garden, and a sunny position.

P. fruticosa.—A British shrub 2-4 ft. high, with brown stems and somewhat digitately pinnate leaves, glaucous and silky when young. Flowers in June and July, bright yellow, about $\frac{3}{4}$ in. across, at the ends of almost every branch. The variety *prostrata* has trailing stems, and *davurica*, a Chinese form, has smooth leaves.

Culture and Propagation.—This is a very striking plant and when in full blossom is exceedingly attractive. The branches and leaves are almost hidden with the abundance of yellow flowers. It likes well-drained ordinary soil and plenty of moisture, and may be increased by seeds, or cuttings of the young shoots in spring.

P. grandiflora.—This fine species is a native of the pastures and alpine regions of Europe and Asia. It grows 6-12 in. high, and has 3-foliate leaves of a grey-green hue. From 3 to 10 large bright yellow blossoms are borne on an erect stalk from May to August.

P. pedemontana, from the Southern Alps, is closely related, but has a more spreading habit and smaller leaves covered with a silky down beneath.

P. minima is a pygmy form of *grandiflora* found on the limestone mountains of

S. Europe at an elevation of 3000-6000 feet. The flowers are very small, and appear not only in May and June, but sometimes also in autumn.

Culture &c. as above. Easily increased by seeds and offsets.

P. heptaphylla.—An alpine species with spreading stems 6-12 in. high. The leaves are composed of 5-9 leaflets, and the large bright yellow flowers appear from May to August.

Culture &c. as above, p. 376.

P. hirta (*P. pedata*).—A handsome perennial 1 $\frac{1}{2}$ -2 ft. high, native of the mountains of S. Europe, and also found on the Atlas Mountains in N. Africa. The leaves are cut into 7 leaflets, and the rather large golden-yellow flowers continue to appear throughout the summer months.

P. astrakanica, *P. angustifolia*, and *P. obscura* are forms of this species.

Culture &c. as above, p. 376.

P. hopwoodiana.—A garden hybrid 1 $\frac{1}{2}$ ft. high, with oblong wedge-shaped, coarsely toothed, hairy leaflets. Flowers in June and July, beautiful salmon-apricot, edged with bright rose.

Culture &c. as above, p. 376.

P. multifida.—A handsome species 6-12 in. high, native of the mountains of Central Europe and Asia. The leaves are much divided and cut up, deep green above, and covered with a white down on the under surface. The yellow flowers are borne on slender stalks from May to July.

Culture &c. as above, p. 376.

P. nepalensis (*P. formosa*).—A handsome velvety hairy perennial 12-18 in. high, with deep green leaves composed of 5-7 oval lance-shaped toothed leaflets. The brilliant rosy-carmine flowers are produced freely from May to August, having rosy filaments in the centre tipped with blackish anthers. There is a variety called *nana*, similar to the type, but of a dwarfier and denser habit of growth.

Culture &c. as above. This species is closely related to forms of *P. argyrophylla*—notably *atrosanguinea*—and in conjunction with them has probably been instrumental in originating the beautiful double-flowered garden forms.

P. nevadensis.—A small trailing species, native of the Sierra Nevada in

Spain, where it grows in the clefts of the rocks at an elevation of about 10,000 ft. The leaves are composed of 5 leaflets clothed with a short, soft, silvery down, and the pale yellow flowers appear in May and June.

Culture &c. as above, p. 376.

P. nitida.—A native of S. Europe forming broad silvery cushions or carpets scarcely 2 in. high. The leaves are composed of 3-5 shining, silvery, obovate or wedge-shaped leaflets. Flowers in summer, soft delicate rose, but of a much deeper tint in the variety *atrorubens*.

Culture &c. as above. Although this species is easily increased by dividing the tufts, it seems as if plants raised from seed are hardier, and better in every way. This species is remarkable for having pink flowers, the majority of the other species being yellow or white. There is, however, a white-flowered form of *nitida* proper.

P. nivea.—A dwarf tufted species about 2 in. high, native of the mountainous regions of Europe, Asia, and N. America. The whitish downy leaves are composed of 3 spreading leaflets, the under surface of which is snowy-white. Flowers yellow, from May to July.

Culture &c. as above. This species likes gritty peat and loam in half-shaded parts of the rockery.

P. opaca.—A native of the mountains of Central and N. Europe, N. Asia, and N. America. The branches trail on the surface of the soil, and are furnished with large leaves composed of 5-7 leaflets covered with soft hairs. The yellow flowers appear in May and June, apparently on the surface of the ground, on account of the trailing stems.

Culture &c. as above, p. 376.

P. pyrenaica.—A showy Pyrenean species 6-18 in. high, sometimes covered with adpressed hairs, sometimes nearly smooth. Leaves 3-5-lobed, velvety or rather smooth, the lower ones on long stalks. Flowers in summer, deep golden-yellow; petals very round, and overlapping.

Culture &c. as above, p. 376.

P. recta.—A rather stiffish erect-growing species 12-18 in. high, native of the European mountains, with leaves composed of 5-toothed leaflets, and bearing numerous large primrose-yellow

flowers from May to September. There are several varieties of this fine species, the best known being *laciniata*, *macrantha*, and *palmata*.

Culture &c. as above, p. 376.

P. rupestris.—A native of the mountains of Central and S. Europe, with erect brownish stems 1½-2 ft. high, and pinnate leaves made up of 5-7 oblong toothed leaflets. The white flowers are borne in a loose panicle throughout the summer months.

Culture &c. as above, p. 376.

P. russelliana.—This is supposed to be a hybrid between *P. argyrophylla atrosanguinea* and *P. nepalensis*. In summer and autumn it bears its rich blood-scarlet flowers, nearly 2 in. across.

Culture &c. as above, p. 376.

P. Saxifraga.—A native of S. Europe 4-6 in. high. Leaves with 3-5 toothed or untoothed leaflets. Flowers in May and June, white, in corymbose heads.

Culture &c. as above, p. 376.

P. splendens.—A Pyrenean species with a short and rather woody branching rootstock, and slender stems forming a dense carpet scarcely 2 in. high. The 3-5 leaflets composing the leaves are of a glistening green above, with a silvery-white down beneath; and the beautiful white flowers appear singly on long stalks from May to July. Other white-flowered *Potentillas* are *P. Fragariastrum*, *P. petiolulata*, *P. micrantha*, and *P. pygmæa*.

Culture &c. as above, p. 376.

P. subcaulis.—A dwarf tufted species, native of the mountains of Europe, with branches spreading on the surface of the soil, and having leaves composed of 3 greyish downy leaflets. The yellow flowers appear from May to July, slightly above the trailing branches. Closely related to *P. cinerea* and perhaps only a form of it.

Culture &c. as above, p. 376.

P. unguiculata (*Ivesia unguiculata*). A pretty Californian perennial 9-12 in. high. Lower leaves 4-8 in. long, narrow-linear, with 3 closely packed leaflets clothed with silky white hairs. Flowers in July, pearly-white, ½ in. across, in slender, branched panicles.

Culture &c. as above, p. 376.

Tribe VI. POTERIEÆ.—Herbs or shrubs. Petals often absent. Stamens 1 or more. Carpels 1-3, enclosed by the calyx tube.

ALCHEMILLA (LADY'S MANTLE).—A genus with 30 species of erect or decumbent herbaceous perennials, with alternate, lobed, or palmate leaves. Calyx persistent, 8-10-lobed. Petals none. Stamens 1-4, inserted in the throat of the calyx. Carpels 1-4.

A. alpina.—A British plant 3-9 in. high, more or less clothed with silky hairs, except the upper surface of the 5-7-parted, roundish kidney-shaped leaves. Flowers from June to August, small, yellowish-green, in spiked and paniced cymes.

Culture and Propagation.—Alchemillas grow well in ordinary but well-drained soil, and are suitable for rocky gardens chiefly on account of their silky foliage. They may be increased by dividing the roots, or from seeds sown in spring.

A. sericea.—A Caucasian species about 6 in. high, larger in every part than *A. alpina*, but otherwise very similar.

Culture &c. as above.

MARGYRICARPUS.—A genus with 3 species of rigid branching shrubs. Calyx persistent, 4-5-lobed. Petals none. Stamens 2-3. Carpel 1, enclosed in the calyx tube. Fruit a leathery achene.

M. setosus.—A native of the Andes, 2-4 ft. high, with oddly pinnate leaves, and deep green, awl-shaped, reflexed leaflets. Flowers throughout the summer, green, minute, axillary, stalkless, succeeded by small white fruits which form the chief attraction of the plant.

Culture and Propagation.—This pretty little evergreen is a good rock plant, and its masses of white fruits look charming against a dark background. It thrives in rich sandy loam with leaf mould, and may be increased by cuttings in summer, in sandy soil under a glass; or by layering the branches.

ACÆNA.—A genus with about 30 species of somewhat creeping or decumbent, smooth or silky perennials with alternate, oddly pinnate, deeply toothed, or much cut leaves. Flowers at the ends of the branches or spicate, small. Calyx

3-7-lobed, persistent. Petals none. Stamens 1-10. Carpels 1-2, enclosed in the calyx tube.

Culture and Propagation.—The Acænas on account of their compact habit and creeping character are chiefly useful for clothing rockwork, or dry parts of the flower border. They grow well in ordinary soil, and may be increased by seeds, divisions, cuttings, or portions of the creeping rootlets. Besides the species described below there are many others to be found in botanical collections.

A. adscendens.—A Patagonian species with long creeping stems and ascending branchlets clothed with pinnate leaves which are silky beneath, and divided into elliptic obovate toothed leaflets $\frac{1}{4}$ -1 in. long. The roundish flower heads are dark purple, borne on long stalks in summer.

Culture &c. as above.

A. microphylla (*A. Nova Zealandiæ*). A small creeping evergreen herb, 1-2 in. high. Leaves 1-2 in. long, with 2-6 pairs of ovate toothed leaflets. Flowers in summer, inconspicuous, in close heads, with long crimson spines, which look very attractive. Native of New Zealand.

Culture &c. as above. In severe winters this is apt to get injured in exposed situations, but as a rule it soon recovers with the advent of mild weather. It is an excellent plant for covering the face of rockwork.

A. millefolia.—A distinct species with very finely cut, pale green leaves, and dullish spikes of inconspicuous flowers.

Culture &c. as above.

A. myriophylla.—A Chilian Fern-like plant 6-12 in. high, deeply cut, with slightly downy leaflets. Flowers in summer and autumn, in small, dull-coloured, rounded spikes.

Culture &c. as above.

A. pulchella.—A pretty bronzy-leaved species with inconspicuous flowers. It grows rapidly and is well suited for covering rockwork.

Culture &c. as above.

A. sarmentosa.—A vigorous perennial from Tristan d'Acunha with silky-haired

leaves and round heads of flowers borne on rather long woolly stalks.

Culture &c. as above, p. 381.

A. sericea.—A Chilean species with rather long leaves having 3-5 pairs of oblong wedge-shaped toothed leaflets, covered with soft silky hairs beneath. The greenish flowers appear in round heads on long stalks, but are not particularly attractive.

☞*Culture &c.* as above, p. 381.

A. splendens.—A stout-growing tufted species native of Chili. The pinnate leaves have 3-4 pairs of narrow obovate toothed leaflets densely clothed with silky white hairs on both surfaces. The rather inconspicuous flowers appear in long interrupted spikes during summer.

Culture &c. as above, p. 381.

ROSA (THE ROSE).—An important genus containing according to Bentham and Hooker not more than 30 or 40 really distinct species although as many as 180 have been described as such. Roses are more or less erect, climbing, or trailing, often prickly, smooth, silky, or glandular haired, woody shrubs, with alternate, oddly pinnate leaves, serrated leaflets and adnate stipules. Flowers solitary or in corymbs. Calyx 5-lobed; lobes simple or compound, inserted on the top of a roundish or pear-shaped, fleshy tube. Petals 5, very rarely 4, but in cultivated varieties many more owing to the transformation of the numerous stamens. Carpels numerous, inserted at the base of the calyx tube, free, with a simple projecting style and stigma. The ripe fruits (known as 'hips') consist of many 1-seeded carpels in a fleshy tube, which is analogous in structure to the Apple and Pear.

Garden Roses

Garden Roses are divided into many groups, all arising from comparatively few species. Years ago several of the groups mentioned below were great favourites, but the appearance of the so-called Hybrid Perpetuals and the Tea-Scented Roses, with their exquisite flowers, rapidly caught the public taste; and the older Roses, many of them very beautiful, free-flowering, and fragrant, began to disappear from gardens and likewise catalogues. Of late years, however, a revival has taken place, and some of the older sections with 'improved'

forms are finding their way into gardens again.

GENERAL CULTIVATION

Situation.—Roses should be grown in an open place, sheltered if possible, by surrounding vegetation at a distance, from tempestuous winds, especially the cold and bleak ones from the north and east. An aspect facing south-east or south-west is best, arranged in such a way that during the hottest hours of the day the Rose garden may obtain a little protection from the fierce rays of the sun by the cast shadow of trees or hedges.

Soil.—The ideal soil for Roses is a rich fibrous loam, 'unctuous loam' as it is called, that feels somewhat greasy when pressed between the fingers. It is not always possible to attain the ideal, nor is it really essential, as good Roses may be grown in ordinary garden soil, always provided the Rose-grower is industrious and cultivates it. Where soil is naturally light the addition of loam or even clay will improve its texture. Where cold and heavy, it must be well drained, and will be benefited by the addition of lime, sand, burnt earth, and leaf soil. But whatever kind the soil may be, it is essential that it must be thoroughly drained, dug or trenched well, and well manured. Too much importance cannot be attached to keeping the soil in which Roses are grown in a good condition, and the reader is referred to the various articles on Soil and its treatment in this work at pp. 61-69.

Manure.—Taken all round, farmyard manure is the best for Roses. For light soils cow manure is preferable to others, while horse manure is more suitable for heavy soils. And the ordinary Rose-grower will find it safer to keep the one or the other well incorporated with his soil. Pig manure is also excellent. The manures in a fairly well-rotted state may be spread over the Rose beds about November, and forked in the following spring.

There are many other manures employed, but they are either too expensive or too difficult to obtain at the right moment. Some of the chemical manures may be used with advantage, but they require to be carefully applied, the tendency with a beginner always being to give more to the plants than is good for them.

When trenching or digging Rose beds, about $\frac{1}{2}$ to 1 lb. of basic slag to the square yard may be added to the soil and well mixed with it. In ground that has been well dunged, a sprinkling of lime on the surface about November will be beneficial not only in liberating potash foods, but also in keeping the soil from souring and by acting as a check on slugs and other vermin. The addition of soot to the lime is an excellent practice.

Liquid manure and watering.—Perhaps the best and safest consists of horse or cow manure and soot made up in a tub or tank. Clean water diluted with this to the colour of pale ale may be given to the plants occasionally, say two or three times a week. Care must be taken, however, not to apply strong liquid manure in hot dry weather, unless the plants have previously had an application of clear water. The reason for this is that the thirsty roots would absorb the manurial matters too greedily and thus do the plants more harm than good. By first of all giving clear water, the roots absorb enough to fill the tissues of the plants, and when the liquid manure is given it is taken up in only small and beneficial quantities.

During the flowering period, one ounce of nitrate of potash and one ounce of phosphate of potash to one gallon of water makes a good stimulant for outdoor plants, but for plants in pots the same quantity of manure should have at least twice as much water. If the reader uses these manures, it will be wise to experiment with smaller doses than above prescribed, in case of causing injury; and when watering always soak the soil thoroughly, as merely wetting the surface is worse than useless.

Mulching and Hoeing.—In dry seasons, and especially in light soils, it is necessary to keep as much moisture in the soil as possible. A good mulching of cow manure, or even rotted leaves, not only retards excessive evaporation of moisture from the soil, but also prevents it being cracked and baked hard by the sun. Next to a good mulching with manure, the surface of the soil to the depth of an inch or two should be well hoed, the fine soil thus acting as a mulch, and checking evaporation.

Planting.—November is the best time for planting Roses. The ground should have been well dug and manured previously, and should be in a good friable

condition—neither wet and sticky, nor dry and dusty. A mild day should be chosen. The plants should be placed in the soil just deep enough to give the roots a firm hold, taking care to spread these out well, so that the soil gets in easily between the fibres. The soil should be trodden down firmly, but no manure should be put in direct contact with the roots. A layer, however, may be placed round the stem after planting to act as a mulch and a protection from frost at the same time. Dwarf or bush Roses should be about 12-15 in. apart, with 2 feet between the rows, and require no stakes; but standards or half-standards should have a stout stake attached at the time of planting to prevent injury from strong winds.

The diagram at p. 1032 will give an idea of the way in which not only Roses but other trees and bushes should be planted. The future success of a plant often depends upon whether it has been planted properly or not.

Before actually planting it is wise to carefully examine each plant, cutting away any injured roots. The branches also, if long and vigorous, may each be cut back to 3 or 4 'eyes' or buds, leaving the one next the cut pointing outwards. Some disagree with pruning at planting time, but there are sound physiological reasons for it, in addition to the fact that some of the most successful growers practise it.

As soon as possible after arrival the plants should be put in the soil. If they appear dried up or withered, a good watering all over will do them good; or they may be buried completely in the soil for a few days, when they will recover their plumpness. In the event of frosty weather, it is better to dig a trench, into which the plants may be put and have their roots covered with soil until planting time.

Roses on their own Roots.—Of late years there has been a demand for Roses on their own roots, instead of those which are usually budded or grafted. They may be a little more difficult to establish than others, but when once in a suitable position they grow well and have the great advantage of not being weakened by the strong suckers of ruder sorts. When purchased from the ground they may be planted in November, as recommended for the others; but if in pots, as they usually are, the best time to plant

them is from August to October. Each plant on removal from the pot to the open ground should have fine light or very sandy loam with a little decayed manure placed round it, to induce new roots to form more quickly.

No large garden should be without Hybrid Perpetual and Tea Roses on their own roots, as the shoots thrown up from the roots give a succession of bloom.

Own-root Roses may be obtained by means of cuttings or layers described below; but, to obtain a large stock in a short period, resort must be had to budding at first, so as to obtain as many plants as possible, from which cuttings may afterwards be taken.

Pruning Roses.—The pruning of Roses depends a good deal upon their natural features. The main object of pruning is, of course, to strengthen the plants, preserve or mould their shape, and impart more substance, size, and brilliancy of colour to the flowers. A couple of sharp knives, and a pair of pruning scissors for smaller shoots or ones difficult to cut with a knife, are the tools required, and a pair of gloves is not to be despised.

In pruning Roses the chief things to remember are: 1. That the strong growers should not be so severely pruned as the weaker ones. If strong growers are cut back close, they will send forth other strong shoots, full of leaf but lacking in flower. The branches of these, therefore, should be only slightly cut back to 5 or 6 eyes, but some of the others that crowd the centre or have taken awkward turns are to be cut away altogether, thus giving more strength to those left behind. 2. Weaker plants, being less able to support a large number of shoots than the strong-growing varieties, are to have every branch cut back to within 2 to 4 buds of the base—always taking care that the bud nearest the cut is pointing outwards, as the direction of the bud of course indicates the direction in which the new shoot will naturally develop. Varieties which flower freely require more severe pruning than those which flower poorly. Climbing Roses require practically no pruning, although now and again it will be advisable to take out a branch here and there. Tea Roses in the open air require only a little thinning out and shortening of the shoots. In the event of too many shoots appearing after pruning the least desirable may be pinched or

rubbed out with the finger and thumb. This is called 'disbudding,' and where exceptionally fine flowers are wanted, the practice may also be applied to the flower-buds—pinching off all except the one required on each branch. March and April are the best times for pruning, as a rule, but the season must always be taken into account, and the operation performed at the most suitable time about this period of the year.

Pegging down Roses.—Where a mass of bloom is required instead of a few large handsome blooms, the ripened shoots may be bent down to the soil, and pegged down here and there. This is as a rule best done in March, when the weather is mild and the danger of particularly severe weather is over. Strong stout stakes about 1½–2 ft. long may be driven into the soil around the Rose bush, leaving about 9–12 inches exposed. To this the shoots may be tied after bending down to the soil. Fresh shoots will spring up during the season, and the following year will bloom. The shoots that flowered the previous year may be cut away at pruning time or as soon as they have finished blooming, unless there is a chance of securing a second crop of blossoms in autumn.

Where pegging down Roses is practised a good deal of space is required for the plants. Three or four feet apart is not too much by the time the shoots are covered with flowers.

Labels.—Where a large number of varieties are grown it is well to have the plants labelled. An ordinary wooden label, not too large, painted white, and written upon while still damp, will be found as suitable as any. It may be attached with a piece of thin copper wire.

By having the plants correctly labelled nothing is left to treacherous memory or to chance in recording the behaviour of any particular variety. Some sorts flourish in one garden and fail in another under equally good circumstances, and it would be unfortunate if the failure or success of an incorrectly named Rose were credited to the real variety, which would probably behave quite differently under the same treatment.

PROPAGATION

Roses are increased by seeds, cuttings, layers, suckers, budding, and grafting. Seeds are only sown for the production of new varieties or hybrids. They are best

sown as soon as ripe, and when sown in the open must be protected from mice and birds. They are usually several months in germinating, but when the seedlings are large enough to handle easily they may be transplanted to quarters where they can be protected in winter.

Cuttings of all the strong-growing Roses root readily. In autumn ripened shoots about 9 or 12 in. long may be firmly inserted about 6 in. deep, much in the same way as Gooseberries and Currants, but all the buds should be left on. By spring they will nearly all be rooted and begin to grow. They are best left until the autumn and then moved to their permanent position.

Tea Roses and other more tender sorts may be rooted in the same way, but they require the protection of a cold frame during the winter months.

Layering is not much practised. The principle is as explained at p. 59. The plants obtained in this way are on the same level as those from cuttings by being on their own roots, and always safe from the suckers of an inferior variety. It is not essential to detach the rooted layers. They may be allowed to remain round the parent plant if space will permit, and when in bloom will present a magnificent sight.

Budding is the most popular means of increasing Roses, and almost every amateur who is fond of them likes to do his own budding. The stocks chiefly used are the Dog Rose—taken from the hedges, struck from cuttings, or raised from seed—the Manetti, and sometimes De la Griffère—a form of *R. polyantha*. Each kind has its champions, but there is a preponderance in favour of the Dog Rose or Briar.

In the south of France stocks of *Rosa polyantha* have been largely used and spoken of very favourably. Unfortunately, the seeds are somewhat difficult to procure, and this will prevent its becoming common. The seeds germinate in about a month's time, and Roses have been budded on July 2 on plants the seeds of which were sown on March 14. Plants on the *polyantha* stock are said to produce twice as many flowers as those on the *canina* (Dog Rose) stock.

Rose budding is generally practised in June and July, and the process is detailed at p. 58.

Grafting Roses is generally done in March out of doors, and is practised on old standard trees which have lost their tops; but it is scarcely worth the trouble.

Grafting may also be performed during the winter months in greenhouses. The stocks should be a little in advance of the grafts, by placing them in gentle heat some time before the operation is to be performed. Care must also be taken to secure sound wood in the grafts, and no shoots that have been injured by frost are of any use. By whip-grafting (see p. 52) a good union may be secured, afterwards tying both stock and graft up carefully and firmly, and placing in a warm close frame. Light is best excluded for several days until the union has almost taken place, but as soon as possible it should be admitted. Budding may be practised at the same season and under similar circumstances, and it is possible to have Roses in bloom by the following June, or about six months after the process.

Besides the above methods Roses may also be successfully increased by means of the single 'eyes' or buds. These are cut in the same way as for budding, but a portion of the leaf—say the 2 bottom leaflets—is retained and the wood is not detached from the bark, but is left to form a plate from which the roots are to be developed. The 'eyes' thus prepared are dibbled into sandy soil and placed in gentle bottom heat, soon root, and produce young plants. If kept growing without a check this is a good way of increasing Roses. The dormant buds attached to a piece of the old wood will also root in bottom heat if inserted about pruning time.

DISEASES AND PESTS

Mildew (*Sphaerotheca pannosa*).—If outdoor Roses are kept in a good state of cultivation—that is, if the soil is kept well tilled, the drainage perfect, and water abundant but not irregularly supplied—they do not suffer much with mildew. If they do, as often as not something is wrong in one or other of the departments mentioned, or perhaps an erratic season with sudden changes from hot to cold, drought or wet, is to blame. Any way, good cultivation is a great preventive. Soot sprinkled over the foliage when the dew is on it, and allowed to remain a few days before washing off, is an excellent if unsightly

remedy. Water, as hot as the hand can bear, with permanganate of potash dissolved in it I have found effectual if applied forcibly in a fine spray with a syringe.

Rose Rust (*Phragmidium mucronatum*), which disfigures the leaves of Hybrid Perpetuals with orange-yellow spots, and any other fungoid disease may be checked if not destroyed by the same means, or sprayed with liver of sulphur at the rate of about 1 oz. to 10 gallons of water.

Green Fly.—These are very fond of sucking the sap out of the young and tender shoots. A simple remedy is to syringe the plants with warm water in which a little soft soap has been added, and perhaps a little petroleum—about a teaspoonful to a gallon, thoroughly mixing the whole with the syringe.

The caterpillars of various moths also play havoc with Rose leaves, and the only sure remedy for these is to pick them off and kill them. It is a nasty process, but it must be done if the bushes are to retain anything like a decent appearance, and produce good flowers.

In the following pages brief descriptions are given of the best kinds of Roses for garden purposes. The varieties have been classified in sections usually adopted by rosarians, and in the more important classes, like the Hybrid Perpetual and Tea-Scented, they have been further subdivided according to the prevailing colour. No attempt has been made to make a short and select list of varieties. Such lists are often misleading, as they are for the most part based on the experience of a few individuals who usually record only the varieties that succeed or fail in their own particular garden.

HYBRID PERPETUAL ROSES.

It is a stretch of the imagination to call these Roses 'Perpetual' in the sense of lasting a long time in bloom, as comparatively few of them bear flowers after August. Indeed many of the beautiful Tea Roses remain much longer in bloom than the Hybrid Perpetuals. The latter are supposed to be the outcome of hybridising and selecting the best forms of *R. gallica* and *R. damascena*, the first step in the process being a hybrid named *R. Portlandica* after a Duchess of Portland who was a great lover of Roses in the eighteenth

century. In the course of time, however, they seem to have become so much mixed up with other sections that it is practically impossible to trace their origin.

The following is a list of the best Hybrid Perpetuals, but it must be borne in mind that new ones are being added every year by British and Continental Rose-growers. Those who seek novelties should therefore consult nurserymen's catalogues every season.

The varieties are arranged according to the predominant colour of the flowers, as it is often convenient to make a selection of a particular tint. For general culture and propagation see p. 382.

Shades of RED, CRIMSON, CARMINE &c.

Abel Carriere, rich velvety maroon, large and well formed.

Alfred Colomb (*Marshal P. Wilder*), bright carmine-red, large, full, and globular.

A. K. Williams, bright reddish-crimson, large, and of beautiful form.

Anna de Diesbach, brilliant carmine, beautifully formed, large and cupped.

Ards Rover, splendid crimson.

Auguste Neuman, velvety crimson, full, and good habit.

Bacchus, crimson, shaded violet-maroon, free.

Baronne de Bonstetten, intensely dark velvety crimson, medium size.

Beauty of Waltham, bright rosy crimson, large, cupped, and finely formed; very fragrant.

Black Prince, very dark crimson, richly shaded.

Camille Bernardin, bright red, large and full, fine form.

Captain Hayward, bright carmine-crimson, a new shade of colour; fine and full.

Charles Darwin, deep rich crimson, large and full.

Charles Gater, the finest new crimson Rose of late years, large globular flowers of brownish-red.

Charles Lefebvre (*Marguerite Brascac*, *Paul Jamain*), brilliant velvety crimson, cupped, and well formed.

Climbing Duchess of Norfolk, bright crimson, fine shape, fragrant.

Climbing Etienne Levet, fine carmine-red, globular, good habit.

Climbing Jules Margottin, bright scarlet, perfect shape, very fragrant.

Climbing Star of Waltham, deep crimson, good form, imbricated.

Climbing Victor Verdier, bright cherry-red, large and well formed.

Colonel Felix Breton, very rich violet-crimson, imbricated, good form.

Coquette des Blanches, white, tinged with pink.

Countess of Oxford, bright carmine-red, very large and full.

Crimson Queen, dark crimson, very fragrant.

Dr. Andry, brilliant red, shaded crimson, very effective.

Duchess of Bedford, rich velvety crimson, suffused with scarlet, perfect shape.

Duchess of Norfolk, bright crimson, fine shape, fragrant.

Duke of Albany, vivid crimson and good form.

Duke of Connaught, rich, bright velvety crimson, an exquisite colour.

Duke of Edinburgh, deep velvety crimson, good form and habit.

Duke of Teck, bright crimson-scarlet, large and full.

Duke of Wellington, dark crimson, large and full.

Dupuy Jamain, bright cerise, large free bloomer.

Earl of Dufferin, a rich dark crimson, shaded maroon, large and full.

Earl of Pembroke, bright brownish-crimson, margin bright red.

Eclair, very bright scarlet, globular, free and good.

Ella Gordon, bright cherry-crimson, large and full, good in autumn.

Empereur de Maroc, rich velvety maroon; a good dark variety.

Etienne Levet, fine carmine-red, globular, good habit.

E. Y. Teas, bright cerise, cupped, large and fine shaped.

Fisher Holmes, rich purplish-crimson, medium size, flowers beautifully imbricated.

François Levet, cherry-rose, fine shape.

General Jacqueminot, most brilliant crimson, large; a grand Rose. This variety has been crossed with *R. multiflora*, and has produced a charming hybrid called the 'Dawson Rose,' see p. 408.

Gloire de Margottin, brilliant red, an excellent climber.

Glory of Cheshunt, rich shaded crimson, cup shape, and free bloomer.

Grand Mogul, deep crimson, shaded with scarlet and black, good form. Also known as *Jean Soupert*.

Gustave Piganeau, brilliant carmine-lake, one of the very largest Roses, of excellent habit.

Haileybury, cerise-crimson, round.

Harrison Weir, rich velvety crimson, large recurved petals.

Helen Keller, brilliant rosy cerise, large, full and good autumnal flowers.

Henry Bennett, fine bright red, shaded with carmine, good form.

Horace Vernet, velvety reddish-purple, shaded dark crimson.

James Brownlow, brilliant carmine.

J. D. Paule, velvety crimson, cupped flower, and good for forcing.

Jean Cherpin, very dark plum colour, free and hardy.

Jean Liabaud, dark velvety crimson, large and full.

John Bright, pure glowing crimson, cup shape.

John Hopper, brilliant rosy crimson, lilac tint on back of petals, large, full and a free bloomer.

Jules Margottin, bright scarlet, large and very fragrant.

Lady Helen Stewart, bright and clear crimson-scarlet, fine upright form.

Lord Bacon, deep crimson, fine form, and abundant bloomer.

Lord Clyde, rich scarlet-crimson, large.

Louis van Houtte, velvety crimson, shaded with purple, globular shape.

Madame Charles Crapelet, bright cerise, full, fine shape.

Madame Thérèse Levet, bright cherry-rose, large and full.

Madame Victor Verdier, bright cherry-red, large and fine shape.

Mademoiselle Annie Wood, rich crimson, fine double.

Marie Baumann, bright carmine, the reverse of petals white, fine form.

Marie Rady (Comtesse de Choiseul), brilliant red, edged with white, nicely imbricated.

Marquis of Salisbury, rich crimson, perfect globular form.

Maurice Bernardin (Ferdinand de Lesseps, Sir G. Wolseley, Exposition de Brie), rich vermilion, very full, large globular shape.

Merry England, rosy crimson, striped with white.

Mrs. Harry Turner, dazzling crimson-scarlet, large, and beautifully imbricated.

Mrs. Jowitt, brilliant crimson, large and deep globular form. Also known as *Duc de Rohan*.

Paul's Carmine Pillar, bright rosy carmine, a good climber.

Paul's Cheshunt Scarlet, beautiful in bud, semi-double, vivid scarlet-crimson.

Pierre Notting, dark red with a violet tint, very fine.

Préfet Limbourg, dark velvety red, large and cupped.

Prince Arthur, very rich dark crimson, in the form of *General Jacqueminot*.

Prince Camille de Rohan (La Rosière), dark velvety crimson-maroon, richly shaded, large and full.

R. B. Cater, bright magenta-carmine, beautifully shaped, early and free flowering.

Red Gauntlet, bright scarlet-crimson, good shape.

Reynolds Hole, rich crimson, shaded maroon, fine globular form.

Robert Duncan, bright rosy lake, perfectly formed, free blooming and continuous.

Rosieriste Jacobs, rich velvety red, clouded with black, good form.

Royal Scarlet, a single scarlet variety, blooms produced in great abundance, useful for bedding.

Salamander, bright crimson-scarlet, very vivid, large and full.

Sénateur Vaisse, dazzling scarlet, fine form and large, a free bloomer.

Sir Rowland Hill, a rich deep port wine colour, large, full and sweetly perfumed.

Souvenir de Henry Vy, dark crimson and good form.

Star of Waltham, deep crimson, large, full and deeply imbricated

Sultan of Zanzibar, blackish-maroon, edged with scarlet, large globular flowers.

Suzanne Marie Rodocanachi, soft rosy cerise, very distinct and beautiful.

The Shah, very bright red, shaded, of medium size.

T. W. Girdlestone, brilliant vermilion, thoroughly distinct, large, full and well formed.

Tom Wood, cherry-red, large, full and perfectly formed, flowers very freely.

Ulrich Brunner, cherry-crimson, very large blooms, effective.

Victor Hugo, brilliant crimson, free-flowering.

Victor Verdier, cherry-rose, shaded with carmine, large, fine and very free.

Waltham Standard, brilliant carmine, shape and petal of *A. K. Williams*, fine foliage and a grand exhibition Rose.

Xavier Olibo, velvety black, shaded with amaranth, large globular form.

Shades of PINK or ROSE

Abel Grand, beautiful silvery rose, glossy and fresh in colour, large and full.

Alphonse Soupert, bright pink, very large and free.

American Beauty, deep rose, large, globular, and good shape; deliciously scented.

Anna Alexieff, bright rose, large, very free bloomer.

Baroness Rothschild, very light rosy pink, changing almost to white; fine shape, and free.

Clara Cochet, bright pink, clear in colour, globular shape.

Climbing Edouard Morren, glossy pink, delicate in colour.

Climbing La France, satiny pink, a good climber.

Climbing Marie Cointet, bright rose, changing to blush.

Climbing Queen of Queens, pink, with blush edges, free bloomer.

Clio, flesh colour, shaded rosy pink, large and globular.

Comtesse de Serenyi, delicate pink, shaded rose, large compact flower of splendid shape.

Countess of Rosebery, soft carmine-rose, large and full, cupped form, hand some foliage.

Dowager Duchess of Marlborough pure rose, large globular flower, beautifully scented.

Duchesse de Morny, clear bright rose and fine shape.

Duchess of Fife, soft silvery pink, a beautiful shade, finely cupped.

Duchesse de Vallombrosa, light rose-peach passing to white, large globular flower.

Duchess of York, pale pink flushed with rose.

Edouard Morren, brilliant glossy pink, fresh and clear, very large.

Egeria, beautiful light silvery peach, good shape.

Elie Morel, lilac-rose, large and full, perfect form.

Ellen Drew, silvery pink, quite a distinct Rose. A sport from *Duchesse de Morny*.

François Michelin, deep rose, reverse of petals silvery.

Heinrich Schultheis, delicate pinkish-rose, large and fine form.

Her Majesty, flesh colour, large massive flowers, reflexed.

Jeannie Dickson, rosy pink, edged silvery white, good form.

La France. Perhaps no Rose is better known or more highly valued for general planting, both in open ground or under glass, than *La France*. It is a Hybrid Tea, but usually classed with the Hybrid Perpetuals; very beautiful in form and colour, which is a lovely shade of peach blossom, changing to amber-rose, elegantly tinged with crimson.

Lawrence Allen, soft pink, lighter shading, large and full.

Madame Gabriel Luizet, light silvery pink, edges of petals shading off to white, large and good.

Madame Laurent, bright rosy colour and globular form.

Madame E. Michel, fine bright rose very large and full, like *Madame Gabriel Luizet*, but deeper in colour.

Madame Vidot, transparent flesh, shaded with rose, large and full.

Mademoiselle Eugénie Verdier (*Marie Finger Amadis*), bright flesh colour, large, full, good habit.

Magna Charta, bright pink, globular, very large and fine habit.

Marchioness of Downshire, beautiful satin pink, shaded with rose, large and full.

Marchioness of Dufferin, beautiful rosy pink, very large, full and fine form.

Marchioness of Lorne, a very rich and fulgent rose colour, slightly shaded in centre with vivid carmine.

Marguerite de St. Amand, bright pink, large, full and imbricated.

Marie Coindet, bright rose, changing to blush, pretty reflexed form, very free.

Marie Verdier, bright satiny pink, beautifully cupped.

Marquise de Castellane, bright rose, large and fine.

Mrs. George Dickson, delicate soft pink, beautiful in bud.

Mrs. John Laing, soft pink, a large and beautiful Rose of globular shape.

Mrs. R. G. Sharman Crawford, deep rosy pink, outer petals shaded with pale flesh, free bloomer.

Mrs. W. Rumsey, fine rich pink, good for cutting.

Monsieur Noman, pure rose, large and magnificent.

Paul Neron, deep rose, large and good shape.

Pride of Waltham, delicate flesh, shaded with bright rose.

Princess Louise Victoria, flesh changing to blush; makes a good pillar Rose.

Queen of Queens, pink, with blush edges, good form, and very free bloomer.

Spenser, satin pink, very large and full.

Shades of WHITE or BLUSH-WHITE

Baronne de Maynard, pure white, moderate size, good form.

Bladud, silvery white, full and globular.

Boule de Neige, pure white, good form, fine in bunches.

Elise Boelle, white, centre peach, free bloomer.

Helen Paul, pure white, sometimes shaded pink.

Impératrice Eugénie, a fine white.

Madame Alfred de Rougemont, white, tinted with pink, moderate size, free bloomer.

Madame Fanny de Forrest, beautiful white, free bloomer.

Madame Freeman, white, shaded rose.

Madame Lacharme, pure white, large and full, blooms freely.

Mademoiselle Bonnaire, white shaded blush, medium size, fine form, requires close pruning.

Marchioness of Londonderry, ivory white, shell-shaped and reflexed.

Marquise de Montemart, blush-white, splendidly double.

Mavourneen, delicate silvery white, shaded rose-flesh.

Merveille de Lyon, white, slightly tinted with rosy peach, splendid size and shape.

Miss Ingram, white with a blush centre.

Perle des Blanches, pure white, medium size, good shape.

Violette Bouyer, white, shaded delicate flesh colour, large globular flowers.

White Baroness, pure white, large full flower, very fine.

TEA-SCENTED ROSES.—The Tea Rose—perhaps the most exquisite of all beautiful Roses—is supposed to be descended; chiefly from *R. indica* and its variety *odorata*, remarkable for the fragrance of its blossoms. Like the Hybrid

Perpetuals, they have been selected and crossed and brought to great perfection both in this country and on the Continent.

Unfortunately they are not quite so hardy as the Hybrid Perpetuals, and most of them require a slight protection of litter or bracken or farmyard manure around them during severe winters, especially in northern parts of the kingdom, and in other bleak localities.

Although the kinds enumerated below are roughly grouped according to their colours, it is simply impossible to do justice in print to the many beautifully tender and delicate shades of colour in the Tea Roses as a class. As they are a good deal mixed up with the Noisette Roses, the reader would do well to consult both lists when looking for any particular variety, as it may be in one or the other according to the views of certain rosarians.

For general culture and propagation see p. 382.

The following is a list of the best kinds:—

Shades of PINK, ROSE, and CRIMSON

Adam (President), blush-rose, very sweetly scented, large and full.

Aline Sisley, violet, shaded red, medium size.

Alphonse Karr, bright peachy crimson, semi-double and free.

Anna Olivier, rosy flesh, base dark, fine form and very distinct.

Beauté Inconstante, coppery red, shaded with carmine and yellow.

Bridesmaid, a strong, vigorous form of *C. Mermet*, of deep pink colour.

Catherine Mermet, fine flesh colour, full and perfect form; one of the finest. Best grown in bold groups, as individual plants have a somewhat naked appearance.

Clara Watson, salmon tinted pink, a good Rose.

Cleopatra, pale pink, edged with rose, pretty in bud.

Clotilde, rose and white, centre sometimes violet, double.

Comtesse de Nadaillac, bright, flesh-coloured rose, with coppery yellow or apricot base, very fine in the bud and open flower.

Comtesse de Panisse, bright flesh colour tinted coppery rose, very full, and good form.

Comtesse Riza du Parc, beautiful

metallic rose, changing to pink, large globular form, a pretty colour.

Corinna, flesh colour, shaded with rose and suffused with tawny copper.

Dr. Rouges, deep red with orange shading, long semi-double bud, distinct.

Duc de Caylus, deep rosy magenta, flushed with creamy white and canary-yellow.

Duchess of Edinburgh, deep rosy crimson, large and full, good for forcing.

Elise Fugier, very pale lemon-white.

Emanuel Geibel, a sport from *Madame Falcot*, but much deeper in colour.

Empress Alexandra of Russia, rich lake shaded with orange, large and globular, distinct.

Ernest Metz, delicate carmine-rose, reverse of petals deeper, well formed.

Ethel Brownlow, bright salmon-pink, shaded with yellow at base of petals.

François Dubreuil, beautiful crimson.

General Billot, pale violet flushed with amaranth.

Goubalt, bright rose, centre buff, large and full.

Gustave Chandos, salmon-red, very free, hardy and vigorous growth.

Homer, rose with deeper centre, a pretty crimped flower.

La Nuance, delicate flesh colour, fine form, very pretty.

Madame Berard, light, rich salmon, large reflexed flowers, very fine.

Madame Camille, delicate salmon-pink, large and full.

Madame Charles, bright apricot, beautiful in bud.

Madame Cusin, rose-purple with yellow centre, fine form.

Madame de St. Joseph, salmon-pink, large and double.

Madame de Watteville, pale lemon, with margin of pink, passing to deep rose, very distinct and free.

Madame Falcot, dark apricot, large and very fine.

Madame Lambard, fine bright red, sometimes paler later in the season, fine imbricated form. One of the best Tea Roses.

Madame Marie Ducher, transparent rose, very large, fine form and good habit.

Maman Cochet, large and full, pink shaded with salmon-yellow, a good novelty.

Marquise de Vivens, a distinct and beautiful bright pink rose, with semi-double flowers, deliciously fragrant.

Mrs. Pierpont Morgan, like *Madame Cusin*, with deeper shade of colour.

Mrs. Wilson, colour deep lemon-yellow, petals tipped with rose.

Papa Gontier, bright rosy crimson, exceedingly pretty in bud.

Princesse Alice Monaco, outer petals pink, centre salmon-yellow.

Safrano, bright apricot, changing to buff, beautiful in bud.

Souvenir de Président Carnot, very free, bud long, rosy flesh colour, large and full, perfect form.

Souvenir d'un Ami, salmon-rose, large, and fine shape. This is a vigorous and free-flowering Rose, and although the blossoms hang their heads somewhat, they are very fine.

Waban, carmine-pink, splashed with flaming madder-red.

Shades of YELLOW

Albertine Bouquet, pale lemon yellow.

Amazone, golden yellow, long pointed buds.

Belle Lyonnaise, deep canary yellow, changing to salmon, large, globular, and full.

Climbing Perle des Jardins, fine orange yellow, good climber.

Comtesse Dusy, pale lemon yellow.

Duchess Marie of Ratibor, creamy yellow with a reddish centre; strong grower.

Etoile de Lyon, fine sulphur yellow, with brighter centre, large and perfectly formed.

Francisca Kruger, coppery yellow, shaded with peach, large and full.

Gloire de Dijon, buff, shaded with salmon, orange centre, very large and good form. A splendid Rose for all purposes.

Gloire Lyonnaise, clear chrome yellow, changing to silvery white, large, full, and good shape.

Golden Gate, very pale lemon yellow, edged faintly with pink; not a very strong-growing variety.

Gustave Regis, canary yellow with orange centre, beautiful in bud.

Henriette de Beauvan, bright clear yellow, free; a good climbing Rose.

Innocente Pirola, light fawn, changing to white, beautiful shape.

Isabella Sprunt, sulphur yellow, beautiful in the bud, free bloomer.

Jean Ducher, salmon yellow, shaded rosy pink, large, full, and globular.

Jeanne Forgeot, golden yellow, shaded nankeen and rose.

La Boule d'or, golden yellow, but requires hot seasons to come to perfection
Le Soleil, beautiful chrome yellow; blooms freely in autumn.

Louise de Savoie, lemon yellow, very large and double.

Ma Capucine, bronze yellow, beautiful in bud, a charming button-hole Rose.

Madame Caroline Kuster, beautiful orange yellow, large, globular and free-flowering. Often classed as a Noisette.

Madame Chedane Guinoisseau, very bright yellow, exquisite colour and shape.

Madame Eugène Verdier, very deep yellow, distinct and attractive.

Madame Germaine Trochon, yellow, shaded nankeen yellow, large and full.

Madame Margottin, beautiful citron yellow, centre rosy peach, large and well-formed.

Narcisse, fine pale yellow, free and full.

Perfection de Monplaisir, deep canary yellow, lovely, medium size.

Perle des Jardins, fine orange yellow, very large and fine form; one of the very best.

Perle de Lyon, deep yellow, sometimes tinted apricot, large, very full and fine form.

Princess Beatrice, rich golden yellow, paler towards outside of flower, large and well formed.

Princess of Wales, rosy yellow, deeper centre, large and perfect form.

Raoul Chauvry, yellow; shaded apricot; flowers large, buds very long.

Sappho, fawn colour, shaded with yellow and tawny buff, globular, large and full, very distinct.

Souv. de Jeanne Cabaud, copper-coloured, shaded yellow and carmine.

Sulphureaux, fine sulphur-rose, large and full.

Sunset, deep orange yellow, perfect form; a very fine Rose.

Shades of WHITE, or WHITE TINTED WITH ROSE, PINK, SALMON, &c.

Annacharton, cream, edged with carmine and rose; very free.

Climbing Devoniensis, white, with yellow tint, fine, of rampant growth.

Climbing Niphetos, beautiful pure white, a vigorous grower, flowers on the lateral shoots.

Devoniensis, white, with yellow tint, large and fine.

Enchantress, white, slightly tinged with yellow in the centre, globular; strong and free.

Etendard de Jeanne d'Arc, creamy white, changing to pure white, good shape; a white *Gloire de Dijon*.

Hon. Edith Gifford, white, slightly tinted, with yellow base, a grand Rose.

Letty Coles, white, with pink centre, novel and distinct.

Madame Angele Jacquier, yellowish-white, with rose centre, large and full.

Madame Bravy (*Alba rosea*; *Madame de Sertot*; *Josephine Malton*), cream, centre blush, large, and beautifully formed.

Madame Hippolyte Jamain, white, with copper-coloured centre, distinct.

Madame Hoste, yellowish-white, centre deeper yellow, large, perfect form.

Madame Maurin, white, shaded salmon, large and full.

Madame Willermoz, white, with salmon centre, fine.

Marie Guillot, fine white, tinted with yellow, large, full and fine form.

Marie Van Houtte, yellowish-white, edged with bright rose, large, full and beautiful. A splendid Rose for massing in beds.

May Rivers, white, slightly tinted with lemon, darker in centre.

Muriel Grahame, pale cream flushed with rose, a sport from *Catherine Mermet*.

Niphotos, beautiful white, large and full; one of the best.

Rubens, white, shaded with rose, good form. An excellent garden Rose.

Souvenir d'Elise, creamy white, with blush centre, very beautiful.

Souvenir d'Elise Vardon, white, with salmon centre, sometimes edged with rose.

Souvenir de Paul Neron, white, tinged with rose, full and perfect form.

Souvenir de S. A. Prince, a pure white sport from *Souvenir d'un Ami*, one of the best white Tea-Scented Roses.

Sylph, flowers ivory white tinted peach colour, magnificent exhibition Rose.

The Bride, fine white, large and full; one of the best.

White Maman Cochet, a white sport of *Maman Cochet*, a grand new variety.

HYBRID TEA-SCENTED ROSES

These have been obtained by crossing the Tea Roses and the Hybrid Per-

petuals. They are hardier than the ordinary Tea Rose, and may be grown like the H.P.s. For general culture and propagation, see p. 382.

Shades of CRIMSON, ROSE, or PINK

Bardou Job, bright glowing crimson, almost single, a free bloomer.

Camoens, bright China rose, most taking colour, fine and large.

Captain Christy, delicate flesh colour, large and full.

Caroline Testout, light salmon-pink, very large and globular.

Cheshunt Hybrid, cherry-red, large and full, beautiful in bud, good habit, one of the finest climbers.

Climbing Captain Christy, delicate flesh colour, large and full.

Countess of Caledon, rich carmine-rose, great substance; strong growth and free branching habit.

Danmark, rosy pink, similar to *La France*, but brighter in colour, round ball-shaped flower, large and double.

Lady Mary Fitzwilliam, light rosy pink, with deeper centre, a splendid Rose.

La Fraicheur, carmine-rose, shaded lighter, fine cup-shaped flower, very long buds, a grand Rose.

Longworth Rambler, light crimson, semi-double, very vigorous. A good autumn-flowering climber. Also known as *Deschamps*, and classed with the *Noisettes*.

Madame Cadeau Ramey, rosy flesh shaded with yellow, a pretty combination of colours.

Madame de Tartas, bright rose, medium size, very free.

Marquis de Litta, carmine-rose, vermilion centre, large, full and cupped.

Meteor, dark red, fine and very free.

Mrs. W. C. Whitney, clear deep pink, large, full and well-formed flowers.

Mrs. W. J. Grant, bright rosy pink, large, full and beautiful.

Papillon, rosy colour, curious twisted petals, very pretty.

Princess May, a clear soft opaque pink, large, full, and globular.

Reine Marie Henriette, deep carmine, large, full, and well-formed; a good climber.

Reine Olga de Wurtemberg, a vivid red, good-shaped flowers, but only semi-double.

Viscountess Folkstone, creamy pink,

semi-climbing habit, very free-flowering, and early bloomer.

W. F. Bennett, brilliant crimson, large and free, useful for cutting.

Shades of WHITE or CREAMY-WHITE

Antoine Rivoire, cream with orange-yellow centre, large and full.

Augustine Guinoisseau, a white *La France*, very lightly tinted with pale rose.

Charlotte Gillemot, ivory white, large and full, and perfect imbricated form.

Climbing Kaiserin Augusta Victoria, cream shaded lemon, a climbing sport of great vigour.

Gloire de Bordeaux, silvery white, large and full.

Grace Darling, white, shaded and edged with rose, very good and distinct.

Grand Duc Adolphe de Luxembourg, white, blooms in clusters, semi-double.

Kaiserin Augusta Victoria, white, slightly shaded lemon, deeper in centre, a distinct and beautiful rose.

Lady Alice, creamy white, large and fine form.

Madame Joseph Combit, creamy white, shaded rosy peach, flowers large and full.

Madame Jules Finger, creamy white, shaded pink with salmon centre, large and full.

Margaret Dickson, white with pale flesh centre, good form.

Marjorie, white with pink tint, free and continuous bloomer.

Miss Ethel Richardson, almost a pure white, pale flesh centre, large imbricated form, very free.

White Lady, creamy white, one of the most handsome and effective Roses grown, quite distinct.

NOISETTE ROSES (*R. NOISETTIANA*).—This group is supposed to have arisen by crossing the Tea Rose or the Bengal Rose with *R. moschata*, the Musk Rose, by a French gardener named Philippe Noisette, who sent it to France from America, and who may possibly have used the climbing native American *R. setigera* instead of *R. moschata*. The climbing character of some of the Noisette Roses rather favours this idea, but the sweet fragrance is a point in favour of *R. moschata* parentage. Some varieties are occasionally classed as Tea Roses, and it may be as well to consult both lists

when looking for any particular variety. The following appear in most catalogues as Noisette Roses. For general culture and propagation, see p. 382.

Aimée Vibert, pure white, beautiful and full, flowers in large clusters. A good climbing or pillar Rose, also as a standard bush.

Alister Stella Gray, a climbing Rose, in the way of *W. A. Richardson*, with bunches of straw- and orange-yellow flowers.

Bouquet d'Or, deep salmon-yellow, with copper centre, large and full.

Céline Forestier, pale yellow, with deeper yellow in centre, free-flowering, opens well out of doors.

Cloth of Gold, deep yellow, edges sulphur, a splendid Rose when it can be flowered; requires a south wall. Rather tender. It requires no pruning beyond cutting out weak growths.

Comtesse de Galard Béarn, canary-yellow, free-flowering and a good climber.

Duchess of Mecklenburg, pale yellow, produced very freely in bunches.

Fellenberg, rosy crimson, very free bloomer.

Fortune's Yellow or *Beauty of Glazenwood*, buff striped with crimson. Rather tender, and is best grown under glass except in the mildest parts.

Jaune Desprez, light colour, fawn centre, good climber, but looks well drooping from a standard stock.

Lamarque, pure white, with sulphur-yellow centre. Rather tender, is best grown under glass except in the mildest parts.

L'Idéal, yellow and metallic red, streaked and tinted golden-yellow, quite distinct. Rather tender, and best grown under glass except in the mildest parts.

Madame Carnot, fine golden-yellow, seedling from *W. A. Richardson*, with deeper centre, edge of petals paler. It is rather tender, and is best grown under glass except in the mildest parts.

Madame Pierre Cochet, centre rich golden-yellow, shading off to yellowish-white, a profuse bloomer. Rather tender, and best grown under glass except in the mildest parts.

Maréchal Niel, bright rich yellow, large, free and fine form; the best yellow Rose in cultivation. Rather tender, and is best grown under glass except in the mildest parts. It is subject to canker, and is probably best on the Briar stock.

Princess Mecklenburg, lemon-white, cluster Rose.

Rève d'Or, deep yellow and buff; a good climber. It is almost an evergreen and breaks into good growth from the base.

Solfaterre, sulphur-yellow, large. Rather tender, and is best grown under glass except in the mildest parts.

Triomphe de Rennes, light canary-yellow, a free bloomer.

White Maréchal Niel, a white form of *Maréchal Niel*, with a similar growth and habit, and quite as tender.

Wm. Allen Richardson, beautiful orange-yellow, flowers small, but very pretty. It seems to grow better on the Briar stock.

CHINA, BENGAL, or MONTHLY ROSES.—Supposed to be derived from *R. indica* and its varieties, and first introduced into England about 1770–1780 from Canton. Hence the name of China Rose.

The flowers are usually produced in clusters or corymbs, and in great abundance.

Culture and Propagation.—They are well adapted for planting in beds on lawns, and flower profusely almost into winter. They like warm, light soil but not dryness, and may be severely pruned except when a few shoots on a wall are required to produce early flowers. In severe winters it would be wise to give some protection with dry leaves, litter &c., as in the case of the Tea Roses. For general culture and propagation see p. 382.

The following is a selection:—

Abbé Mioland, reddish-purple; vigorous grower.

Archduke Charles, clear rose changing to crimson.

Blairii No. 1, blush-pink, large and double, a good climber.

Climbing Cramoisie Supérieure, a bright and effective climber.

Common Blush, blush colour. This is really the best of all the Monthly Roses. It flowers profusely, and may be grown as a climber or for massing in beds, borders, banks &c.

Cramoisie Supérieure, bright crimson, very effective.

Ducher, pure white, good form and free.

Duke of York, rosy pink, edged white, good habit.

Fabvier, brilliant crimson, semi-double, very effective.

Irene Watts, varying from salmon-white to pale pink, with long pointed bud.

Laurette de Messimy, delicate rosy pink, shaded with yellow, most pleasing and effective. An excellent variety for grouping in beds.

Little Pet, or *White Pet*, produces clusters of white flowers in great profusion. Very dwarf habit.

Madame Eugénie Resal, colour variable, ranging from coppery red to bright rose. It is a seedling from *Laurette de Messimy*.

Mrs. Bosanquet, delicate pale flesh, clustering very beautiful.

Nemesis, bright crimson, free and good.

Old Crimson, deep bright crimson.

Queen Mab, soft rosy apricot, centre shaded with orange, outside tinted with red. The unopened buds are charming and very useful for sprays, coat-flowers, &c.

Red Pet, similar in habit to *White Pet*, but of a rich crimson colour changing to blackish-maroon in autumn.

Viridiflora, the green-flowered Rose.

BOURBON ROSES (*R. INDICA BORBONICA*).—A very useful group of Garden Roses, blooming in the autumn freely and constantly in favourable situations. They look well grown as standards, but are more effective grown in bold masses or in beds in good well-drained soil. They require very little pruning as a rule, and may be readily increased by means of cuttings. Grown on the Briar stock they come into bloom, however, somewhat later than when on their own roots. For general culture and propagation see p. 382. They are somewhat confused with other sections, but the following is a selection:—

Acidalie, blush-white of good size. This variety has slender graceful shoots, and a somewhat climbing habit.

Armosa, pink, in clusters, very free and continuous.

Baron Gonella, pinkish-lilac inside, deep rose outside. A beautiful free-flowering Rose.

Comtesse de Brabantane, flesh-coloured, fine double-flowered form; vigorous grower.

Comtesse de Rocquigny, white flushed with pink salmon; flowers produced in large trusses.

Gloire des Rosomanes, beautiful rich crimson, semi-double; vigorous grower.

Kronprinzessin Victoria, soft prim-

rose-yellow. A very beautiful sport from *Souv. de la Malmaison*.

Lorna Doone, magenta-carmine, shaded with scarlet, very handsome and sweet.

Lowise Odier, bright pink, very free and hardy.

Mdme. Isaac Pereire, beautiful vivid carmine, full, and of immense size, blooms freely, growth very vigorous, one of the finest. May be grown as a bush or standard.

Mdme. Pierre Oger, white shaded and edged with pink; exquisite form.

Mrs. Paul, blush-white, with rosy peach shading, large Camellia-like flowers of great substance, growth very vigorous and good autumnal bloomer. It is a seedling from *Mdme. I. Pereire*.

Mrs. Bosanquet, pale flesh colour; very free in growth and blossom either as a bush or standard.

Purity, pure white, faintly flushed centre, growth semi-climbing.

Queen, delicate salmon or buff, fragrant. As many as 20 blossoms are often borne on one shoot when well grown.

Queen of Bedders, rich crimson, very free; dwarf habit.

Reine Victoria, bright rose, medium size; good form.

Robusta, velvety crimson shaded purple. The shoots grow 6 to 8 ft. long in one season. A good climber or pillar Rose.

Sir Joseph Paxton, bright rose, rather flat, but very free and vigorous, and excellent for town gardens.

Souv. de la Malmaison, clear blush, very large and double, superb. One of the very best.

Souv. de la Pierre Dupuy, fine deep crimson, shaded with purple, very large and double, a fine pillar Rose (Hybrid Bourbon).

BOURSALT ROSES (R. ALPINA).—

The Boursalt Roses are gradually disappearing, and many rosarians consider them small loss. And yet I know an old shed, the end of which has for many years been covered with the old crimson *Amadis*, and at a distance it looks simply charming. But closer inspection reveals a very coarse flower indeed, and it is perhaps only just that it should give place to better things.

PROVENCE or CABBAGE ROSES.—These beautiful Roses are derived from *R. centifolia*, and although it is not quite clear why they are called

'Provence' Roses (as they did not originate in Provence but in the East) that name at least sounds better than the equally obscure appellation of 'Cabbage' Rose. Many years ago a double yellow Provence Rose used to be common in gardens, but now it seems to have disappeared, and is not to be found in modern catalogues.

Culture and Propagation.—The Provence Roses enjoy a rich well-manured soil, and may be severely pruned. They are best on their own roots, but also succeed well on the Briar stock. For general culture and propagation, see p. 382.

The following varieties, including the miniature Provence or Pompon Roses, are obtainable:—

Common Provence, rosy blush, large and full.

Crested or Cristata, rosy pink, with paler edges, beautiful.

Forcing Provence, flesh colour, large.

Red Provence, crimson, large and full.

Unique or White Provence, beautiful white, large and full.

York and Lancaster, white, striped with red, sometimes half red and half white.

MOSS ROSES (R. CENTIFOLIA MUSCOSA).—The Moss Roses are a charming class of hybrids derived like the Provence Roses from varieties of *R. centifolia*, and readily distinguished by the green, mossy calyx—the moss being transformed hairs of the calyx, and sometimes of the flower and leaf stalks. Of late years they have been somewhat neglected owing doubtless to the appearance of so many beautiful Tea and Hybrid Perpetual kinds, but wherever a large collection of Roses is grown the mossy section is well worth being represented. The original old red Moss Rose, from which all the other varieties have been developed, appears to have been sent to England about 1735, from Italy. It was grown by a nurseryman named Wrench at Broomhouse, Fulham, for 20 years without attracting much attention, but was afterwards taken in hand by another nurseryman named Shailer of Chelsea. He produced the first white Moss Rose in 1788, or rather it was a sport from the red variety, and he budded it on the white Provence Rose. A striped variety next appeared, and the cultivation of Moss Roses at high prices became extensive in the neighbourhood of Chelsea and Fulham.

Culture and Propagation.— Moss Roses like the best of well-drained and well-manured soil to produce their flowers in abundance. Some flower in early summer, others—known as 'Perpetual'—in autumn, thus giving a long season of bloom. They may be grown as dwarf standards or bushes and do well on their own roots, or budded on the seedling Briar. They enjoy a rich fibrous loam, with which has been incorporated plenty of well-rotted manure. About every third or fourth year they will be improved by transplanting, as they become stronger and flower more freely. They like severe pruning as a rule, but discretion must be used and notice taken of weak and strong growing varieties. They like a good mulching of manure, and may be treated generally as advised at p. 382.

The following are among the best varieties:—

SUMMER-FLOWERING VARIETIES

These bloom in May, June, and July, and are all favourites on account of their peculiar and beautiful appearance.

Alice Leroy, blush shaded with rose, large and double.

Baronne de Wassenaer, deep rose, very early, double, and showy.

Captain Ingram, dark velvety purple, fine.

Celina, flowers rich crimson, produced in panicles of 8 or 9, and with a well-mossed calyx.

Common Moss Rose, pale rose, large and free.

Comtesse de Murinais, white, large and double, each shoot with clusters of blossom.

Crested, pale rosy-pink, buds beautifully crested, distinct.

Crimson Globe, deep crimson, globular shaped flowers, and beautifully mossed.

Gloire de Mousseuses, blush, large and full, one of the best.

Gracilis or *Prolific*, deep pink, globular, large, full, and of good shape; an excellent kind.

Henry Martin, shaded velvety carmine, fine.

Lanei, deep brilliant rose, a beautiful round handsome bud fairly well mossed.

Little Gem, small double crimson flowers; charming miniature Moss Rose. This is a good variety for growing in pots. The buds are very small and very mossy, but produced in great abundance.

Luxembourg, dark purplish-crimson, beautiful.

Marie de Blois, bright rose, large, full; well mossed, handsome buds.

Nuits d'Young, velvety purple, very double.

Princess Royal, flesh, very distinct, small and pretty.

Princess Alice, deep bluish-red, centre pink, buds well mossed.

Reine Blanche, white, a good variety, pale green foliage.

White Bath, paper-white, beautiful, large and full.

'PERPETUAL' AUTUMN-FLOWERING VARIETIES

The following are all autumn as well as summer blooming kinds, and are of great merit. They should have good rich soil, and should be closely pruned.

Blanche Moreau, pure white, of perfect form, well mossed, the sepals passing beyond the bud nearly an inch, and forming a vivid contrast to the flowers.

Eugène Verdier, crimson, very large and fine.

Madame Moreau, rose, edged with white, deeper in the centre.

Madame Wm. Paul, bright rose, free-flowering.

Mousseline, white, sometimes slightly tinted in opening, large and full, and thoroughly perpetual.

Perpetual White, white, blooming in clusters, very mossy.

Salet, very bright pink, flowering freely in autumn.

Souperet et Notting, flowers very large and full, of the most perfect form, fine bright rose, foliage large, equal to the *Provence* or *Cabbage Rose*.

BANKSIAN ROSES (R. BANKSIÆ).

The true Banksian Rose is a non-prickly Chinese climber, with stems often 20–30 ft. long, in favourable places. The leaves consist of 3–5 shiny, oblong, lance-shaped serrated leaflets, very hairy at the base of the middle nerve, and with ciliated stipules. Flowers in June, white, very double, nodding.

It was named by Robert Brown in honour of Lady Banks—whose husband Sir Joseph was a great patron of botany and horticulture. The first plant was introduced in 1807, and what is asserted to be the identical one is still growing at Spring Grove House, Isleworth, where

the residence of Sir Joseph Banks stood until a few years ago when it was replaced by a modern mansion.

Culture and Propagation.—The Banksian Roses require the shelter of a warm wall, and a dry border with rich soil to bring them to perfection. They require very little pruning, just removing the later sappy shoots after July. The white (*alba*) and yellow (*lutea*) varieties are grown, and should be on their own roots. A mulching with manure in hard winters will prevent them being killed.

DAMASK ROSES (R. DAMASCENA). These roses are supposed to be of Syrian origin, and were first introduced from the Holy Land by a Comte de Brie when returning from the Crusades in 1270.

The shoots and leaves of the Damask Roses are of a distinct light green. The plants are perfectly hardy, with numerous fragrant flowers, and require very little pruning. For general culture and propagation see p. 382.

The varieties usually met with are *La ville de Bruxelles*, light rose, with a blush margin; *Leda* or *Painted*, blush, edged with lake; *Madame Hardy*, large, beautiful white; *Madame Staltz*, pale yellow, cupped; *Madame Zoetmans*, creamy white shaded buff; and *York and Lancaster* (true), red and white, sometimes striped, liable to sport and come self-coloured. Some of the Provence Roses are also called 'York and Lancaster.'

The *Rose du Roi* is a very old Damask Perpetual Rose with bright crimson flowers.

The ALBA ROSES.—Mr. Baker regards *R. alba* as probably a hybrid between *R. canina* and *R. gallica*. At present the garden hybrids form a small but choice group. They thrive under ordinary care, and the following except *Félicité* should be pruned rather closely.

For general culture and propagation see p. 382.

Belle de Ségur, soft rosy flesh, edges blush, beautiful, of medium size, full, form cupped.

Blanche Belgique, white, very floriferous.

Celestial, flesh colour, beautifully tinted with the most delicate pink, of medium size, double, cupped.

Félicité (*Parmentier*), rosy flesh, margin blush, large and full.

Lorna Doone, deep rose.

Madame Audot, glossy flesh, large and full.

Madame Legras, creamy white, large and full.

Maiden's Blush, soft blush, of medium size.

Mrs. Paul, bold white flowers tinted with rose.

MULTIFLORA or POLYANTHA ROSES.—A very pretty and ornamental class of miniature or fairy Roses which have been much improved by the additions made during the last season or two. The plants are very compact in habit, and bear in great profusion pretty small double flowers. They are admirably suited for pot culture as conservatory plants or for edging Rose beds.

The Polyantha Roses have been spoken of very favourably as stocks for other varieties, and may in the future be more extensively used for that purpose.

For general culture and propagation see p. 382.

The following are some of the best known varieties:—

Aglaia (*Yellow Rambler*), bright canary-yellow flowers, produced in pyramidal clusters, very hardy.

Cécile Brunner, blush, shaded pale pink, very free-flowering, one of the best.

Euphrosyne (*Pink Rambler*), buds carmine, changing to pure rose; a cluster Rose.

Gloire de Polyantha, a miniature flower, deep rose, with a white base to the tiny petals.

Golden Fairy, bright fawn, tinted white.

Jeanne Ferron, pink, lighter colour as the flower expands, reflexed, a good climber.

Ma Paquerette, pure white.

Mignonette, rosy pink, a beautiful miniature Rose.

Red Pet, rich crimson, very small, very free-flowering.

The Pet, delicate pink, changing to white.

Turner's Crimson Rambler, a fine introduction from Japan, producing large clusters of brightest crimson flowers. The plant is of very vigorous growth, producing shoots 8-10 ft. long in one season. A grand variety for climbing or pegging, very hardy, free-flowering, and a continuous bloomer. It succeeds on the

Manetti stock or on its own roots, better than when budded on the Dog Rose. Cuttings of the ripened shoots will also root freely and make good plants.

AYRSHIRE ROSES (*R. ARVENSIS* or *REPENS*, VAR.).—The Ayrshire Roses are usually considered to be descended from the common Field Rose (*R. arvensis* or *repens*). From their hardiness, and rapid growth, they are admirably adapted for planting in rough situations where choicer kinds will not thrive, and for climbing over banks, trees, pillars, buildings &c. When grafted or budded on tall stems they also make excellent weeping Roses.

They are of the easiest cultivation in ordinary good and well-drained garden soil, and will respond to the best of treatment as given to the Tea-Scented and Hybrid Perpetual varieties. They require little or no pruning, so long as the shoots are not allowed to get entangled and overcrowded. The following are some of the best varieties. For general culture and propagation see p. 382.

Alice Gray, white, delicately edged with pink.

Bennett's Seedling, a lovely double white-flowered variety.

Dundee Rambler, white, with pink edge.

Princess Victoria, pale flesh.

Queen of the Belgians, creamy white, double.

Rivers' Ayrshire Queen, reddish-purple.

Ruga, pale flesh, very fragrant.

Splendens, pale flesh, buds crimson.

Virginian Rambler, a very free-flowering variety with beautiful pinky-white blossoms.

EVERGREEN ROSES (*R. SEMPERVIRENS*).—These are valuable climbing Roses, blooming in large clusters of ten to fifty blooms each, and holding their dark green shining foliage through a great part of winter; they are free growers and quite hardy. Like the *Ayrshire*, they form beautiful weeping Roses. In pruning the head should be well thinned out, a few of the more pendant shoots being left their whole length; these will flower to their very points. For general culture and propagation see p. 382.

Donna Maria, pure white, small and double.

Félicité Perpetue, creamy white, beautiful, small and full, one of the finest.

Flora, rosy flesh, full. It has pretty

red shoots and glossy green leaves which stand smoky atmosphere well.

Leopoldine d'Orléans, white, tipped with red, small and double.

Myriantes Renoncule, bluish edged with rose, small and double. A beautiful variety.

Princess Marie, a double pink-flowered variety which retains its leaves somewhat longer than the others.

FRENCH, GALLICA, or GARDEN ROSES (*R. GALLICA*).—These Roses grow anywhere, but become of greatly increased beauty under good cultivation. They may be distinguished by their stiff erect growth. As standards they form compact heads, which display the flowers to great advantage. The flowers are remarkable for their brilliant and richly varied hues, fulness, regularity, and a delicious fragrance. They require moderately close pruning. The striped varieties of this section (*Rosa Mundi*, &c.) are often called *York and Lancaster*.

For general culture and propagation see p. 382.

Blanchefleur, white slightly tinted with flesh.

Boule de Nanteuil, crimson-purple. centre sometimes fiery.

Cynthia, pale rose, light margin, beautiful, large.

D'Aguesseau, crimson richly shaded with purple, large and full.

Duchess of Buccleuch, dark rose, margin bluish, beautiful.

Kean, rich velvety purple, centre scarlet.

Éillet Parfait, pure white with broad stripes of rosy crimson, beautiful, very double.

Ohl, dark crimson and scarlet shaded, large.

Perles des Panachées, white, striped with rose.

Rosa Mundi, red striped with white, sometimes all red; large and semi-double.

Village Maid, white striped with rose and purple, large and full, of cupped form.

HYBRID SWEET BRIARS.—These lovely Hybrids raised by Lord Penzance are crosses between the Common Sweet Briar and various old-fashioned Garden Roses; the flowers are single or semi-double, and vary in colour from pale yellow to crimson. The plants are very vigorous and perfectly hardy and the

foliage of all of them is as sweetly scented as the Common Sweet Briar. They form a distinct break from any class of Rose yet in commerce. They are excellent plants for making hedges, and by pegging the shoots down as described above at p. 384 these Sweet Briars form one of the most effective sights in the garden, especially when they have become well established. Not only are their flowers lovely in every way, but the sweet fragrance of the plants is a character of the highest importance.

For general culture and propagation see p. 382.

Amy Robsart, a lovely deep rose, an abundant bloomer, robust and free.

Anne of Geierstein, dark crimson, followed by an abundance of pretty clustered bunches of hips. It is a strong grower and would make an excellent hedge.

Brenda, soft blush or peach, handsome in colour and shade.

Catherine Seton, a very pleasing tint of soft rosy pink, the bright golden anthers being very prominent, very free-flowering, perpetual, and a good Autumnal Rose.

Edith Bellenden, pale rose, flowering profusely in clusters at the ends of the shoots, which are long and pendulous.

Flora McIvor, pure white, blushed with rose, perfect for cutting.

Green Mantle, bright rich pink, with a band of white encircling the anthers, which, with their background of white, have a very pretty effect. This variety, too, is very free-flowering, and a good Autumnal Rose.

Jeannie Deans, semi-double, very large, scarlet-crimson, flowering freely in clusters, foliage of a deep, healthy-looking green, and very strong growing.

Julia Mannering, soft pearly or porcelain pink, the prettiest of all the pink varieties, very free-flowering, thoroughly perpetual, with flower and foliage deliciously scented.

Lady Penzance, copper-tinted yellow. This is a grand Sweet Briar and probably the finest for giving beautiful effects.

Lord Penzance, fawn colour.

Lucy Ashton, white, pink edges.

Lucy Bertram, a fine deep crimson, the richest colour of all; the centre is pure white, which shows off the bright yellow anthers to good advantage; branching habit, free-flowering, a good Autumnal Rose.

Meg Merrilies, crimson.

Mini, large pure white, opening with a tint of palest blush, bushy habit, foliage like a Scotch Briar.

Rose Bradwardine, clear rose.

HYBRIDS OF CHINESE, BOURBON, and NOISETTE ROSES (R. GALLICA).—The Roses in this section are Hybrids between the Gallica, Centifolia, &c., and the Chinese, Noisette, and Bourbon. Most of them grow to perfection as Wall or Pillar Roses. In pruning they should be well thinned out, and the shoots left for flowering shortened but little. The moderate growers, like *Comtesse Lacépède* and *Souvenir de Pierre Dupuy*, require closer pruning. These Hybrids are still valuable, frequently concentrating in the same flower perfection in the desired points—form, fulness, and size; and further, many of them are brilliant in colour. For general culture and propagation see p. 382.

The following are some of the best varieties grown:—

Blairii No. 2, blush-pink, fine, very large and double.

Brennus or *Brutus*, deep carmine, superb, very large and full.

Charles Lawson, vivid rose shaded, large and full; one of the best.

Charles Duval, deep pink, large and full, cupped.

Chenedole, light vivid crimson, colour exquisite, very large and double; a fine pillar Rose.

Comtesse Lacépède, silvery blush, sometimes rosy flesh, large, full, cupped.

Coupe d'Hébé, rich deep pink, large and very double; one of the best.

Fulgens, deep crimson; a good climbing Rose.

General Jacqueminot, deep purple, shaded with crimson.

Juno, pale rose, blush edges, very large and full.

Madame Barriot, light rose, shaded.

Madame Plantier, pure white, free bloomer, beautiful, full; the finest of all pure white Roses for massing.

Madeline, white, usually margined with crimson.

Paul Perras, beautiful pale rose, fine, very large and full.

Paul Ricaut, bright rosy crimson, large and full; one of the best.

Paul Verdier, magnificent bright rose, large, full, and perfectly imbricated; good Rose.

Souvenir de Pierre Dupuy, deep velvety red, very large and double; fine.

Vivid, vivid crimson, very showy; a fine pillar or climbing Rose.

William Jesse, purplish-crimson, tinged with lilac, large and double.

Climbing Roses

Although the best Climbing Roses have already been mentioned in the sections to which they belong, it may be convenient to have a separate list of them for ready reference. With the exception of the Banksian Roses (see p. 396) most of the Climbing Roses are easily grown, and their general culture and propagation are as detailed at p. 382. Their great value for garden purposes consists in the many ways they may be utilised for the ornamentation of parts of the garden where no other plant would be so effective or so appropriate, or give such a wealth of blossom and variety of colour. Old trees, old buildings, walls, sheds, arbours, pergolas, arches, trellises, banks, and almost any place where long rambling branches will go, are suitable places for Climbing Roses, provided they are judiciously planted, and not overcrowded.

The following is a list of some of the best Climbing Roses:—

HYBRID PERPETUAL CLIMBERS

Climbing Duchess of Norfolk (p. 386).

Climbing Etienne Levet (p. 386).

Climbing Jules Margottin (p. 386).

Climbing Star of Waltham (p. 387).

Climbing Victor Verdier (p. 387).

Paul's Carmine Pillar (p. 388).

Climbing Edouard Morren (p. 388).

Climbing La France (p. 388).

Climbing Marie Cointet (p. 388).

Climbing Queen of Queens (p. 388).

Princess Louise Victoria (p. 389).

TEA-SCENTED CLIMBERS

Climbing Kaiserin Augusta Victoria (p. 393).

Climbing Perle des Jardins (p. 391).

Climbing Devoniensis (p. 391).

Climbing Niphetos (p. 391).

Cheshunt Hybrid (p. 392).

Gloire de Dijon (p. 391).

Longworth Rambler (p. 392).

Reine Marie Henriette (p. 392).

NOISSETTE CLIMBERS AND THEIR HYBRIDS

Aimée Vibert (p. 393).

Alister Stella Gray (p. 393).

Blairi No. 1 (p. 394).

Comtesse de Galard Bearn (p. 393).

Jaune Desprez (p. 393).

Rêve d'or (p. 394).

Vivid (p. 400).

Wm. Allen Richardson (p. 394).

OTHER CLIMBING ROSES

Ayrshire, see varieties (p. 398).

Banksian varieties (p. 396).

Cramoisie supérieure (monthly), (p. 394).

Evergreen varieties (p. 398).

Multiflora or *Polyantha varieties* (p. 397).

Musk Roses (*R. moschata*) (p. 403).

R. setigera (p. 404).

R. wichuriana (p. 405).

WILD ROSES.—Besides the florist's Rose, there are several beautiful natural species which deserve a place in the garden. Of course one of the greatest differences between the two groups is that the flowers of the wild species are usually single, and have the general characters as described at p. 382. In the garden forms the numerous stamens have been transformed into petals, hence the 'doubling.'

Culture and Propagation.—They thrive in good soil, but it is not necessary to take the same amount of trouble over pruning them as with Hybrid Perpetuals and such like. A thinning out of the branches and dead wood here and there is sufficient, and very little shortening back of the shoots is required during the year. They are not nearly so much subject to disease and insect pests as the garden varieties, and the fact that they vary a good deal in habit—from dwarf sturdy bushes to long-branched climbers—enables one to use them in many ways.

They may be increased by seeds, but owing to the ease with which some of them hybridise, the progeny may not come quite true. They are probably best obtained by layering the branches, and thus getting them on their own roots. The following is a selection:—

R. acicularis.—A native of North temperate regions, with very prickly stems and very glaucous leaves, composed of about 7 oval, slightly rugose, serrated leaflets. Flowers in June, pale blush, solitary, fragrant, followed by yellowish-orange obovoid fruits.

Culture &c. as above.

R. alba.—This is of garden origin, and has given rise to the 'Alba' roses (see p. 397). It grows 4-7 ft. high, with straight or falcate prickles, oblong, glaucous, serrated leaflets, and very fragrant, white or delicate blush blooms in June and July. Fruit scarlet or blood-red, oblong, unarmed. There is a sweet-scented variety called *suaveolens*.

Culture &c. as above.

R. alpina.—A native of Europe, about 3 ft. high, with prickles on the young stems. Leaflets 5-11, ovate or obovate, sharply serrated. Flowers in June, pink or rose. Fruit orange-red, ovate or roundish, drooping. The Boursalt Roses (see p. 395) originated from this.

Culture &c. as above.

R. altaica.—A beautiful species 3-4 ft. high with white flowers 2-3 in. across, produced during May and June. The bundle of bright yellow stamens in the centre is in good contrast to the roundish wedge-shaped petals.

Culture &c. as above.

R. beggeriana.—A pretty shrub 4-6 ft. high, native of Central Asia. The leaves are composed of 3-4 pairs of small elliptic serrate leaflets, and furnish slender branches having only a few recurved spines but no prickles. The small white flowers are borne in rather large corymbs, and continue to appear throughout the summer months. They are afterwards succeeded by fruits not much larger than a pea, at first orange-red, but turning deep purple-black when ripe.

Culture &c. as above.

R. bracteata (*Marcartney Rose*).—An erect woolly Chinese plant about 2 ft. high, armed with strong, recurved, often twin prickles. Leaflets 5-9, obovate, slightly serrated, smooth, shining. Flowers in July, large, white, solitary and sweetly scented. The variety *alba simplex* has a conspicuous mass of yellow stamens in the centre, while *Marie Leonida* has large double white flowers, creamy blush in the centre.

Culture &c. as above. The Macartney Roses, though somewhat tender, are very pretty and distinct and almost evergreen. They repay for a little care and should be grown in warm sunny spots on a south wall or fence.

R. canina (*Dog Rose*).—A handsome British Rose forming large bushes in our

thickets and hedges, and having arching prickly branches with smooth or slightly hairy and sharply toothed leaflets. The beautiful cup-shaped blossoms, 2-3 in. across, appear in June and July, and vary from pure white to deep rose in colour. There are many varieties of the Dog Rose.

Culture &c. as above. Excellent for hedges, and for stocks.

R. carolina (*Carolina Swamp Rose*).—A pretty N. American species 4-7 ft. high, armed with stout hooked prickles. Leaflets 5-9, elliptical. Flowers from June to September, pink, in corymbs of a dozen or more. Fruit somewhat bristly.

Culture &c. as above.

R. centifolia (*Provence or Cabbage Rose*).—A pretty Rose 3-6 ft. high, native of the East, with prickly branches and leaves composed of 5-7 ovate serrate leaflets slightly hairy on the under surface. The large sweet-scented rose-purple flowers appear in June and July and are succeeded by fragrant top-shaped 'hips.' The variety *muscosa* with rose or white flowers is the origin of the Moss Rose (see p. 395).

Culture &c. as above.

R. damascena (*Damask Rose*).—This, the parent of many garden forms (see p. 397), is a native of the East, and makes bushes 2-4 ft. high. It has very prickly stems and leaves composed of 5-7 ovate stiffish leaflets. The large sweet-scented white or rosy flowers are borne in trusses in June and July, and have clammy hairy calyces.

Culture &c. as above.

R. ferruginea (*R. rubrifolia*).—A European species like the 'British Dog Rose.' It has deep red or purple stems about 6 ft. high, armed with small short hooked prickles. Leaflets ovate, toothed, very glaucous, and brightly tinged with red, wrinkled. Flowers in August, deep red, small. Fruit purple-red with a soft flesh.

Culture &c. as above.

R. gallica.—A native of Southern Europe and Western Asia 2-3 ft. high, with prickly stems and 5-7 ovate or lance-shaped leathery leaflets composing the leaves. The flowers, which vary from red to crimson and are double or semi-double, appear in June and July.

Culture &c. as above. Several garden Roses have originated from this species.

R. gigantea.—A magnificent Indian climbing Rose with stems often reaching a length of 40 ft. Flowers pure white, 6 in. or more across, golden-yellow in bud. This species has not yet been flowered in the British Islands, but has done so in the south of France. It is hardy in the milder parts of the kingdom, and it may some day astonish its possessors by showing its beautiful blossoms.

Culture &c. as above, p. 382.

R. Godefroyæ.—A compact, smooth-stemmed bush, native of Persia, with shining dark green leaves, having 5-7 leaflets. Flowers in summer, large, with numerous white petals.

Culture &c. as above, p. 382.

R. Hardi.—This is supposed to be a hybrid between the simple-leaved and yellow-flowered *R. simplicifolia* and the white-flowered *R. involucrata* which has compound leaves. It is a rather pretty Rose with leaves composed of 5-7 serrate leaflets, the terminal one of which is much larger than the others. The flowers resemble those of a *Cistus* (see p. 223), being 2 in. across and soft yellow in colour with a crimson blotch at the base of each notched petal. It grows and flowers more freely than *R. simplicifolia*.

Culture &c. as above, p. 382.

R. hemisphærica (*R. sulphurea*).—A beautiful species about 3 ft. high, native of the East, with somewhat spiny stalks. Leaves composed of 5-7 obovate toothed leaflets, paler beneath, and downy on the nerves. Flowers in summer, soft yellow.

Culture &c. as above, p. 382.

R. hispida (*R. lutescens*).—A species closely allied to the Scotch or Burnet Rose, but of uncertain origin. It grows 5-6 ft. high, with prickly branches and leaves having 7 oval, sharply toothed leaflets. Flowers in June, white tinged with soft yellow.

Culture &c. as above, p. 382.

R. indica (*Blush, Common China, or Monthly Rose*).—A stout, brown-prickled species, probably native of China, notwithstanding its name. Leaflets 3-5, shining, elliptic acuminate, crenate serrate, dark above, glaucous beneath. Flowers at all seasons (hence the name Monthly Rose), usually semi-double, red, numerous. Fruit scarlet, obovate.

This species has played an important part in the production of the China or Bengal Roses (see p. 394), the Bourbon (p. 394), and the Tea Roses (p. 389).

The 'Green Rose' called *monstrosa* is a variety of *indica*.

Culture &c. as above, p. 382.

R. involucrata (*R. Lyelli*).—A pretty Indian Rose about 3 ft. high, with leaves 3-4 in. long, and composed of 3 or 4 pairs of elliptic oblong finely serrate leaflets. The white sweet-scented flowers, each 2-3 in. across, are produced in July and August either singly or in small clusters, and are succeeded by round, woolly-stemmed fruits.

Culture &c. as above, p. 382.

R. lævigata (*R. sinica*).—*Cherokee Rose*.—A Chinese Rose, now naturalised in the United States and West Indies. It has long trailing stems, the branches armed with stout, curved prickles and evergreen, usually 3-foliolate, smooth and shining leaves, hairy on the midribs. Flowers in June, white, large, solitary. Fruit orange-red, warty. Rather tender.

Culture &c. as above, p. 382.

R. lucida.—A beautiful N. American Rose 1-2 ft. high, armed with bristly prickles. Leaflets shining green, 5-9 elliptic or oblong lance-shaped, sharply serrated. Flowers from May to July, red, 1-3 on a stalk. The variety *flore pleno* has charming double flowers. It is known as 'Rose Button.' The fruits of this Rose are deep red, about the size of a Hazel-nut, and look handsome among the autumn-tinted foliage.

Culture &c. as above.

R. lutea (*R. Eglanteria*).—*Austrian Briar*.—An Eastern species about 3 ft. high, with straight prickles. Leaves 1½-3 in. long; leaflets 2-4 pairs, elliptic ovate or roundish, deeply toothed. Flowers in June 2-2½ in. across. The variety *punicea* has flowers scarlet inside, yellow outside, and purple stigmas. There is also a form (*flore pleno*) with double flowers which looks particularly attractive when laden with blossom.

The best known forms are the Austrian Yellow and Austrian Copper Briars with beautiful single flowers. *Harrisoni* and the *Persian Yellow* are also fine golden-yellow. The latter has leaves scented like Sweet Briar. When pruning the head should be well thinned, but the shoots

intended for flowering should be allowed to remain long.

Culture &c. as above, p. 382.

R. macrophylla.—A distinct prickly Rose, about 6 ft. high, native of Thibet. Leaves 2-8 in. long, with elliptic ovate, finely toothed leaves usually downy beneath. Flowers in summer, pink, 1-3½ in. across, with broadly obovate petals. Fruit sometimes 2 in. long.

Culture &c. as above, p. 382.

R. microphylla.—A sturdy Chinese shrub, 2-4 ft. high, with only slightly prickly stems and small ovate leaflets 9-15 in number. Flowers from August to October, rather large, delicate rose, very fragrant. Fruits large, globular, prickly, green or yellowish when ripe, exhaling a Pineapple odour.

There is a double-flowered variety (*flore pleno*) which has been much longer in cultivation than the type.

Culture &c. as above, p. 382.

R. minutifolia.—A compact-growing Californian Rose, the stems of which are armed with numerous straight spines, and clothed with very small leaves having 5-7 deeply toothed leaflets. The small solitary pink or white flowers are produced on short spurs along the branches.

Culture &c. as above, p. 382.

R. mollis.—A British species forming a large bush with erect or arching prickly stems and very hairy leaves. The red flowers appear in June and July and are succeeded by roundish or top-shaped fruits usually densely covered with prickles.

Culture &c. as above, p. 382.

R. moschata (*R. Brunoni*).—*Musk Rose.*—A native of S. Europe to India, with climbing stems 20 ft. or more in length. Leaves 2-6 in. long, with 2-4 pairs of ovate or ovate-lance-shaped acute leaflets, sharply serrated, somewhat downy beneath. Flowers in July and August, about 2 in. across, yellowish-white, very numerous, in compound corymbs and delicately fragrant. This is one of the reputed parents of the Noisette Roses (see p. 393), and is excellent for cutting purposes. In the variety *nivea* the blossoms are pure white sometimes flushed with pink.

Musk Roses are of rapid growth, best adapted for climbers; they require little pruning. The flowers have a peculiar

Musk-like scent as a point of distinction, but it requires a still, moist atmosphere to be readily appreciable.

The following are good varieties:—

Eliza Werry, nankeen-yellow, changing to white.

Fringed, white, petals serrated; cupped.

Princesse de Nassau, yellowish straw, cupped, very sweet.

Rivers, pink shaded with buff.

R. multiflora (*R. polyantha*).—A native of China and Japan, with stems about 12 ft. long, having scattered slender prickles. Leaflets ovate lance-shaped, slightly wrinkled. Flowers in June, white, pink, or purple, in corymbs. Fruits bright red. *Carnea* is a double pink-flowered form; *flore pleno* differs from the type only in its double flowers, and *platyphylla* has broader leaflets and purple double flowers.

The 'Dawson Rose' is a hybrid between *R. multiflora* and the crimson Hybrid Perpetual 'General Jacqueminot.' It has gracefully arching sprays of semi-double pink and white blossoms, 12-20 in a cluster, during June and July. It is an elegant Rose for massing in beds on grass-land.

Culture &c. as above, p. 382.

R. nutkana.—A distinct species from N.W. America, having rather broad smooth or downy leaves, at the base of which there are usually some broad flat spines, and occasionally scattered prickles. The flowers are borne in loose corymbs, and are succeeded by round bright scarlet fruits about ½ in. in diameter.

Culture &c. as above, p. 382.

R. pisocarpa (*R. pisiformis*).—An interesting Californian Rose having smooth reddish stems armed with straight prickles. It makes a long straggling freely branched bush clothed with rather small leaves of 5 leaflets. The bright pink flowers, each about an inch across, appear in twos and threes in summer, and are followed by roundish red fruits about ½ in. through, which look very attractive.

Culture &c. as above, p. 382.

R. Pissardi.—A beautiful species 15-20 ft. high, native of the Caspian shores. The spiny glaucous branches are spreading or bent downwards, and are furnished with deep green leaves. The sweet-scented white or blush-white blossoms

are semi-double; they appear late in summer and are produced in great abundance in upright corymbs, being succeeded by deep red fruits.

Culture &c. as above, p. 382.

R. pomifera (*Apple Rose*).—This is an old-fashioned British Rose with glaucous foliage. The flowers are single, blush-coloured, and succeeded by handsome scarlet fruits 1–2 in. long, apple or pear-shaped, and covered with bristles.

Culture &c. as above, p. 382.

R. repens (*R. arvensis*).—A rambling British and European species, 2–8 ft. high, from which the Ayrshire Roses have been developed. The trailing purplish glaucous stems are armed with stout strongly hooked prickles, and clothed with smooth leaflets, glaucous beneath. Flowers in summer, 1–6 in a truss, rarely solitary, white, with a yellow blotch at the base of each petal. Calyx purple. There are several forms, and also one with double flowers.

Culture &c. as above, p. 382.

R. rubiginosa (*Eglantine*; *Sweet Briar*).—A delightfully fragrant pretty native Wild Rose about 5 ft. high. Leaflets glabrous above, downy beneath. Flowers in June, pink, 1–3 on a stem. It is an excellent hedge plant, and not a few places in England boast a 'Sweet Briar Lane.'

Culture &c. as above, p. 382.

R. rugosa (*Japanese* or *Ramanas Rose*).—A distinct-looking and handsome bush about 4 ft. high, native of Japan, densely armed with straight prickles. Leaflets 5–9, ovate, much wrinkled, serrated, blunt. Flowers in June, red, large, solitary. Fruit as large as a thrush egg, varying from orange-red to deep red, very handsome, with an edible pulp. There are several forms, the best of which are *alba*, with pure white flowers; *plena*, a double crimson; *Coubert's Double White* with beautiful satiny white flowers; *fimbriata*, white Picotee edged petals; and *Mdme. Georges Bruant*, white, semi-double.

R. rugosa has been crossed with some of the Bengal Roses, and has produced a hybrid called *calocarpa*, and it has also been crossed with the well-known hybrid perpetual *General Jacqueminot*. There seems to be a great future before this species in the hands of the hybridist.

Culture &c. as above, p. 382.

R. sericea.—An Indian species, with smooth or slightly prickly stems which, when young, are sometimes red. Leaves 1–3 in. long, with 7–9 oblong, blunt, sharply toothed leaflets, silky beneath. Flowers in May, white, rarely pink or pale yellow, often having only 4 instead of 5 petals. The variety *pteracantha* is distinguished by having winged, thin spines, sometimes 1½ in. wide at the base.

Culture &c. as above, p. 382.

R. setigera (*Climbing* or *Prairie Rose*).—A pretty N. American climber, stems 10–20 ft., armed with stout straightish prickles. Leaflets 3–5, ovate acute, sharply serrated, smooth or downy beneath. Flowers in July, deep rose, changing to white, corymbose.

Culture &c. as above, p. 382.

R. simplicifolia (*R. berberifolia*).—An Asiatic species 2–3 ft. high, remarkable for its small, simple, Barberry-like, downy leaves and slender downy branches. Flowers in June, sweet-scented, solitary, deep yellow, with a dark crimson spot at the base of each petal.

Culture &c. as above, p. 382.

R. spinosissima (*S. pimpinellifolia*). *Burnet* or *Scotch Rose*.—A pretty British Rose, 1–4 ft. high, with very unequal crowded prickles. Leaflets 7–9, rather broad, serrated. Flowers in May and June, less than 2 in. across, white or pink, 1 or more on a stalk. The variety *altaica* is a taller growing plant with broader leaves and fine flowers.

The varieties belonging to this group all form compact bushes, flowering abundantly early in the season before most other Roses. They are not adapted for growing as standards. The flowers are small and globular, many of them as they hang on the bush looking like little balls. Their colours are yellow, white, and various shades of pink, rose, and crimson.

Culture and Propagation.—If carefully planted at first Scotch Roses will require but little attention. They are proof against frost and snow, and are rarely if ever subject to mildew or green fly.

Speaking generally they are best grown in beds by themselves, but are also suitable for covering rough banks and transforming them into a charming picture. In poor soils, they may be given a good mulching of rotted manure every autumn. Only the bright clear-coloured

varieties are worth growing. For general culture &c. see p. 382.

What are known as Perpetual Scotch Roses are represented by one called *Stanwell Perpetual*, which has rosy blush flowers, often with a pink centre.

R. tomentosa.—A British and European species with arching prickly stems 6 ft. or more high. Leaves 4–5 in. long, with doubly serrate leaflets, greyish above, and more so beneath. Flowers in summer, bright rosy pink, sometimes white, about 2 in. across. There are many varieties of this species, among which may be mentioned *woodsiana*, with fine deep rose-purple flowers.

Culture &c. as above, p. 382.

Tribe VII. POMEÆ.—Trees and shrubs often with simple leaves. Calyx-tube adnate to the ovary (or carpels sunk in the top of the fleshy flower-stalk). Stamens numerous. Fruit a pome or drupe.

PYRUS (APPLE, PEAR, QUINCE, MEDLAR, CRAB &c.).—A genus with 35–40 species of ornamental deciduous trees and shrubs, with alternate, simple or pinnate, stalked and often serrate leaves. Flowers usually in terminal cymes. Calyx tube urn-shaped or rarely top-like, 5-lobed. Petals 5, roundish, shortly clawed. Fruit fleshy, ovoid, globose or pear-shaped.

Besides the cultivated Apple, Pear, Medlar, there are many other fine flowering trees in this genus, such as the Japanese Quince, *Pyrus (Cydonia) japonica*, and the Mountain Ash or Rowan Tree, the latter being also remarkable for its masses of orange-red or scarlet fruits. Some of the finest species for the decoration of parks, gardens, pleasure grounds, &c. are described below.

Culture and Propagation.—The trees all grow well in fairly good garden soil, and many of them might be more extensively used on large lawns than is now the case. They are increased by seeds, layers, cuttings, budding and grafting, in the same way as Apples (p. 1042) and Pears (p. 1059).

P. americana (Sorbus americana).—*American Mountain Ash.*—A beautiful N. American tree, with oddly pinnate leaves, composed of 13–15 lance-shaped tapering, serrated leaflets. Flowers in June, white, followed by clusters of bright red berries about the size of peas.

Culture &c. as above.

P. angustifolia.—A handsome North American tree about 20 ft. high, closely

R. wichuriana.—A beautiful Japanese Rose, with prostrate stems about 12 ft. long, and shining green leaves. Flowers late in summer, pure white, 1½–2 in. across, slightly raised above the creeping stems.

Lucida is a pretty hybrid variety with glaucous, reddish foliage, and bright red flowers.

Culture &c. as above, p. 382.

R. xanthina (R. Ecœ).—A charming dwarf, prickly species, suitable for the rockery, native of Afghanistan. Leaves with 5–9 small leaflets. Flowers in summer, golden-yellow, less than 1 in. across.

Culture &c. as above, p. 382.

related to *P. coronaria*, with simple oblong or lance-shaped leaves, usually toothed at the edges and smooth to the touch. The beautiful rose-coloured flowers appear in April and are deliciously scented. There is a double-flowered variety (*flore pleno*) apparently superior in every way to the single-flowered type. It is perfectly hardy and grows in any good garden soil, and bears a wealth of fragrant double blossoms.

Culture &c. as above.

P. arbutifolia (P. floribunda).—*Chokeberry.*—A pretty N. American shrub 2–10 ft. high. Leaves simple, oblong or obovate, finely serrate, woolly beneath. Flowers in May and June, white, sometimes purple-tinted. Fruit red or purple, pear-shaped or globular. The variety *melanocarpa (P. grandifolia)* has larger leaves, and dark purple fruits.

Culture &c. as above.

P. Aria (White Beam Tree).—A British tree sometimes attaining a height of 40 ft. Leaves simple or pinnatifid, 2–6 in. long, smooth above, plaited, coarsely and irregularly toothed, deeply lobed, cottony beneath. Flowers in May and June, white, ½ in. across, in loose corymbs. Fruit red or scarlet, dotted, about ½ in. in diameter. There are two or three varieties varying somewhat in the leaves and the colour of the fruits.

Culture &c. as above.

P. Aucuparia (Mountain Ash; Rowan Tree).—A well-known British tree 10–30 ft. high, leaves 5–8 in. long, with 6–8 pairs

of linear oblong, serrate leaflets. Flowers about Whitsuntide, creamy white, in dense cymes 4-6 in. long. Fruit scarlet or orange-red. There are several forms, among them being *fastigiata*, more erect in growth; *fructu-luteo*, with yellow berries; *pendula*, with weeping branches; and *variegata*, with variegated leaves, not well marked.

Culture &c. as above.

P. baccata (*Siberian Cherry Crab*).—A handsome Siberian tree 15-20 ft. high, with ovate acute serrated leaves on long stalks. Flowers in April and May, white, crowded. Fruit yellow tinged with red, about the size and shape of a Cherry. A very variable species, chiefly recognised by its deciduous calyx lobes.

Culture &c. as above.

P. Chamæmespilus (*Cratægus Chamæmespilus*; *Sorbus Chamæmespilus*).—*False Quince*.—A shrub 5-6 ft. high, native of the mountainous parts of Europe. Leaves ovate, serrate, smooth, downy when young. Flowers in May and June, reddish. Fruit red, round. The variety *Hosti* has broadly elliptic, often lobed leaves, and rosy pink flowers in large terminal corymbs.

Culture &c. as above.

P. communis (*Wild Pear*).—A native tree 20-40 ft. high, with oblong-ovate acute, bluntly serrated leaves, more or less downy when young. Flowers in April and May, white, 1-1½ in. across. Fruit 1-2 in. long, pear-shaped. There are several forms, such as *cotinifolia*, *fascicularis*, *flore pleno*, *pendula*, &c.

Culture &c. as above; see also Pear, p. 1059.

P. coronaria (*Sweet-scented Crab*).—A pretty N. American tree 20 ft. high. Leaves simple, ovate, somewhat cordate, deeply toothed or lobed. Flowers in May, rosy, large, fragrant. Fruit greenish, fragrant. The variety *flore pleno* is far superior to the single-flowered type. Its blossoms are rosy white, and over 2 in. across with 2 or 3 rows of petals. The blossoms are borne in large clusters, and render this one of the finest flowering trees at the end of May.

Culture &c. as above.

P. floribunda.—A very ornamental Japanese Crab, with slender shoots and small, oblong lance-shaped, toothed leaves. Flowers in May, rich rosy red, freely

produced. Fruit long-stalked, very small, roundish. There are numerous varieties, including *atrosanguinea*, with deep red flowers; *Elise Rathe*, and *pendula*, drooping habit; *Toringo* (the *Toringo Crab*), a variety with sharply cut, usually 3-lobed, downy leaves, and others; its sub-variety *Ringo* is a free-flowering, ornamental shrub with deeper-lobed leaves.

Flore pleno (also known as *Malus halleana* and *M. Parkmanni*) is a beautiful tree 10-13 ft. high, with more or less double flowers of a soft rosy tint and gracefully borne on long slender red-brown stalks.

Culture &c. as above.

P. germanica (*Mespilus germanica*).—*Common Medlar*.—A free-flowering British tree 10-20 ft. high, with obovate or lance-shaped serrated leaves, somewhat downy beneath. Flowers in May and June, white, over an inch across. Fruit about 1 in. in diameter, roundish, with a depressed area at the top, and persistent calyx lobes. There are several forms.

Culture &c. as above. See also Medlar, p. 1085.

P. japonica (*Cydonia japonica*).—*Japanese Quince*.—A handsome Japanese shrub 5-8 ft. high, with smooth, oval, crenate serrate leaves. Flowers brilliant scarlet, produced in great profusion soon after Christmas, and while the plant is in a leafless state. Fruit green, fragrant, but not edible. There are several forms, usually distinguished by the brilliancy or dulness of the flowers. The white-flowered form, *nivalis*, is very pretty. There is also a semi-double variety.

Grown as a bush or against walls, the Japanese Quince always looks effective and brilliant during the duller season of the year, and continues to blossom well into May. Small plants in pots flower freely in cold houses early in the year.

Culture &c. as above. See also Quince, p. 1085.

P. lobata (*Mespilus grandiflora*).—A Caucasian Medlar about 20 ft. high. Leaves oblong elliptic, serrate, nerves beneath, downy. Flowers in May and June, white, about ¾ in. across.

Culture &c. as above. See also Medlar, p. 1085.

P. Malus (*Crab*; *Wild Apple*).—A British tree about 20 ft. high. Leaves 1-2 in. long, oblong, rounded, pointed or

tailed. Flowers in May, pink and white, about $1\frac{1}{2}$ in. across. Fruit yellow, 1 in. in diameter, roundish. There are several varieties, the best of which are *Bertini*, remarkable for its masses of bright-coloured fruits; *cratægina*, with fruits like the Hawthorn; and *sempervirens*, the leaves of which remain long after the others have dropped. The variety *aurea* has yellow leaves with a green patch in the centre.

Culture &c. as above. See also Apple, p. 1042.

P. Maulei (*Cydonia Maulei*).—A lovely Japanese, somewhat spiny, shrub 2–4 ft. high, closely allied to *P. japonica*, than which it is dwarfer, and smaller leaved. Flowers in April, bright orange-red, numerous, followed by very fragrant orange-yellow fruits $1\frac{1}{2}$ –2 in. in diameter, which are excellent as a preserve.

Culture &c. as above. See also Quince, p. 1085.

P. pinnatifida (*P. fenmica*).—An ornamental tree said to be a true native of the Island of Arran. It has oblong leaves 5–6 in. long, pinnately cut and toothed especially towards the base, the under surface being covered with hoary down. The white sweet-scented flowers are borne in loose corymbose clusters in May and June, and are succeeded by scarlet fruits about $\frac{1}{2}$ in. long, which look remarkably pretty in autumn.

Culture &c. as above, p. 405.

P. prunifolia (*Siberian Crab*).—A Siberian tree 20–30 ft. high. Leaves ovate, pointed, serrate, like those of the Cherry tree. Flowers in April and May, white, like those of the Pear. Fruit yellowish, red on the sunny side, borne in great abundance, and of an agreeable acidulous flavour. There are several varieties of the Siberian Crab including a double-flowered one (*flore pleno*), a drooping one (*pendula*), and a scarlet-fruited one (*fructu coccineo*).

Culture &c. as above. See also Apple, p. 1042.

P. salicifolia.—A beautiful flowering tree 10–30 ft. high, native of Siberia. It has narrow lance-shaped leaves 2–3 in. long, finely toothed on the margins, and more or less hoary on the under surface. The charming pure white flowers, about an inch across, are borne in dense corymbs during the spring months, and their purity

is enhanced by the dark stamens in the centre.

P. sinensis (*Sandy Pear*; *Snow Pear*).—A Chinese tree, with leaves like those of the common Pear, but larger, and almost evergreen, the young ones being rendered very conspicuous in spring by their bronzy-red tint. Flowers in April, white. Fruit Apple-like, warty, and gritty flavoured.

Culture &c. as above, p. 405.

P. Sorbus (*Sorbus domestica*).—A native of Britain 20–60 ft. high. Leaves pinnate; leaflets toothed near the apex, cottony beneath. Flowers in May, creamy white. Fruit red, pear-shaped, about 1 in. long, painfully irritable when unripe, but mellowed and rendered edible by frost.

Culture &c. as above, p. 405.

P. spectabilis.—A beautiful Chinese tree 20–30 ft. high. Leaves oval oblong, serrated, smooth. Flowers in April and May, pale red, large, semi-double when open, in sessile umbels. There is a Japanese variety called *Kaido*, with numerous blush-white flowers, wine-red in centre.

Culture &c. as above, p. 405.

P. Torminalis.—A tree 10–50 ft. high, native of Britain, Europe, and N. Africa. Leaves 2–4 in. long, oblong ovate or cordate, 6–10-lobed, lobes triangular, pointed. Flowers in April and May, white, $\frac{1}{2}$ in. across, very numerous. Fruit pear-shaped, greenish-brown, dotted. The variety *pinnatifida* has more deeply cut leaves. *P. cratægifolia* from N. Italy is closely related, but may be distinguished by the thinner texture of the leaves. The flowers are pure white and very showy.

Culture &c. as above, p. 405.

P. vestita (*P. lanata*; *P. nepalensis*). *Himalayan Beam Tree*.—A fine tree 20–30 ft. high, with large ovate-acute or elliptic leaves, silvery white when young, gradually becoming smooth and shining green. Flowers in April and May, white, in woolly corymbs. Fruit greenish-brown, about the size of a small Cherry.

Culture &c. as above.

P. vulgaris (*Cydonia vulgaris*).—*Common Quince*.—A native of S. Europe, 20 ft. high. Leaves ovate, whitish beneath. Flowers in May and June, white or pale red, large. Fruit more or less pear-shaped, with a peculiar, rather plea-

sant aroma. The variety *lusitanica*, the Portugal Quince, has larger leaves and fruit, and is a good stock for Pears.

Culture &c. as above. See also Quince, p. 1085.

CRATÆGUS (HAWTHORN; WHITE-THORN; MAY; QUICK).—A genus with 65 species of beautiful deciduous trees and shrubs, often spiny. Leaves simple, lobed or pinnately cut. Flowers in terminal corymbose cymes. Calyx tube urn-shaped or bell-shaped, 5-lobed. Petals 5. Stamens many. Fruit ovoid or globose, with hard bony cells or stones.

Culture and Propagation.—All the Hawthorns thrive in any fairly good soil, and the following kinds are all more or less worth growing when space can be found for them, although the white and red May trees are sure to be the first favourites. Most of the kinds are increased by budding or grafting on the common Hawthorn which may be raised from seeds sown either in drills or beds, after the pulp surrounding the bony 'seeds' has been rotted away. It is, however, more satisfactory to obtain well-established young trees from a nursery-man.

C. apiifolia.—A native of the United States 8–10 ft. high. Leaves deltoid, 5–7-cleft, acutely lobed and toothed. Flowers in May and June, white. Fruits deep red, ovoid.

Culture &c. as above.

C. Azarolus.—A tree 15–20 ft. high, native of S. Europe. Leaves downy, trifid, with blunt, coarsely toothed lobes. Flowers in May, white, sweet-scented. Fruit red or yellow, ovoid globose, agreeable when ripe.

Culture &c. as above.

C. Carrierei.—A handsome Thorn of hybrid origin with oblong wedge-shaped serrate leaves and clusters of large white flowers in May, succeeded by large scarlet fruits resembling Cherries in autumn.

Culture &c. as above.

C. coccinea (*Scarlet-fruited Thorn*). A native of the United States, 20–30 ft. high. Leaves roundish-ovate, sharply toothed and cut, smooth. Flowers in May, white. Fruit bright coral-red, ovoid, large. Among the several varieties the best known are *corallina*, *glandulosa*, *indentata*, *macracantha* (with long curved

spines), *maxima*, *minor*, *neapolitana* and *subvillosa*.

Culture &c. as above. In France *C. coccinea* has been found to be a much superior stock to the Common White Thorn for grafting or budding purposes. It might be well to try it in the United Kingdom, especially as it can be quickly raised from seeds.

C. cordata (*C. populifolia*).—*Washington Thorn*.—A native of the United States 6–10 ft. high. Leaves broadly ovate or triangular, mostly truncate or slightly cordate at the base. Flowers in May and June, white. Fruit red, very small, roundish.

Culture &c. as above.

C. crenulata.—A beautiful evergreen Thorn, native of the Himalayas. The somewhat drooping branches are thickly furnished with bright green crenulate leaves. The white flowers appear in May and are succeeded by large clusters of brilliant scarlet haws in autumn and winter.

Culture &c. as above. In unfavoured parts of the kingdom it is safer to grow this species on a south wall, although in the south and west it may be grown as a bush. It requires little or no pruning for several years.

C. Crus-Galli (*C. lucida*).—*Cockspur Thorn*.—A North American tree 10–30 ft. high, remarkable for its very long spines. Flowers in May, white tinged with red. Fruit scarlet, eatable. The variety *linearis* has linear lance-shaped leaves, and few shorter spines; *nana*, ovate lance-shaped leaves; *ovalifolia*, ovate rather hairy leaves, semi-cordate serrate stipules, and white flowers; *prunifolia*, broadly ovate, unequally toothed leaves, white flowers; *pyracanthifolia*, oblong lance-shaped, Willow-like leaves; and *splendens*, with obovate wedge-shaped leaves.

Culture &c. as above.

C. Douglasi.—A native of N.W. America, 10–15 ft. high, with rigid spines. Leaves obovate or oval, doubly serrate, smooth. Flowers in May, white. Fruit dark purple, almost black, small.

Culture &c. as above.

C. flava (*C. caroliniana*; *C. glandulosa*).—A tree 12–20 ft. high, native of the United States. Leaves obovate wedge-shaped, somewhat lobed, crenate-serrate; stipules heart-shaped. Flowers in May,

white, usually solitary. Fruit yellow, Pear-shaped, edible.

Culture &c. as above.

C. florentina.—A native of Florence 20–30 ft. high. Leaves ovate oblong, deeply serrated, downy beneath. Flowers in May, white, ovoid, globose.

Culture &c. as above.

C. heterophylla.—An Eastern tree 10–20 ft. high. Leaves smooth, wedge-shaped-lanceolate, somewhat 3-lobed and cut at the apex. Flowers in May, white.

Culture &c. as above.

C. melanocarpa (*C. Oxyacantha oliveriana*).—A native of Tauria 10–20 ft. high. Leaves usually 3-cleft, serrated towards the apex. Flowers in May and June, white. Fruit black.

Culture &c. as above.

C. nigra (*C. carpatica*).—A tree 10–20 ft. high, native of E. Europe. Leaves lobately sinuated, serrate, glossy green above, downy beneath; stipules oblong, doubly serrate. Flowers in May and June, white. Fruit black.

Culture &c. as above.

C. odoratissima.—A Crimean tree 10–20 ft. high. Leaves deeply cut, downy, with sharp lance-shaped serrated lobes. Flowers in May and June, white, very sweet-scented. Fruit large, roundish, yellow.

Culture &c. as above. This species is closely related to *C. orientalis*.

C. orientalis (*C. sanguinea*).—A native of the Levant 12–20 ft. high; with hoary branches. Leaves 3-lobed, downy beneath; lobes ovate, deeply toothed at the apex. Flowers in May and June, white.

Culture &c. as above.

C. Oxyacantha (*Common Hawthorn*; *May*).—A well-known British tree 10–20 ft. high. Leaves obovate wedge-shaped, 3-cleft or pinnately cut, smooth, shining. Flowers in May and June, white, sometimes pink, sweet-scented. Fruit crimson-red, occasionally orange.

There are many fine forms of the Hawthorn, the best being *aurantiaca*, with orange-yellow fruits; *avrea*, distinct, with golden-yellow fruits; *ericarpa*, with woolly fruits and clear whitish bark; *ficifolia*, *laciniata*, and *pteridifolia*, all with finely cut leaves; *flore-pleno alba*, double white flowers changing to pink with age; *præcox*, the Glastonbury Thorn,

sometimes in flower at Christmas in mild winters; *carminata* or *rosea*, pink petals with white claws; *rosea-superba* (or *punica*), with large, dark red flowers; Paul's Double Scarlet, and several others.

Culture &c. as above. The Scarlet Thorns, or 'Mays' as they are popularly termed, are extensively planted in villa and suburban gardens, and are usually grown as mop-headed standards grafted on the commoner kind.

C. pinnatifida.—A distinct Chinese Thorn 6–10 ft. high, with broadly oval leaves divided into 2–4 long pointed toothed lobes on each side; they are smooth above and downy on the nerves beneath. The white flowers appear in May in erect corymbose clusters before many of the other Thorns. The variety *major* is more ornamental than the type. It has long-stalked, lobed and pinnately divided leaves, large white flowers in clusters, and bright red pear-shaped fruits about $\frac{3}{4}$ in. in diameter. It looks very handsome in autumn.

Culture &c. as above, p. 408.

C. Pyracantha (*Evergreen Thorn*; *Pyracanth*).—A beautiful and well-known tree 10–20 ft. high, native of S. Europe. Leaves smooth, ovate lance-shaped, crenate. Flowers in May, white. Fruits of a beautiful scarlet, as large as peas, remaining on the trees during winter. There are only one or two varieties, of which *Lalandi*, which fruits more freely than the type, and *pauciflora*, a dwarfier form, are the best.

The Pyracanth does well on a wall, and looks handsome grown as a pyramidal tree. As the birds are very fond of the fruits, a net over them will check their thieving.

Culture &c. as above, p. 408.

C. sinaica (*C. Aronia*; *C. maroccana*). A native of S. Europe 15–20 ft. high. Leaves wedge-shaped, 3-lobed and pinnately cut, smooth; stipules cut. Flowers in May and June, white. Fruit scarlet.

Culture &c. as above, p. 408.

C. tanacetifolia (*Tansy-leaved Thorn*). A native of the Levant, 12–20 ft. high. Leaves deeply cut, downy, with oblong-acute, few-toothed lobes. Flowers in May, white; calyx lobes acute, hairy, reflexed. Fruit greenish-yellow, round.

Culture &c. as above, p. 408.

COTONEASTER.—A genus containing about 20 species of erect or trailing trees or shrubs. Leaves simple, leathery, entire, usually woolly or white beneath (a fact not mentioned again in the descriptions below), often evergreen. Flowers in axillary and terminal cymes, or solitary. Calyx-tube 5-lobed. Petals 5. Stamens many. Fruit an ovoid, top-shaped, or roundish drupe, containing 2-5 seeded stones.

According to soil, situation, and mildness or otherwise of the season, the deciduous kinds either retain their leaves for a greater portion of the year, or lose them at the usual period. The evergreen kinds, even when not in bloom or berry, have a peculiarly graceful and ornamental appearance in the depth of winter. The dwarfier kinds might be used with advantage for covering banks or rising ground, or for making thickets or coverts.

The accompanying list will show at a glance the evergreen and the deciduous species.

Evergreen

C. buxifolia
C. microphylla
C. pannosa
C. rotundifolia
C. thymifolia

Deciduous

C. acuminata
C. affinis
C. bacillaris
C. frigida
C. horizontalis
C. integerrima
C. laxiflora
C. multiflora
C. Nummularia
C. Simonsi
C. tomentosa.

Culture and Propagation.—Cotoneasters grow well in ordinary soil, and are ornamental trained against a wall, or to fill up a corner in the shrubbery or border. They may be increased by seeds sown in spring, or better still in autumn as soon as ripe; by cuttings and layers in autumn, or by grafting in March on *C. Simonsi* and *C. integerrima*, the Quince (*Pyrus vulgaris*), or the Hawthorn (*Crataegus Oxyacantha*). Plants are so readily raised by means of seeds, cuttings, and layers that it is astonishing that grafting is at all practised.

C. acuminata.—A deciduous Himalayan species 10 ft. or more high. Leaves 1½-2 in. long, tapering to a point, very hairy when young, smooth when old. Flowers pinky white, 2 or more together on very short cymes. Fruit large, hand-some, scarlet.

Culture &c. as above.

C. affinis.—Closely related to *C. bacillaris* and *C. frigida*, native of Nepal. It is shorter and stiffer in habit than the two species mentioned, and has the under surface of the leaves covered with a woolly down.

Culture &c. as above.

C. bacillaris.—A bold, large-growing deciduous species, 15-20 ft. high, from Nepal, with oblong or obovate lance-shaped leaves 1-3 in. long, narrowed into a stalk. Flowers white, ½ in. across, in clusters along the slender shoots. Fruits in graceful, drooping clusters, dark brown or black.

There is a variety called *floribunda* which differs but little if at all from the type, and another called *obtusa*, in which the leaves are blunt instead of pointed.

Culture &c. as above.

C. buxifolia.—An evergreen species, native of the Nilghiri Mts., 3-10 ft. high, with drooping branches. Leaves elliptic-acute or ovate, like those of the common Box (*Buxus sempervirens*) in shape. Flowers in April and May, white, 2-6 in a short cyme.

Culture &c. as above. This is a very free-growing species, and attains large proportions.

C. frigida.—An almost evergreen species about 10 ft. high, native of Nepal. Leaves more or less oblong lance-shaped, acute, 3-5 in. long. Flowers in April and May, white, in woolly cymes, followed by large clusters of bright red fruits about the size of small Peas.

Culture &c. as above. This is one of the most ornamental species, especially when studded with its brilliant fruits.

C. horizontalis.—As a bush in the open this fine species grows only about 2 ft. high, but against a wall it will reach a height of 6 ft. or more. The young branches are covered with a thick brown wool, but the leaves—about ½ in. long—are smooth, shining green, and are set very close together, bright red or yellow in autumn. Flowers in May and June, small pinkywhite in great profusion, succeeded by round red attractive fruits in autumn and winter.

Culture &c. as above.

C. integerrima (*C. vulgaris*; *Mespilus Cotoneaster*).—A shrub 3-5 ft. high, native of Carnarvonshire, Europe and W. Asia. Leaves broadly elliptic-oblong, blunt or

acute. Flowers in May and June, white or reddish. Fruit round, red, drooping. In the variety *melanocarpa* the fruits are black.

Culture &c. as above.

C. laxiflora.—A Siberian species with oblong blunt leaves, smooth above, woolly beneath. Flowers pinky white in long drooping clusters. This species is closely related to *C. integerrima*.

Culture &c. as above.

C. microphylla.—A pretty trailing evergreen 3-4 ft. high, native of Nepal. Leaves about $\frac{1}{2}$ in. long, ovate or obovate, acute or blunt, deep glossy green. Flowers in April and May, $\frac{1}{2}$ in. across, white, in great profusion, followed by small deep red berries, which look particularly cheerful in winter. The variety *glacialis* (or *congesta*) is a dwarf alpine form, with smaller pinky flowers, and paler green leaves, glaucous and smoothish beneath.

Culture &c. as above. This species may be grown as a bush in most parts of the kingdom, but in bleak northern parts it is best with the shelter of a wall.

C. multiflora (*C. reflexa*).—A graceful shrub 6 ft. or more high, with slender, drooping branches, native of Persia, N.E. India &c. Leaves deciduous, 1-2 in. long, smooth above, woolly or silky beneath when young. Flowers white, 3-10 in a cyme. Fruits pear-shaped, beautiful carmine-red.

Culture &c. as above.

C. Nummularia.—A distinct and pretty almost evergreen shrub, 10-15 ft. high, native of Kashmir, Western Tibet &c. Leaves roundish, apiculate. Flowers in April and May, white, in woolly cymes. Fruit small, round, black.

Culture &c. as above.

C. pannosa.—A free and elegant Chinese evergreen, with ovate leaves about $\frac{3}{4}$ in. long, covered with a thick wool, white at first, changing to brown. Flowers white, with a very woolly calyx. Fruits pear-shaped, dull red, about $\frac{1}{4}$ in. long.

Culture &c. as above.

C. rotundifolia.—A beautiful Himalayan shrub 4-5 ft. high, with roundish, dark green, glossy leaves, about $\frac{1}{2}$ in. long, abruptly pointed, hairy. Flowers solitary, white. Fruits bright scarlet, lasting well

into spring. The variety *prostrata* has a more drooping or trailing habit.

Culture &c. as above.

C. sikkimensis.—A deciduous shrub, native of the Sikkim Himalayas. It has large elliptic leaves 4-5 in. long, dull green above, and grey-green beneath. The white flowers are produced in compound umbels in spring, and are succeeded by bright coral-red fruits in autumn.

Culture &c. as above. This and *C. frigida* are remarkable for having the largest leaves in the genus.

C. Simonsi.—Perhaps one of the best species grown. It is a native of the Khasia hills, and grows 8-12 ft. high. Leaves about 1 in. long, rhomboid-roundish, glossy green above, silky beneath. Flowers in April, solitary or twin, almost stalkless. Fruit bright scarlet-red.

Culture &c. as above. This species is largely used as a stock upon which others are grafted.

C. thymifolia.—A pretty evergreen, less than 1 ft. high, native of the temperate Himalayas, with crowded branches, small oblong-ovate, dark, shining green leaves, pinkish flowers in April, and scarlet fruits in autumn and winter.

Culture &c. as above. This species is closely related to and sometimes confused with *C. microphylla*.

C. tomentosa.—A native of Central and S. Europe, with bluntly elliptic leaves $\frac{1}{2}$ -2 in. long, woolly. Flowers white, 4-5 in a cluster with a very woolly calyx. Fruits red.

Culture &c. as above.

PHOTINIA.—A genus containing 20 species of smooth or downy, evergreen trees or shrubs. Leaves alternate, leathery, simple, entire or serrate. Flowers in terminal corymbs or panicles. Calyx-lobes 5, ovate blunt. Petals 5. Stamens up to 20. Fruit a drupe or ovoid berry.

Culture and Propagation.—Photinias like a somewhat light loamy soil, and are worth growing chiefly on account of their bold and beautiful foliage. Trained against sunny walls the plants do well, but in bleak parts of the country they may require a little protection in winter. They may be increased by cuttings of the side shoots 2-3 in. long, in sandy soil, under a glass during the summer months. They may also be grafted close to the

ground in March and April, on the Quince stock. See article on Grafting, p. 52.

P. arbutifolia (*Cratægus arbutifolia*). *Californian Maybush*.—A Californian tree 10–20 ft. high, with young branches and leaf stalks bright red. Leaves oblong lance-shaped acute, serrated. Flowers in summer, white, in long panicles.

Culture &c. as above.

P. elliptica.—A native of Nepal, 30 ft. high. Leaves elliptic, toothed, downy beneath. Flowers white, in clusters covered with a rusty down. Fruit yellow, downy.

Culture &c. as above.

P. japonica (*Eriobotrya japonica*).—*Japan Medlar* or *Quince*; *Loquat*.—A handsome Japanese tree 10–20 ft. high. Leaves large, oblong, wrinkled, downy beneath. Flowers late in autumn, white, in drooping racemes. Fruit about the size of a Pippin Apple, pale orange-red, downy, in large clusters; scarcely ever produced out of doors in the British Islands.

Culture &c. as above.

P. serrulata (*Cratægus glabra*).—*Chinese Hawthorn*.—A handsome Chinese and Japanese tree 10–20 ft. high. Leaves Laurel-like, leathery, oblong acute, serrulate. Flowers from April to July, white, small, in flat corymbs.

Culture &c. as above.

POURTHIÆA.—A genus of evergreen or deciduous shrubs closely resembling the Photinias and almost identical with them in structure. The leaves are usually more or less lance-shaped and serrate with bristly stipules, and the flowers are borne in cymes or corymbs. Calyx sharply 5-toothed. Petals 5, twisted in bud, with an emarginate or lacerated apex. Stamens 20. Fruits about the size of a Pea, fleshy.

P. arguta (*Photinia arguta*).—A handsome shrub native of the Khasia Hills, with downy young shoots, and lance-shaped or elliptic oblong sharply serrate leaves 3–6 in. long. Flowers in summer, white.

Culture and Propagation.—This seems to be the only species at present cultivated, and even it is not well-known. There are about a dozen species altogether known, and they resemble each

other a good deal in appearance. The leaves, however, are much narrower and shorter in some than in others. The plants flourish in light sandy loam, and are more valuable for their foliage than anything else. They may be trained against walls like the Photinias, and may also be increased by cuttings of the more or less ripened shoots in summer and autumn inserted under handlights.

RHAPHIOLEPIS (JAPANESE HAWTHORN).—A genus with a few species of rather smooth evergreen trees and shrubs, with alternate simple leathery leaves, entire or serrulate. Flowers in panicles or corymbs. Calyx lobes 5, deciduous. Petals 5, clawed, oblong, acute. Stamens many, deciduous. Berry pulpy.

Culture and Propagation.—These like a rich loam, peat, and sandy soil in warm situations, protected from the north and east. Cuttings of the half-ripened shoots will root in sandy soil under a glass during the summer months.

R. ovata (*R. japonica integerrima*). A beautiful Japanese shrub 2–4 ft. high. Leaves 2–3 in. long, broadly obovate, dark green and shining above. Flowers in June, less than 1 in. across, snowy white, fragrant.

R. indica, the *East Indian Hawthorn*, and its variety *salicifolia*, are also beautiful plants, but not quite hardy enough for our climate, except perhaps on sunny walls in mild places in the south and west.

Culture &c. as above.

STRANVÆSIA.—A genus with only one species, here described with the generic characters:—

S. glaucescens.—An ornamental evergreen tree, about 20 ft. high when fully grown, native of the Khasia Hills and other parts of the temperate Himalayas. It has alternate stalked, simple leathery leaves, ovate lance-shaped in outline with serrulate edges, and bristly stipules at the base. The white flowers appear in June in axillary and terminal clusters, and in a wild state are succeeded by small orange-coloured fruits. The bell-shaped calyx has 5 short erect blunt lobes. Petals 5, spreading, hairy at the base. Stamens about 20. Ovary hairy, half-superior, 5-celled. Styles 5, united at the base.

Culture and Propagation.—This tree is scarcely hardy enough for growing in

the open air in the northern parts of the kingdom. It may be planted against a south wall in milder parts, or even grown as a bush in the most favourable localities of the south of England and Ireland. A good well-drained garden soil or sandy loam will suit it well. It may be increased by cuttings of the half-ripened shoots inserted in sandy soil under a handlight in summer; or it may be grafted in March and April upon stocks of the common Hawthorn or upon *Crataegus coccinea*.

AMELANCHIER (JUNE BERRY).—

This genus contains 4 species of pretty shrubs or bushes, with alternate, stalked, simple, deciduous, entire or serrate, often woolly leaves. Flowers in racemes. Calyx lobes 5, recurved, persistent. Petals 5. Stamens many. Berry small.

Culture and Propagation.—Amelanchiers thrive in a rich loamy soil, and may be propagated in the same way as the Cotoneasters (p. 410) by sowing seeds out of doors or in cold frames as soon as ripe; by cuttings of the half-ripened shoots inserted in sandy soil under a handlight in summer; by layering the shoots in autumn; or by grafting on the common *A. vulgaris* about March.

A. alnifolia.—A pretty N.W. American shrub, about 8 ft. high. Leaves variable, sometimes entire, sometimes serrate. Flowers in spring, white, in compact racemes, succeeded by brilliant purple berries.

Culture &c. as above.

A. canadensis (*Pyrus Botryapium*).—*Grape Pear.*—A very handsome Canadian shrub 6-8 ft. or more high. Leaves oblong elliptic, tailed, hairy when young, and assuming rich mellow tints in autumn, the under surface being of a deep reddish or brownish purple colour. Flowers in April, snowy white, in great profusion. Fruits purple-crimson. There are several varieties, of which *florida*, *ovalis*, *parvifolia*, *rotundifolia*, *oblongifolia* are more or less easily recognised by their foliage.

Culture &c. Bullfinches are very fond of the flower buds.

A. oligocarpa.—A bushy shrub 2-4 ft. high, native of the Eastern United States. It has smooth oblong acute leaves with crenulate edges, and produces its white flowers, each about $\frac{3}{4}$ in. across, in April

and May, either solitary or in pairs, but rarely three or four in a raceme.

Culture &c. as above.

A. sanguinea.—This differs from *A. canadensis* chiefly in having shorter racemes of flowers, oblong serrate leaves, and blackish-purple fruits. In the 'Kew Handlist' it is given as a synonym of *A. canadensis*.

Culture &c. as above.

A. vulgaris (*Mespilus Amelanchier*). This pretty European shrub, 3-9 ft. high or more, has been cultivated for about 300 years. Leaves roundish-oval, downy beneath, when young. Flowers in April, white. Fruits dark purple.

Culture &c. as above.

OSTEOMELES.—A small genus of trees and shrubs having alternate stalked leathery leaves, usually simple and evergreen, but compound in the species described below. Flowers few or numerous, borne in corymbose clusters. Calyx more or less bell-shaped, adnate to the carpels, and having 5 lance- or awl-shaped persistent lobes. Petals 5, oblong spreading. Stamens 10 or more. Carpels 5. Drupe fleshy.

O. anthyllidifolia.—A remarkable and interesting Chinese evergreen shrub about 5 ft. high, with slightly twisted and gracefully inflected branches of a violet-brown colour, and downy in a young state. The oddly pinnate leaves consist of 10 or 11 pairs of small opposite or alternate oval-pointed leaflets, which are very downy on both sides. From 10-25 long-stalked pure white Hawthorn-like flowers are borne in a loose corymbose cluster at the ends of the young shoots, and are succeeded by small Cotoneaster-like fruits, which change from green to violet-red, and then black, with a hoary bloom when fully ripe.

Culture and Propagation.—This is a comparatively new introduction to cultivation, and is too tender for growing in the open air, except in the very mildest parts of the country and in sheltered spots. It flourishes in a mixture of sandy loam and peat, and may be increased by seeds—if obtainable—which should be sown as soon as ripe in cold frames or greenhouses. They will probably take a long time to germinate, perhaps 12 months. Cuttings of the half-ripened shoots will root in a mixture of sandy loam and peat in July and August if placed under a handlight and

kept shaded and close for a time. The rooted cuttings may be potted up in spring. Grafting has also been practised, and

excellent results have been obtained in Paris by using *Cotoneaster acuminata* as a stock.

XI. SAXIFRAGEÆ—Rockfoil Order

An order containing over 500 species of herbs, shrubs, or trees, very variable in habit. Flowers hermaphrodite, rarely 1-sexed, or polygamous-dicecious. Calyx 5-(rarely 4-12)-parted, free or adnate to the ovary. Petals usually 4 or 5, rarely none, generally perigynous, often small. Stamens usually 4 or 5, or 8 or 10, rarely more, perigynous or epigynous, sometimes hypogynous, filaments free, anthers very often didymous (united in pairs). Ovary inferior or superior, usually consisting of 2 carpels cohering more or less by their face, but distinct and diverging at the apex. Fruit usually a capsule or berry.

This order and the preceding one (Rosaceæ) are very closely related to each other, and it is sometimes difficult to decide whether a plant belongs to one or the other. When in doubt a reference to the 2 united and divergent carpels and to the fewer stamens in Saxifrageæ will usually settle the point.

Tribe I. SAXIFRAGEÆ.—Herbs, often scapigerous. Leaves usually alternate, without stipules. Flowers nearly always pentamerous (with the parts in fives). Ovary 1-3-celled.

ASTILBE.—A genus with 6 species of tall, smooth or hairy perennials, with the habit of *Spiræa Aruncus* (see p. 364). Leaves twice or thrice ternate, and more or less divided, with deeply serrated lobes, and stalks dilated at the base. Flowers often polygamous-dicecious, in terminal racemes or spikes. Calyx lobes 5, rarely 4. Petals 4, 5, or none, inserted at the base of the calyx. Stamens 8 or 10, inserted with the linear petals. Carpels 2-3 scarcely united at the base.

Culture and Propagation.—The Astilbes are graceful feathery plants suitable for the mixed border. They thrive in any good garden soil and like plenty of water during active growth. They are easily increased by dividing the rootstocks early in spring.

A. chinensis.—A graceful Chinese species resembling *A. japonica* in appearance. It has however much taller and stronger flower stems, more loosely branched, and the rose-coloured flowers are larger and very effective right through the summer months up to September.

Culture &c. as above.

A. japonica (*Spiræa japonica*; *S. barbata*; *Hoteia japonica*).—A well-known graceful Japanese plant 1-2 ft. high, with thrice ternate or pinnate leaves, and coarsely serrated leaflets. Flowers in

early summer, small, pure white, in erect, pyramidal trusses. There is a variegated form but seldom seen.

Culture and Propagation.—This species is usually grown in pots and sold in thousands every spring as *Spiræa japonica*, a name properly belonging to a Rosaceous shrub described at p. 367. The plants are perfectly hardy in the border, but the soil should be rich and well-manured to develop them. Imported clumps may always be obtained about September. Grown in shaded or partially shaded parts of the border or rockery the plants retain their graceful beauty for a long time. After flowering the clumps may be divided and well watered into their new positions.

A. Lemoinei.—This is the name given to a French hybrid between *A. Thunbergi* and *Spiræa astilboides floribunda* (p. 364). If the parentage be correct it proves that plants belonging to two natural orders—Rosaceæ and Saxifrageæ—may be crossed with each other—a very remarkable thing and probably unique.

Culture &c. as above.

A. rivularis.—A vigorous handsome Nepalese perennial 3-4 ft. high. Leaves twice ternate, with ovate doubly serrate leaflets hairy beneath. Flowers late in summer, yellowish-white, in upright clusters.

Culture &c. as above. This is a grand plant for the sides of ponds, streams &c. or in damp parts of the flower border. It is easily increased by dividing the roots in spring when growth is commencing.

A. rubra.—A somewhat rare and pretty Indian species 4-6 ft. high, with twice ternate leaves; leaflets obliquely cordate pointed, 1-2 in. long, serrated. Flowers in summer and autumn, rosy, in dense panicles.

Culture &c. as above.

A. Thunbergi.—A pretty little Japanese undershrub about 1½ ft. high. Leaves oddly pinnate or twice pinnate, with broad, yellowish-green, sharply toothed leaflets. Flowers in May, small, white, in erect, dense, pyramidal clusters, with reddish and rather downy stalks.

Culture &c. as above.

RODGERSIA (RODGERS'S BRONZE LEAF).—A genus with only one cultivated species, described below with the generic characters:—

R. podophylla (R. japonica).—A charming herbaceous Japanese perennial with a thick, scaly rootstock and large alternate leaves; lower ones long-stalked, palmately or peltately 5-cleft, 1 to 3 ft. across; upper ones 3-lobed, with sessile, sharply serrated segments, cut at the apex; leaf-stalks dilated at the base, with papery adnate stipules. Flowers in June and July, yellowish-white, in scorpioid cymes disposed in large panicles.

Culture and Propagation.—This plant thrives in a peaty soil and a rather shaded situation. A mulching or top-dressing of well-rotted manure over the crowns after the leaves have withered away will be of great benefit every year. It may be increased by cutting up the rootstock in early spring, but the plants should not be disturbed unless they have become too large.

Other species of *Rodgersia* have been discovered of late years, and may soon be introduced to cultivation from their habitats in China. *R. asculifolia*, with yellowish-white flowers; *R. Henrici*, with deep purple flowers; and *R. pinnata*, with pale rose or white flowers, are the species referred to.

SAXIFRAGA (ROCKFOIL; BREAKSTONE).—A genus with about 160 species of beautiful, mostly perennial rock plants,

very smooth, hairy or glandular, erect or decumbent. Leaves various; the lower ones often in rosettes; the upper ones usually alternate, sheathing at the base. Flowers usually in panicles or corymbs, white or yellow, rarely purple or pink. Calyx lobes 5. Petals 5, usually equal, sometimes fringed or glandular at the base, perigynous or nearly hypogynous. Stamens 10, rarely 5. Ovary superior or half inferior, 2-lobed at the apex, very rarely with 2 free carpels. Capsule 2-beaked.

Culture and Propagation.—The Rockfoils are beautiful garden plants, chiefly natives of the north temperate or arctic regions, and are very easily grown in ordinary soil with stone and rocks abounding. The plants are easily increased by division in spring, or from seeds sown in cold frames as soon as ripe, while many kinds with creeping or trailing stems are also readily increased by cuttings of the shoots inserted in sandy moist soil in spring in cold frames. With a few exceptions, which have been noted in the proper places, most of the species like rather higher ground than the ordinary level, and are thus eminently suitable for the rock garden in raised positions, where they will not run the risk of having stagnant moisture at the roots. During the active period of growth however they like an abundance of water, and as they gradually begin to pass from this stage, and to ripen their seeds, drier conditions are necessary. Besides the kinds described below there are many forms which are probably hybrids, and they resemble one another so closely that it is practically impossible to distinguish them by mere written descriptions, although they appear distinct enough to the eye.

As there are so many sections of *Saxifraga* recognised by botanists it may be as well to give them in a tabulated form, showing the species belonging to each section.

1. *Cymbalaria.*—Usually annual or biennial herbs with fleshy, stalked, 5-9-lobed leaves. Petals more or less obovate oblong, yellow or orange.

S. Cymbalaria *S. huetiana*

2. *Tridactylites.*—Herbs with rosettes of fleshy, wedge-shaped 3-5-7-lobed or entire leaves, narrowed into a petiole. Petals white, obovate, wedge-shaped, emarginate.

S. adscendens
S. petræa

S. tridactylites

Flowers solitary or corymbose, white or straw-yellow. Calyx tube rather long.

3. *Nephrophyllum*.—Stems slender, annual or biennial, rarely perennial, usually solitary, erect, leafy. Radical leaves stalked, kidney-shaped, lobed. Flowers few, often large, white. Petals obovate, wedge-shaped, or narrowed into a claw. Calyx tube short, sepals united at the base.

S. atlantica
S. biternata
S. Boissieri
S. granulata

S. irrigua
S. lactea
S. latepetiolata

S. ajugifolia
S. androsacea
S. aphylla
S. aquatica
S. Camposi
S. conifera
S. cuneata
S. exarata

S. geranioides
S. globulifera
S. hypnoides
S. mixta
S. muscoides
S. pentadactylis
S. trifurcata

4. *Peltiphyllum*.—This section contains only one species—*S. peltata*—described below.

5. *Miscopetalum*.—Stems leafy, stolons none. Leaves alternate, roundish and thickish, more or less slightly lobed or crenate. Flowers in panicles, white, spotted, with oblong petals. Calyx segments almost free. Ovary free. The only species belonging to this section is *S. rotundifolia*.

6. *Hirculus*.—Stems leafy. Leaves various, entire, with curved nerves, and narrowed into a hairy petiole. Flowers yellow, with oblong or rarely obovate petals. Sepals free, erect, or spreading, or reflexed.

There are several species belonging to this section, but only two, *S. diversifolia* and *S. Hirculus*, are described below.

7. *Boraphila*.—Stem almost absent. Radical leaves stalked. Scape paniculate. Calyx tube conical, adhering to the base of ovary. Petals white, yellowish-green, or purplish, broadly or narrowly elliptic or lance-shaped, rarely obovate.

S. Clusi
S. hieracifolia
S. integrifolia
S. leucanthemifolia
S. mertensiana

S. nivalis
S. pallida
S. pennsylvanica
S. virginiensis

8. *Hydatica*.—Stems erect, scape-like. Leaves leathery, rarely flaccid, roundish or wedge-shaped, in rosettes on the sterile stems. Calyx lobes and ovary nearly free. Petals white, sometimes unequal, 3 being smaller than the other two.

S. cortusaeformis
S. cuscuteformis

S. Fortunei
S. sarmentosa

9. *Dactyloides*.—Stems usually decumbent, spreading or compact. Leaves persistent, often 3-5-cleft, or pedately or palmately cut. Flower stems often leafy.

10. *Trachyphyllum*.—Leaves fleshy or leathery, stiff, entire, beset with spiny or bristly hairs. Flowers in cymose racemes or panicles. Petals oblong or more or less roundish obovate, sometimes absent.

S. aizoides
S. aspera
S. bronchialis

S. flagellaris
S. tenella

11. *Robertsonia*.—Stems perennial, woody, with a rosette of leaves at the apex. Leaves roundish or obovate, crenate or serrate, with slightly cartilaginous margins, heart-shaped or wedge-shaped at the base, and ending in a flat or half-round stalk. Flowers in panicles, white, spotted with yellow or purple; petals more or less obovate oblong.

S. cuneifolia
S. Geum

S. umbrosa

12. *Aizoonia*.—More or less erect, often tufted herbs. Leaves in rosettes, perennial, very leathery, with cartilaginous margins, pitted, often porous at the apex. Flowers in panicles or corymbs, white, sometimes spotted with purple; or yellow, rarely red. Petals obovate or wedge-shaped, rarely lance-shaped.

S. Aizoon
S. Cotyledon
S. crustata
S. florulenta

S. Hosti
S. lingulata
S. longifolia
S. mutata

13. *Kabschia*.—Stems perennial, clothed with densely imbricating leaves. Lower leaves thickish or fleshy, tongue-shaped or obovate spoon-shaped, pitted at the margin. Flowers in cymose racemes or panicles, white or sometimes yellow, rarely purple. Petals more or less roundish or wedge-shaped.

S. apiculata
S. aretioides
S. burseriana
S. cæsia
S. diapiensioides
S. imbricata
S. juniperifolia

S. Kotschyi
S. luteo-viridis
S. marginata
S. media
S. pseudo-sancta
S. rocheliana
S. sancta

S. scardica *S. valdensis*
S. Tombeanensis

14. *Porphyreon*; *Muscoideæ*.—Leaves imbricated, small, opposite, very often porous at the apex. Flowers solitary, red, or purple. Petals oblong wedge-shaped, or lanceolate.

S. biflora *S. oppositifolia*
S. macropetala *S. retusa*

15. *Bergenia*.—Rootstock thick, leaves large, with stalks dilated at the base. Petals white, red, or purple. Includes *MEGASEA* which is kept up as a distinct genus by some authorities.

S. cordifolia *S. purpurascens*
S. crassifolia *S. Stracheyi*
S. ligulata

S. adscendens.—A European and N. American annual 3 in. high. Leaves fleshy, 3-lobed; lower ones cordate with cut lobes. Flowers in April, white, with hairy stalks and calyx. *S. petræa* and *S. tridactylites* are very closely related.

Culture and Propagation.—This species is little more than a botanical curiosity. It will flourish in cool damp parts of the rockery facing north or east, and may be increased by seeds sown as soon as ripe or in spring in the open air.

S. aizoides.—A British and European alpine with decumbent, tufted, much-branched stems, 3-8 in. long. Leaves linear oblong, crowded below, scattered upwards, $\frac{1}{2}$ -2 in. long; lower ones reflexed, often ciliated. Flowers in summer, $\frac{1}{2}$ in. across, orange or golden yellow, with red dots.

Culture &c. as for *S. flagellaris*, p. 420.

S. Aizoon (*S. intacta*).—Native of Europe and N. America, 5-10 in. high. Lower leaves clustered, silvery, persistent, thick, spoon-shaped, with white, cartilaginous, toothed edges. Flowers in June, creamy-white, often spotted at the base; petals obovate; scape downy, clammy. There are very many varieties of this species, among the best being *carinthiaca* (or *gracilis*), *robusta*, *recta*.

Culture and Propagation.—A good rock plant; it likes plenty of sun, and may be planted so as to face outwards more or less vertically from the face of the rocks, which may be either limestone or granite. The soil however should be deep and rich, so that the roots may penetrate after the moisture between the fissures. Increased by seeds and division.

S. ajugæfolia.—A pretty little tufted species from the Pyrenees. It has small and rather thick fleshy bright green leaves, and 1-3 white flowers with yellow anthers on a stalk, produced in July.

Culture &c. as above. This species luxuriates in a moist but well-drained situation, and is an excellent plant for carpeting the rockery in positions facing north or east, or for making edgings to beds or shrubberies in the shade.

S. Andrewsii.—A hybrid between *S. Geum* and *S. Aizoon*, about 6-12 in. high. Leaves long, spoon-shaped, obtuse, smooth, rather thick, narrowed at the base into a slightly fringed stalk, and having a membranous margin. Flowers in early summer, white, dotted with purple. *S. guthrieana* is very similar to this.

Culture &c. as above for *S. Aizoon*.

S. androsacea.—A mossy species found on damp rocks on the higher Alps. The small deep green shining leaves are spoon-shaped or obovate wedge-shaped, with an entire or 3-5-toothed apex. Flowers 1-3 on a stem, pure white, produced in June and July.

Culture &c. as above for *S. ajugæfolia*.

S. aphylla.—A mossy Alpine species with rosettes of entire or 3-5-toothed fleshy, bright green leaves. The bright golden-yellow flowers appear in June and July, and are usually borne singly on the top of the stalk, but there are occasionally two blossoms on one stem.

Culture &c. as above for *S. ajugæfolia*.

S. apiculata.—A charming mossy Saxifrage supposed to be a hybrid between *S. aretioides* and *S. scardica*. It has dense rosettes or tufts of small thick linear acute leaves, and produces 6-9 flowers of a soft pale primrose-yellow colour on very hairy yellow-green stalks 3-5 in. high from February to April.

Culture &c. as for *S. burseriana*. It makes a charming pot plant, and also fine carpets in the rock garden. It is better than *S. sancta* for this purpose, but does not flower so freely.

S. aquatica.—A beautiful Pyrenean species with fleshy and slightly hairy deeply 3-lobed leaves dilated at the base. The large white or rarely yellow flowers

appear in July and August on stalks 12-18 in. high, and their beauty is enhanced by the purple-coloured anthers in the centre.

Culture &c. as above for *S. ajuga-folia*. This species grows naturally in moist and cool places, and may be given similar situations in the rockery. It must, however, be fully exposed to the air.

S. aretioides.—A tiny Pyrenean species about 2 in. high. Leaves crowded, linear strap-shaped, upright, tipped with a sharp point, margins fringed. Flowers from May to July, golden-yellow, on stalks covered with clammy down. There are several varieties, among which may be noted *alba*, with whitish flowers; *præcox*, which flowers earlier than the type; and *primulina*, with soft primrose-yellow blossoms.

Culture &c. as above for *S. burseriana*.

S. aspera.—A more or less tufted species from the Alps and Pyrenees closely related to *S. tenella*. It has rosettes of small lance-shaped linear leaves ending in a sharp point, with ciliated margins, and of a whitish shining green. The yellowish-white flowers with a deeper yellow base and golden-yellow anthers appear in June and July. There are several forms of this species.

Culture &c. as for *S. flagellaris*, p. 420.

S. atlantica.—A compact dwarf-growing Rockfoil, native of the moist rocks of Southern Spain and Algeria. The light green roundish leaves have lobed or crenate edges, and the large white sweet-scented flowers, 3-7 on a slender stem, appear in April and May.

Culture &c. as for *S. granulata*, p. 421.

S. biflora.—A pretty and very variable species of the *oppositifolia* group, native of the high mountains of Central Europe. The lower leaves of the trailing branched stems are obovate roundish, while the upper ones are more spoon-shaped, and all are small, thick and fleshy, bright green or purplish. Notwithstanding the specific name, more than two flowers are often borne on the stems. They appear in June and July, and vary in colour from deep violet to dark blue, and are occasionally reddish or white.

Culture &c. as for *S. oppositifolia*, p. 424.

S. biternata.—A hairy tufted species, native of the Spanish mountains, with

long-stalked, twice ternate, bright green leaves, the lobes of which are more or less deeply divided and bluntly toothed. The white flowers, with spoon-shaped shallow notched petals, appear about July.

Culture &c. as for *S. granulata* below.

S. Boydi.—A charming Saxifrage said to be a hybrid between the yellow-flowered *S. aretioides* and the milky-white *S. burseriana*. The rosettes or tufts of leaves more nearly resemble those of the latter parent, but are linear and end abruptly in a point. The flowers are about $\frac{3}{4}$ in. across, and appear from March to June. They are soft primrose-yellow in colour, and 1-3, rarely more, are borne on the stems. The white-flowered variety *alba* is very similar in appearance, but shows more of the *burseriana* blood.

Culture &c. as for *S. burseriana*.

S. bronchialis.—A native of Northern Asia and N. America about 6 in. high, with ascending stems, densely leafy at the base. Leaves stiffish, linear lance-shaped, with ciliate or somewhat spiny margins and a pointed apex. The yellowish or creamy white flowers with oblong petals appear in May, and are ornamented with numerous orange-red dots. From 3 to 10 blossoms are borne on a more or less hairy stem.

Culture &c. as for *S. flagellaris*, p. 420.

S. burseriana.—A densely tufted, moss-like plant, about 2 in. high, native of the Alps. Leaves in rosettes, triquetrous, smooth, glaucous. Flowers from March to June, usually one on a slender red stem, milky-white, large, and veined with yellow. The variety *major* is a beautiful rock plant with acute fringed leaves in dense rosettes, and large white flowers on stalks about 2 in. high.

Culture &c. as given above under general instructions. This species likes a high and well-drained position in the rockery, and is almost sure to fail if grown in moist, marshy, or ill-drained spots. Once established in suitable positions it makes very fine carpets of green, studded with white flowers.

S. cæsia.—A pretty native of the Alps and Pyrenees forming dense silvery tufts often less than 1 in. high. Leaves linear-oblong, recurved, keeled, margined with white, crustaceous dots. Flowers in

early summer, white, about $\frac{1}{3}$ in. across, on thread-like stalks about 3 in. high.

Culture &c. as above for *S. burseriana*.

S. cæspitosa.—A densely tufted British species about 3 in. high. Lower leaves wedge-shaped, 3-5-lobed; upper ones undivided. Flowers from June to August, white, bell-shaped, on stalks usually covered with short glandular down.

Culture &c. as for *S. ajugæfolia* above.

S. Camposi (*S. Wallacei*).—A native of Spain, 3-6 in. high, leaves very variable, $\frac{1}{4}$ - $\frac{1}{2}$ in. across, 3-5-cleft, with obtuse or acute teeth, or broader and deeply 3-5-lobed. Flowers in early summer, white, about $\frac{3}{8}$ in. across.

Culture &c. as above for *S. ajugæfolia*, p. 417.

S. Clusi.—A native of the Pyrenees, where it grows in marshy soil, and on the banks of brooks. It has very short stems with rosettes of thin spoon-shaped and linear leaves more or less toothed and hairy. The white flowers, spotted with yellow, appear in June and July.

Culture &c. as above indicated in the general instructions under Saxifraga. This species likes a moist cool part of the rockery.

S. conifera.—A peculiar Saxifrage from the mountainous parts of Spain. It forms dense clusters of small lance-shaped linear leathery leaves, ending in a sharp point, and more or less densely covered with a soft down. The flowers appear in June and July, from 3 to 9 in a panicle.

Culture &c. as above for *S. ajugæfolia*, p. 417.

S. cordifolia (*Megasea cordifolia*).—A pretty Siberian species about 1 ft. high. Leaves large, fleshy, roundish heart-shaped, serrated, on long, thick stalks. Flowers from March to May, clear rose, large, in clustered panicles.

The variety *purpurea* has very large thick and leathery leaves, and is a very strong grower. It has large and showy deep purple flowers.

Several more or less distinct and pretty hybrids have been raised between *S. cordifolia* and *S. purpurascens*.

Culture and Propagation.—This species flourishes in ordinary good and well-drained garden soil in open sunny

situations. The plants like plenty of water during active growth and during the summer months. Owing to the glossy texture of the foliage, they stand the smoke and dirt of town gardens well, although they are often very much neglected in such places. Increase may be effected by dividing the plants in early autumn or in spring. Seeds may also be sown as soon as ripe, as recommended above in the general instructions under Saxifraga.

S. coriophylla.—A sturdy, ornamental, silvery species, 3 in. high, native of the Alpine regions of N. Albania. Leaves in rosettes, entire, oblong, convex and keeled beneath, with 5-7 pits or depressions on the margin. Flowers in early spring, large, pure white; petals obovate-oblong, with 3 straight veins. Near *S. Rocheliana*, and now considered to be a variety of it.

Culture &c. as above for *S. burseriana*.

S. cortusæfolia.—A stemless Japanese species with roundish heart-shaped or reniform leaves, 2-3 in. wide, 5 or more lobed, bright green, fading to red or reddish-brown in autumn. Flowers in autumn, white, spotless, in panicles 7-8 in. long.

Culture &c. as above indicated in the general instructions under Saxifraga. Warm sunny positions in well-drained gritty loam suit this plant best. In the colder parts of the kingdom a little protection in severe winters may be necessary. Increased by seeds or division.

S. Cotyledon.—A fine silvery European species, 1-2 ft. high. Leaves in large rosettes, flat, fleshy, spoon-shaped, margined with finely pointed teeth. Flowers in early summer, white, in a large elegant pyramidal panicle 6 in. to a yard high. *S. nepalensis* and *S. pyramidalis* are merely strong-growing varieties of this species, and *S. montavoniensis* has white flowers with red calyx and stamens.

Culture &c. as above for *S. Aizoon*. This species will flourish almost anywhere on old walls, ruins &c. in warm sunny positions. The variety *pyramidalis* however is somewhat tender in the colder parts of the kingdom, and requires protection in winter. It makes a beautiful pot plant.

S. crassifolia (*Megasea crassifolia*). A stout Siberian plant with thick, woody

roots and large, fleshy, oval or obovate leaves, very blunt, smooth, and serrulated. Flowers from March to May, red, large, in clustered panicles about 9 in. high.

Culture &c. as above for *S. cordifolia*.

S. crustata.—A native of the chalky Alps with rosettes of blunt linear leaves with minutely crenate margins, and having the upper surface coated with a whitish or grey-green limy powder, and washed with rose or purple beneath. The hairy flower stalks carry 3-6 flowers which are usually white but sometimes spotted with purple-red at the base of the obovate petals.

Culture &c. as above for *S. Aizoon*.

S. cuneata.—A loosely tufted species, native of the Spanish mountains, with leathery spoon-shaped or linear-lance-shaped leaves somewhat clammy beneath, and having three large teeth or lobes. The white flowers are borne in loose panicles about July, and have obovate oblong petals.

Culture &c. as above for *S. ajugæfolia*, p. 417.

S. cuneifolia.—A tufted species native of the mountains of Central and S. Europe. Leaves obovate wedge-shaped, serrate, rather leathery, deep green above, reddish beneath. The flower stalks are 4-6 in. high, and bear a small panicle of white flowers, with a yellow centre, in May and June.

Culture &c. as above. This species likes a warm moist position among the rocks and stones in the rock garden. There are several varieties of it, the best known being *apennina* with smaller leaves and flowers. The plants are useful for the lower portions of the rock garden, and are readily increased by seeds or division. See also general cultural instructions under Saxifraga, p. 415.

S. cuscuteformis.—A Japanese species 6 in. high. Lower leaves thickish, roundish or ovate, deeply or wavy toothed. Flowers in summer, white, on branched panicles.

Culture &c. as above for *S. cortusæfolia*.

S. Cymbalaria.—A distinct Caucasian annual, with brown-striped, kidney-shaped, crenately lobed leaves. Flowers from early spring to autumn, bright yellow, in dense masses, on numerous weak straggling stalks. *S. Sibthorpi*, from Greece,

and also having yellow flowers, is very similar.

Culture &c. as below for *S. huetiana*.

S. diapiensoides.—A densely tufted plant $1\frac{1}{2}$ in. high, native of the Alps of Switzerland, Dauphiny, and the Pyrenees. Leaves linear, erect, keeled, with cartilaginous margins, fringed at the base, 1-2 perforated dots at the apex, and packed into dense cylindrical rosettes. Flowers in early summer, white, bell-shaped, 3-5 in a terminal head on leafy stems.

Culture &c. as above for *S. burseriana*.

S. diversifolia.—A Himalayan species, 6-18 in. high. Lower leaves stalked, 1-2 in. long, ovate or heart-shaped, acute; upper one stalkless. Flowers in July, yellow, $\frac{1}{2}$ - $\frac{3}{4}$ in. across, obscurely spotted, arranged in loose clusters.

Culture and Propagation.—This species likes damp, cool, and well-drained soil, with plenty of light and air, but not exposed to the scorching midday sun. It may be increased by sowing seeds or by division as recommended above in the general instructions given under Saxifraga.

S. exarata.—A very variable species, native of the mountains of Central Europe, with rosettes of wedge-shaped 3-lobed leaves, and white or yellowish-white, or rarely rose or purple flowers in June and July. The variety *nervosa* has looser rosettes of sparsely hairy clammy leaves, roundish-oblong in outline, and deeply cut into 3-5 narrow linear lobes. The milky-white flowers have obovate petals as in the type.

Culture &c. as above for *S. ajugæfolia*, p. 417.

S. flagellaris.—A Caucasian species, 3 in. high, with thread-like runners issuing from beneath the upper whorl of leaves and rooting at the tips. Leaves obovate, spoon-shaped; upper ones rather hairy. Flowers from April to July, yellow, on erect, simple, glandular-downy stems.

Culture and Propagation.—This plant likes a gritty loam and damp shady parts of the rockery. It is easily increased by the runners.

S. florulenta.—A very pretty species, native of the Maritime Alps. The deep green, spoon-shaped leaves, with bristly edges towards the base, are 1-2 in. long, and form rosettes often over 6 in. across. The beautiful rosy-red or lilac flowers

are borne on more or less hairy stalks in narrow clusters in early summer.

Culture &c. as above for *S. Aizoon*.

S. Fortunei.—A pretty Japanese species, with the habit of *S. cortusæfolia*. Leaves reniform, heart-shaped, lobed and laciniately toothed. Flowers late in summer, white, in erect panicles; petals very unequal, edges finely toothed.

Culture &c. as above for *S. cortusæfolia*. This plant requires protection in severe winters.

S. geranioides.—A Pyrenean species, 6 in. high. Lower leaves slightly hairy, roundish kidney-shaped palmately 3-cleft, the side lobes 2-cleft, entire or toothed. Flowers in July, white, numerous; petals obovate-oblong, clawed.

Culture &c. as above for *S. ajuga-folia*, p. 417.

S. Geum.—A pretty Pyrenean Saxifrage with rosettes or whorls of roundish or kidney-shaped toothed or crenate leaves, hairy above, smooth and often reddish beneath. The small blush-white flowers, dotted with red, appear in May and June, and are borne in erect panicles on stalks about 4–6 in. high.

The variety *dentata* (also known as *S. hirsuta*) has the hairy leaves deeply and prettily toothed, and pale green beneath, and the white flowers, dotted with rose, are borne on rather taller stems. The variety *elegans* has roundish heart-shaped leaves sharply serrate, and covered with hairs. The flowers are yellow spotted with purple. The variety *polita* differs in having smooth shining roundish heart-shaped leaves with crenate edges.

Culture &c. as above for *S. cuneifolia*.

S. globulifera (*S. granatensis*).—A native of the Spanish and Algerian mountains. It makes a turfy carpet of thickish ovate or spoon-shaped, bright green, entire or 3–5-lobed leaves, which assume a purple-red tinge during the winter months. The pure white flowers appear in May and June, 3–6 or more on a hairy stalk. The variety *gibraltarrica* differs in having the leaves more deeply divided into narrower lobes.

Culture &c. as above for *S. ajuga-folia*, p. 417.

S. granulata (*Fair Maids of France*; *First of May*; *Meadow Saxifrage*).—A pretty British and European species, 6–12

in. high. Leaves rather fleshy, kidney-shaped, lobed; lower ones on slender stalks, upper ones sessile, deeper and more sharply cut. Flowers in April and May, white, inclined or drooping, 1 in. across.

There is a double-flowered variety called *flore pleno*, the beautiful white blossoms of which are over an inch across, and sometimes having a stray petal tipped with carmine.

Culture &c. as above. This species likes a moist or boggy situation in the rock garden.

S. hieracifolia.—A European species, 1 ft. high. Leaves ovate oblong, remotely toothed, dilated at the base, smooth above, hairy beneath and on the edges. Flowers in summer, white, in erect branched panicles.

Culture &c. as above for *S. Clusi*.

S. Hirculus.—A distinct and pretty British and European species, 4–8 in. high. Leaves $\frac{1}{2}$ –1 in. long, lance-shaped or spatulate, in rosettes. Flowers in August, clear rich yellow, $\frac{1}{2}$ – $\frac{3}{4}$ in. across, with orange-red dots on the lower half of each obovate petal. The variety *grandiflora* has flowers quite 1 in. across.

Culture &c. as above for *S. diversifolia*. This species delights in moist or marshy spots in the rockery.

S. Hosti.—A native of S. Europe, 6–12 in. high. Lower leaves strap-shaped, obtuse, fringed; upper ones oblong, crenate-serrate. Flowers in May, white, with a few purple dots above the middle, 5–9 in a corymb. The variety *altissima* has broader leaves with serrate edges, and the white flowers have a greenish base and purple-red spots.

Culture &c. as above for *S. Aizoon*.

S. huetiana.—This pretty species is remarkable for being an annual or biennial and not a perennial. It is a native of moist and marshy spots on the Cilician mountains in Asia Minor, where it grows in the shade. It is closely related to *S. Cymbalaria*, and forms compact tufts 4–6 in. high of bright green slightly lobed roundish leaves. The numerous small bright yellow flowers are freely produced from May to July.

Culture and Propagation.—This species may be raised by sowing seeds when ripe in well-drained soil in cold frames, and keeping the seedlings under glass until mild weather the following

spring, when they may be transferred to moist shaded parts of the rockery. The seeds may also be sown in spring in the open air where the plants are to bloom, covering the seed-patches with a hand-light until the seedlings are well above the surface of the soil. But plants raised thus never attain the size and vigour of those raised from autumn-sown seed.

S. Huguenini.—A neat little perennial 1-2 in. high, native of the Swiss Alps. It has a tufted habit, and creeping stems clothed with oblong ciliate-toothed leaves. The solitary white flowers appear in early summer.

Culture &c. as above for *S. burseriana*.

S. hypnoides (*Dovedale Moss*; *Eve's Cushion*).—A pretty, deep green, mossy species, native of Britain and W. Europe. Leaves wedge-shaped, 3-5-cleft, smooth or more or less fringed with glandular hairs. Flowers from May to July, white, $\frac{1}{3}$ -1 in. across, on stalks 3-18 in. long. *S. decipiens*, *affinis*, *incurvifolia*, *hirta*, *gemmifera*, *platypetala*, and *Sternbergi*, are more or less distinct forms of this very variable species.

Culture &c. as above for *S. ajugæ-folia*.

S. imbricata.—A densely tufted Indian species 3 in. high, leaves small, channelled, ovate-oblong, keeled at the apex, hairy toothed on the edges. Flowers in June and July, white, solitary.

Culture &c. as above for *S. burseriana*.

S. integrifolia.—This is a hairy and clammy plant, native of the Rocky Mountains, and resembling *S. hieracifolia* and *S. virginianensis*. The deep green lower leaves are somewhat membranous, ovate oblong, very blunt, entire or slightly sinuate-crenate. The white flowers are borne on an erect naked scape about May and June.

Culture &c. as above for *S. Clusi*.

S. irrigua.—A native of Tauria 6-12 in. high. Lower leaves palmately 5-parted, upper ones 3-cleft, sessile. Flowers in summer, white, large, bell-shaped, in loose panicles.

Culture &c. as above for *S. granulata*.

S. juniperifolia (*S. juniperina*).—A distinct Caucasian species, with sharp pointed, oval-shaped leaves in dense, firm cushions. Flowers in summer, yellow or greenish-yellow, 6-10 on a spike.

Culture &c. as above for *S. burseriana*.

S. Kotschyi.—A pretty bluish-green species, native of Asia Minor, forming densely tufted rosettes $\frac{1}{2}$ - $\frac{3}{4}$ in. across, with small, obovate, blunt, apiculate leaves. Flowers in summer, yellow, in cymes at the ends of the short leafy stems. Requires sheltered sunny corners.

Culture &c. as above for *S. burseriana*, p. 418.

S. lactea.—A remarkable Siberian species 4-5 in. high, clothed with glandular down, and having tufts of wedge-shaped leaves cut into 3-5 bluntly oblong lobes, the upper leaves being cut into 3 linear blunt lobes. The white flowers, with obovate wedge-shaped petals, appear in June, and look very pretty against the bright green foliage.

Culture &c. as for *S. granulata*, p. 421.

S. latepetiolata.—A remarkable biennial Saxifrage, native of the Spanish mountains. It has strong branching stems 9-12 in. high, and dense rosettes of glandular hairy kidney-shaped leaves deeply cut into 3-5 coarsely crenate lobes, and having broad petioles. The white flowers, each $\frac{1}{2}$ in. across, are borne in crowded clusters.

Culture &c. as above for *S. huetiana*.

S. leucanthemifolia.—A pretty North American species 5-18 in. high. Leaves oblong wedge-shaped or spatulate, coarsely toothed or cut, tapering into a stalk. Flowers in summer, white, in a spreading corymbose or paniculate cyme; petals unequal, the 3 outer ones with a heart-shaped, dotted base.

Culture &c. as above for *S. Clusi*.

S. ligulata.—A handsome Nepalese plant 1 ft. high. Leaves obovate or rather heart-shaped, wavy, toothed, expanded at the base into a fringed sheath. Flowers from March to May, pale red, almost white, in forked panicles; petals broad, roundish. The variety *ciliata* differs from the type in having smaller leaves hairy on both surfaces, but it is a charming plant for sheltered nooks in the rockery. It may also be grown in cool conservatories, and will flower a week or two earlier as a result of the artificial protection.

The plant called *S. Schmidtii* seems to be identical with the ordinary form of *S. ligulata*.

Culture &c. as above for *S. cordifolia*.

S. lingulata.—A native of the Alps 1-1 $\frac{1}{2}$ ft. high. Leaves linear tongue-shaped,

channelled, warty, crenate, glaucous, fringed at the base, recurved at the apex. Flowers from May to July, white, dotted with rose; petals oval, conspicuously 3-nerved. The variety *cochlearis* has spoon-shaped, leathery leaves $\frac{1}{2}$ -1 in. long in tufted rosettes, and white flowers on purple-brown, glandular downy stalks.

Culture &c. as above for *S. Aizoon*.

S. longifolia.—A handsome Pyrenean species with linear-oblong, greyish-green leaves 6 in. long, thick, in dense rosettes, sometimes 1 ft. across, with cartilaginous, serrulate edges. Flowers in July, white, slightly dotted with red, in a close pyramidal cluster 1-2 ft. high.

Culture &c. as above for *S. Aizoon*.

This species may be planted between stones and does best in a position facing west or south-west.

S. luteo-viridis.—A densely tufted species 4-5 in. high, native of the Transylvanian mountains. Lower leaves more or less spoon-shaped, ciliate at the base. Flowers from June to August, yellowish-green, in cymose panicles.

Culture &c. as for *S. burseriana*.

S. macnabiana.—A beautiful tufted perennial 4-5 inches high, with lance-shaped serrate leaves having a somewhat powdery surface. The flowers are produced freely in May and June on somewhat hairy stalks, and are about three-eighths of an inch across, being rendered particularly attractive by means of the numerous rose or crimson speckles on the lower portion of the pure white roundish petals.

S. macnabiana was raised in the Botanic Gardens, Edinburgh, in 1875, and is believed to be a hybrid between the *pyramidalis* variety of *S. Cotyledon* and either *S. lingulata* or *S. Hosti*.

Culture &c. as above for *S. Cotyledon*.

S. macropetala.—A remarkable Tyrolean species more or less resembling both *S. biflora* and *S. oppositifolia*. The lower leaves are roundish wedge-shaped, the upper ones being somewhat ciliated and pitted. The deep lilac flowers, with broad elliptic petals, appear in April, and are rendered distinct by the pretty red anthers.

Culture &c. as for *S. oppositifolia*.

S. marginata.—A native of S. Europe with purplish stems 2-4 in. high. Leaves in dense rosettes, small, oblong, dotted on

the margins with incrustations of lime. Flowers in July, white, $\frac{1}{2}$ in. across, in small rather compact cymes.

Culture &c. as above for *S. burseriana*. This is one of the prettiest of the 'encrusted' Saxifrages.

S. maweana.—A beautiful tufted rock plant, native of Tetuan. Leaves 1-2 $\frac{1}{2}$ in. long, lower ones in loose rosettes, roundish kidney-shaped, 3-cleft to the middle, or with the side-lobes cleft; upper ones wedge-shaped, 3-cleft. Flowers in May and June, white, $\frac{3}{4}$ in. across, on erect stalks 4-6 in. long.

Culture &c. as above for *S. ajugæfolia*. Requires a damp shaded place in the rockery.

S. media.—A native of the Pyrenees 6-9 in. high, forming dense compact rosettes on the ground. Lower leaves imbricated, spatulate, strap-shaped, sharp or blunt; upper ones spoon-shaped, smooth except at the apex. Flowers in summer, pink, crimson, or purple, changing to deep blue when old. The variety *FredERICI Augusti* has small rosettes of narrow lance-shaped bright green leaves and numerous yellow flowers on short leafy stalks.

Culture &c. as above for *S. burseriana*.

S. mertensiana.—A somewhat downy N. American species with roundish heart-shaped hairy leaves, cut into 3-4 blunt or acute lobes. Flowers in early summer, white, borne on slender erect scapes in loose panicles.

Culture &c. as above for *S. Clusi*.

S. mixta.—A densely tufted hairy Saxifrage, native of the Pyrenees. The more or less obovate wedge-shaped leaves are cut into 3 blunt linear lobes, and are for the most part bright green. The milky-white flowers appear in July and August, and the roundish-obovate petals are sometimes veined with purple. The variety *iratiana* differs in having broadly obovate wedge-shaped leaves cut into 5-9 short and blunt linear lobes, while the white roundish petals have purplish veins.

Culture &c. as above for *S. ajugæfolia*.

S. muscoides.—A pretty Pyrenean species 2-3 in. high, forming a dense green carpet of smooth entire or 3-5-cleft leaves. Flowers in May and June, pale yellowish or purple, 1-10 on a stalk. The variety *atropurpurea* produces a mass

of deep red-purple flowers on stalks 1-2 in. high; the variety *pygmæa* and *crocea*, as well as the closely related *S. aromatica*, *S. exarata*, *S. pedemontana* and *S. Rhei*, are all more or less beautiful rock plants.

Culture &c. as above for *S. ajugæ-folia*, p. 417.

S. mutata.—A Swiss species 6-12 in. high. Leaves flat spoon-shaped, cartilaginously crenated, fringed with long clammy hairs. Flowers in summer, reddish-brown, with deeper coloured dots, and borne in panicles.

Culture &c. as above for *S. Aizoon*.

S. nivalis.—A British species with rather leathery, broadly spoon-shaped, crenate-toothed leaves, reddish beneath, $\frac{1}{2}$ -1 in. wide, stalks 1-2 in. long. Flowers in July and August, white, $\frac{1}{4}$ in. across, 4-12 in a capitate cyme 3-6 in. high.

Culture &c. as above for *S. Clusi*.

S. oppositifolia.—A handsome British species with creeping leafy stems 6-8 in. long. Leaves opposite, densely crowded, ovate or obovate, flat, blunt, ciliated. Flowers in April and May, bright purple, $\frac{1}{2}$ in. across, on short annual shoots. There are several varieties, among which the following may be noted: *alba*, white flowers; *major*, with larger flowers than the type; *splendens*, very bright coloured flowers; *pyrenaica superba*, a strong-growing variety with rosy-lilac flowers twice as large as those of the type. Other forms more or less distinct in size and colour are *pyrenaica maxima*, *p. rubra*, and *grandiflora*.

Closely related are *S. rudolphiana* with rosy-purple flowers usually one on a stalk, sometimes two; *S. biflora*, with deep blood-red or bright rose flowers; *S. Kochi*, flowers rosy-purple in twos or fours; and *S. retusa*, leaves short, dense, and firm, flowers purple, in May and June.

Culture and Propagation.—Being a native of the alpine regions of Wales and Scotland, as well as Europe, this species requires to be grown in well-drained gritty soil, composed of sandy loam and pieces of granite or other rock. As hot summers are usually unfavourable to it, the plants should be placed on slopes or banks of the rockery facing north, with plenty of light and air, and during the summer months should receive good supplies of water. When well grown they form dense carpets of green and look

very handsome when in bloom. They also make very charming pot plants for a cold greenhouse. Increased by seeds, division, or cuttings of the tips of the non-flowering shoots.

S. pallida.—A pretty little Saxifrage native of the Sikkim Himalayas, where it grows wild at an elevation of 13,000-17,000 ft. It forms flat rosettes of green spoon-shaped leaves, more or less toothed on the margin, and produces its white flowers, $\frac{1}{4}$ - $\frac{3}{4}$ in. across, in spring. It is remarkable for the persistence of the blunt elliptic petals during the ripening of the seed.

Culture &c. as above for *S. Clusi*.

S. peltata (*Umbrella Plant*).—This is probably the largest of the Saxifrages. It is found near streams in California, and has roundish peltate 6-10-lobed leaves 6-18 in. wide, on cylindrical, downy stalks 1-2 ft. long, the lobes being cut and sharply toothed. Flowers in April, white or pale pink, $\frac{1}{2}$ in. across; petals elliptic, blunt.

Culture and Propagation.—This species grows luxuriantly near the edges of ponds, streams &c. where its roots can reach the water; but it also flourishes in moist shady parts of the ordinary flower-border. The remarkable leaves, owing to the depression in the centre where the leaf stalk joins the blade, hold a considerable amount of water after a heavy rain, and during the autumn months they assume rich and effective red and brown tints. The plant may be increased by seeds and division as recommended in the general instructions under Saxifraga.

S. pensylvanica (*Swamp Saxifrage*). A Pennsylvanian species 1-2 ft. high. Leaves clustered, oblanceolate, obscurely toothed, 4-8 in. long, narrowed into short broad stalks. Flowers in May and June, greenish, small, many on an erect, downy, clammy scape.

Culture &c. as above for *S. Clusi*.

S. pentadactylis.—A densely tufted Pyrenean plant 3-6 in. high. Leaves with long compressed stalks, smooth, 5-cleft. Flowers in May and June, white, in loose panicles.

Culture &c. as above for *S. ajugæ-folia*, p. 417.

S. pseudo-sancta.—A tufted species native of the Balkan Mountains, with hairy stems and erect appressed linear awl-shaped leaves, a little broader and

ciliate at the base, and of a bright shining green when young. The citron-yellow flowers appear in spring or early summer.

Culture &c. as above for *S. burseriana*.

S. purpurascens (*Megasea purpurascens*).—A large-leaved handsome Himalayan species 6–12 in. high. Leaves obovate rounded, entire, 2–3 in. long, glossy green, sometimes obscurely sinuated, and margined with red. Flowers from April to June, purple, bell-shaped, about 1 in. across, and borne in dense, downy, glandular, corymbose panicles.

Culture &c. as above for *C. cordifolia*, p. 419.

S. pygmæa (*S. paradoxa*).—A Pyrenean species 1–2 in. high, with slender thread-like stems. Leaves lance-shaped, smooth. Flowers in May and June, yellowish, very small.

Culture &c. as above for *S. ajugæfolia*, p. 417.

S. rocheliana.—A pretty Austrian kind with tufts of smooth, tongue-shaped, white-edged leaves, fringed at the base, the upper ones pale green, with clammy hairs. Flowers in spring, white, large, freely produced in corymbose stems 3–4 in. high. *R. coriophylla* is very near this, and is practically a variety of it.

Culture &c. as above for *S. burseriana*.

S. rotundifolia.—A native of Austria, about 1 ft. high. Leaves kidney-shaped, coarsely and unequally toothed, the upper ones stalked. Flowers in May and June, dotted with scarlet; petals lance-shaped, acute, 3-nerved. The variety *taygetea* from Greece has the leaves 5–9-lobed, the lower ones stalked and hairy-edged, the upper ones linear or trifid. Other forms are *angulosa*, *heucherifolia*, *lasiophylla*, and *repanda*.

Culture &c. as above for *S. cuneifolia*.

S. Salomoni.—This is a pretty hybrid between *S. rocheliana* and *S. burseriana*, both of which have white flowers. Their offspring has mossy grey-green leaves from which arise purplish scapes 2–3 in. high, each bearing a solitary white flower about $\frac{3}{4}$ in. across in March and April.

Culture &c. as above for *S. burseriana*.

S. sancta.—A beautiful species, native of Greece, forming a dense carpet-like mass of deep green, lance-shaped, keeled leaves, fringed and finely toothed on the margins. Flowers in early spring and summer,

bright yellow, in a short dense spike an inch or two high.

Culture &c. as above for *S. burseriana*.

S. sarmentosa (*Aaron's Beard*; *Creeping Sailor*; *Mother of Thousands*; *Old Man's Beard*; *Wandering Jew*; *Pedlar's Basket*, &c.).—The common names of this distinct and pretty Chinese plant show that it is fairly well known. Leaves roundish heart-shaped, hairy, crenate-lobed, red beneath, mottled above; runners creeping, and ending in rooting offsets. Flowers in summer, white, 2 of the inner petals having a yellow spot, and the central one 2 scarlet spots at the base; the 2 outer petals large, flaccid.

The variety *minor* is merely a smaller growing form; *tricolor* is a handsome plant with green leaves beautifully blotched with creamy white and red, but too tender, I fear, for outdoor cultivation, except in shady spots in summer.

This species is usually grown suspended in pots or baskets to allow the runners and offsets to hang down, and is often seen in rooms or cottagers' windows, or in cool conservatories. As an indoor rock plant it is charming. It may also be grown outside in the mildest parts of the British Islands.

Culture &c. as above for *S. Clusi*.

S. scardica.—A pretty Macedonian Saxifrage forming dense and somewhat hairy tufts. The leaves are oblong acute stiffish, becoming lance-shaped acute upwards, of a bright grey-green, tinged with dull purple beneath. The white or pale rosy-red flowers appear in June and July on purple hairy stems in corymbose clusters.

Culture &c. as above for *S. burseriana*.

S. Stracheyi.—A strong-growing species 4–8 in. high, native of the Western Himalayas. Leaves with roundish stipular sheaths at the base, obovate wedge-shaped, 3–6 in. long, lobed at the base, irregularly toothed and fringed on the edges. Flowers in March, pink, $\frac{3}{4}$ –1 in. across, in a much-branched drooping panicle; petals obovate, spoon-shaped, or roundish. The variety *Milesi* has leaves 9–12 in. long, 4–5 broad, and white flowers. *Thysanodes* is somewhat taller, with obovate, deeply crenate-serrate leaves, hairy on both sides, especially beneath; flowers in April, white, small, in a slightly branched raceme. The variety *alba* and the plant called *S. afghanica*, with white flowers, seem to be

identical. *S. speciosa* is a pretty hybrid in this section with large rather heart-shaped leaves and large bright pink flowers.

Culture &c. as above for *S. cordifolia*.

S. tenella.—A native of the Alps, with rosettes of linear pointed leaves, fringed on the margins. Flowers in summer white, numerous, in a loose panicle.

Culture &c. as for *S. flagellaris*, p. 420.

S. tombeanensis.—A pretty Alpine Rockfoil, native of the Tyrol, and somewhat resembling *S. burseriana*. It has rosettes of small erect ovate lance-shaped leaves minutely serrulate on the margins, the upper ones becoming much narrower and pointed, and covered with glandular hairs. The bright red hairy stems bear 3-4 white flowers in April and May.

Culture &c. as above for *S. burseriana*.

S. trifurcata (*S. ceratophylla*).—A showy and strong-growing species, native of Spain, with dark green, deeply 2-3-parted leaves, forming compact, wide-spreading tufts, 3-8 in. high; segments awl-shaped, horny-pointed; stems reddish at the base, clammy. Flowers in early summer, pure white, in loose branched panicles.

Culture &c. as above for *S. ajugaefolia*, p. 417.

S. umbrosa (*London Pride*; *St. Patrick's Cabbage*).—A beautiful and well-known garden plant, native of the Kerry mountains round Killarney, and the Spanish Peninsula. Leaves in loose rosettes, roundish or broadly ovate, coarsely toothed or crenate, $\frac{1}{2}$ -2 in. wide, stalked. Flowers in summer, white, $\frac{1}{4}$ in. across, dotted with red, in paniced cymes 6-12 in. high. *S. Geum* (and its forms *elegans* and *gracilis*), *S. hirsuta*, are varieties or sub-species; other forms being *punctata* and *serratifolia*.

Culture &c. as above for *S. cuneifolia*.

S. valdensis.—A native of the S. of France, 3 in. high. Leaves dense, short, flat at the base, but more or less keeled at the apex, irregularly dotted above. Flowers in May and June, white, rather large, corymbose, on short hairy stalks.

Culture &c. as above for *S. burseriana*.

S. virginianensis.—A pretty N. American species 4-9 in. high. Leaves obovate or oval spoon-shaped, thickish, crenate-toothed, narrowed into broad stalks. Flowers from April to June, white, in more

or less clustered cymes. The variety *flore pleno* has compact double flowers. *S. elongata* is closely related but has more slender flower stems.

Culture &c. as above for *S. Clusi*.

TIARELLA (FOAM FLOWER).—A genus with 5 species of erect slender perennial herbs. Leaves usually radical, long-stalked, simple or 3-foliolate. Stipules small, adnate to the stalks. Racemes terminal, simple or compound. Calyx lobes 5, ovate. Petals 5, entire. Stamens 10. Ovary superior; styles 2, slender.

T. cordifolia (*False Mitrewort*).—A pretty border or rock plant native of N. America. Leaves heart shaped, sharply lobed and unequally toothed, hairy above, downy beneath, stem sending out runners after flowering. Flowers in April, white, small, starry, in great abundance.

Culture and Propagation.—This species grows well in ordinary soil, and is easily increased by dividing the rootstock in early autumn or spring. It likes a partially shaded situation in the rockery or border.

TELLIMA.—A small genus of more or less hairy perennials with roundish heart-shaped lobed or toothed leaves, and greenish or white flowers in racemes like the Tiarellas. Calyx tube bell-shaped, 5-toothed or lobed. Petals 5, entire, 3-cleft or pinnately divided. Stamens 10. Ovary half-superior; styles 2-3, short.

T. grandiflora.—A hairy perennial $1\frac{1}{2}$ -2 ft. high, with lobed and toothed leaves beautifully veined and tinted with bronzy purple like some of the Heucheras. Its greenish-yellow flowers are borne in erect racemes but are not particularly attractive.

Culture and Propagation.—This is the species best known, but there are others somewhat similar such as *T. Cymbalaria* and *T. parviflora* but not so desirable. The plants grow in tufts in any ordinary good soil, and may be increased by division in early autumn or spring.

MITELLA.—A small genus of perennials with long-stalked, heart-shaped lobed or crenate leaves, with membranous stipules adhering to the stalks. Flowers small, greenish, in long slender racemes. Calyx with 5 spreading lobes. Petals 5, 3-cleft or cut into thread-like

filaments. Stamens 10 or 5. Ovary superior. Styles 2, short.

Culture and Propagation.—These plants though not remarkable for their flowers nevertheless make handsome tufts in the rock garden, like the Heucheras, Tellimas, and Tiarellas. They flourish in sandy peat and loam and may be increased like their relatives by division in autumn or spring.

M. diphylla.—A pretty N. American rock plant 6-9 in. high with tufts of heart-shaped 3-5-lobed and toothed leaves and whitish-green flowers with finely divided petals, appearing in April and May.

Culture &c. as above.

M. pentandra.—Also a native of N. America, about 6 in. high with heart-shaped bluntly lobed leaves and yellowish-green flowers in May, the petals being divided as in *M. diphylla*, but only 5 stamens present.

Culture &c. as above.

HEUCHERA (ALUM ROOT).—A genus including about 20 species of thick-rooted annual or perennial herbs, often tall, hairy or glandular, with naked or few-leaved scapes. Lower leaves long-stalked, broadly heart-shaped or roundish, lobed or crenate. Stipules membranous, adnate to the leaf stalks. Flowers in spiked racemes or panicles. Calyx lobes 5, sometimes unequal. Petals usually 5, small, entire. Stamens 5, inserted with the petals at the mouth of the bell-shaped calyx-tube. Ovary almost inferior, styles 2, elongated.

Culture and Propagation.—The Heucheras thrive in any ordinary garden soil, except stiff clay. They are easily increased by division in autumn, or early in spring. They may also be increased by seeds sown in cold frames as soon as ripe, afterwards pricking the seedlings out into a prepared part of the border the following spring in mild showery weather. They are valuable for the rockery or the edge of the ordinary flower border in well-drained positions.

H. americana.—A N. American species 1½ ft. high, clothed with a clammy down. Leaves 5-7-lobed, toothed. Flowers in summer, reddish.

Culture &c. as above.

H. brizoides is a hybrid with leaves like *H. sanguinea* and masses of soft pink

flowers in summer. It is not yet well known but is well worth growing.

Culture &c. as above.

H. cylindrica.—A native of N. America, 1-1½ ft. high. Leaves deeply and roundly lobed, and fringed. Flowers in summer, greenish, rather large.

Culture &c. as above.

H. glabra.—A native of N.W. America 1 ft. high. Leaves sharply lobed, smooth, unequally and sharply toothed. Flowers in summer, white, small.

Culture &c. as above.

H. hispida (*H. Richardsoni*).—A hairy species from the mountains of Virginia and Carolina. Leaves roundish, 5-9-lobed. Flowers from May to July, veined with purple, on stalks 2-4 ft. high.

Culture &c. as above.

H. micrantha.—A N.W. American species 1-2 ft. high. Leaves bluntly lobed, crenate, with horned teeth and beautifully marbled with deep brownish-purple, which gives a very effective appearance in the rockery or border. Flowers in summer, yellowish, in loose panicles.

Culture &c. as above.

H. pubescens (*H. pulverulenta*; *H. ribifolia*).—A plant about 1 ft. high, native of the United States, covered with a powdery down. Leaves acutely lobed and toothed. Flowers in summer, pale red, large, variegated with yellow.

Culture &c. as above.

H. sanguinea.—A handsome perennial 9-18 in. high, from N. Mexico. Leaves heart-shaped rounded, 5-7-lobed, toothed and ciliated. Flowers from early summer to autumn, bright coral red—or almost scarlet in the beautiful variety *splendens*—more or less drooping on a downy, branched stalk, like small blood-red Lilies of the Valley. The variety *alba* has white flowers, but is not nearly so showy.

Culture &c. as above. This species is far superior as a garden plant to any of the other species, and looks well in either the rockery or border. It flourishes in well-drained ordinary garden mould, and may be easily increased by separating the crowns early in autumn.

H. villosa (*H. caulescens*).—A native of N. America. Leaves sharply 7-9-lobed. Flowers late in summer, violet, small, on rusty-haired scapes 1-3 ft. high.

Culture &c. as above.

TOLMIEA.—A genus closely related to *Heuchera* and differing in having only 3 stamens. The only species described below requires the same treatment as *Heuchera* and *Tiarella*, both of which names it bore at one time.

T. Menziesi.—A native of N.W. America, having stems 1-2 ft. high, with 3-5 hairy leaves, lower ones stalked, incised, lobed. Flowers in April, greenish, rather large, nodding in a slender elongated raceme, calyx purple-nerved.

Culture &c. as above for *Heuchera*. It flourishes in ordinary well-drained garden soil and may be increased by division or seeds.

PARNASSIA (GRASS OF PARNASSUS).

A genus with twelve species of elegant, very smooth, scapigerous herbs, with radical, ovate-kidney-shaped or oblong leaves, with stalks dilated at the base. Scapes angled, 1-flowered. Calyx lobes 5. Petals 5, entire or fimbriated. Stamens 5, hypogynous or perigynous, alternating with 5 more or less club-shaped and divided, glandular tipped scales or staminodes. Ovary superior or half inferior. Style 1, very short, with 3-4 stigmas.

Culture and Propagation.—*Parnassias* thrive in a moist peaty soil in the rocky, or in the bog-garden. They may be increased by division in early autumn, or in spring as growth is about to commence; or from seed sown as soon as ripe in cold frames, afterwards pricking the seedlings out into light soil when large enough.

Tribe II. FRANCOEÆ.—Scapigerous herbs with parts of the flowers in fours (tetramerous). Stamens 4 or 8.

FRANCOA (MAIDEN'S WREATH).—A genus with two or three species of Chilean perennials beset with glandular hairs or down, and with thick fleshy rootstocks. Leaves crowded, lyrate-pinnatifid, or pinnate, glandular-toothed, net-veined. Flowers in long, more or less erect or arching racemes. Calyx lobes, petals, and stamens 4. Ovary free, 4-angled or lobed.

Culture and Propagation.—*Francoas* thrive in a rich, light, loamy soil, but can be grown out of doors (except in summer) only in the very mildest parts of the country, and they should have dry sheltered positions on warm banks or borders. The spikes of flowers, often over 2 ft. long, are

P. asarifolia.—A very pretty North American plant, 6 in. high, with more or less kidney-shaped leaves and white flowers in summer.

Culture &c. as above.

P. caroliniana.—A native of North American swamps, 6-9 in. high. Leaves roundish below, ovate above. Flowers from July to September, white, netted with green or purple.

Culture &c. as above.

P. fimbriata.—A remarkable plant, 6 in. high, native of N. America. Lower leaves kidney-shaped, hollowed out at the base and lobed or divided. Flowers in July, white, petals obovate, clawed, fringed at the base.

Culture &c. as above.

P. nubicola.—A Himalayan species with elliptic, rather heart-shaped leaves. Flowers in summer, white, solitary, over an inch across, borne on 4-angled stalks 6-12 in. high, and having 3-lobed yellow staminodes.

Culture &c. as above.

P. palustris (Common Grass of Parnassus).—A lovely little bog plant, about 6 in. high, native of the British Islands. Leaves heart-shaped rounded. Flowers in summer, $\frac{1}{2}$ -1 in. across, white, with greenish pellucid veins.

Culture &c. as above.

P. parviflora.—A native of N. America, 6 in. high, with ovate leaves. Flowers in July and August, white, net-veined with pale purple or green.

Culture &c. as above.

excellent for cutting and last a long time. Seeds must be raised in a hotbed or greenhouse, and may be sown in early spring. Afterwards prick out separately into small pots and grow on until large enough for putting out or growing in larger pots. The plants may also be increased by dividing the rootstock in spring or early autumn.

F. appendiculata.—A lyrate-leaved plant 1-2 ft. high. Flowers in July, pale red, with a deeper spot at the base of each petal, in compact racemes on nearly simple scapes.

Culture &c. as above.

F. ramosa.—This species has a stem, and shortly stalked, usually decurrent

leaves. Flowers in July and August, white, loosely arranged on a much-branched scape.

Culture &c. as above.

F. sonchifolia.—A species about 2 ft. high, with short-stalked leaves, usually

decurrent below the basal lobes. Flowers in summer, purple or pink, often with a darker blotch near the base of the petals.

Culture &c. as above. Increased by seeds or division.

Tribe III. HYDRANGÆÆ. Shrubs or trees with opposite, exstipulate, simple leaves. Stamens often epigynous, 8, 10, 12 or more.

HYDRANGEA.—A genus with over 30 species of deciduous or evergreen shrubs or trees with entire serrate or lobed leaves. Flowers in large terminal corymbs, fertile ones small, sterile ones large and without petals. Petals 4 or 5, valvate. Stamens 8–10. Styles 2–4, free or united at the base.

Culture and Propagation.—In the milder parts of the country, and on rich warm, well-manured loam, Hydrangeas grow very well. Cuttings of the young and partially ripened shoots root readily in sandy soil in a shady place in summer or under glass in spring or autumn. Seeds are freely produced by most of the species, and these may be sown in cold frames as soon as ripe. The seedlings will probably not appear till spring, when they may be pricked out into light rich soil in warm shady positions.

North of the Thames Valley Hydrangeas can scarcely be regarded as a great success in the outdoor garden, but in Devonshire and Cornwall and the South of Ireland they attain luxuriant proportions. Positions which are partially shaded from the hot midday sun suit the plants best. A good mulching of well-rotted manure in autumn or winter will be of the greatest benefit to the plants and enable them to produce masses of fine foliage and blossom every season. The bushy species may be pruned in winter, cutting away the old wood, so that young vigorous shoots may appear in spring.

Some people are always trying to turn the white flowers blue by the addition of alum, iron &c. to the soil, and there is a great variation in shade owing no doubt to the chemical composition of the soil in which the plants are grown. Indeed the Hydrangeas of the *Hortensia* type are as variable in the colour of the flowers, although raised from cuttings, as if they were raised from seed.

H. arborescens.—A N. American shrub 4–6 ft. high. Leaves ovate, rather heart-shaped, upper ones lance-shaped, coarsely

toothed, pale and rather downy beneath. Flowers in summer, white, small, fragrant, nearly all fertile, in flattish corymbs.

Culture &c. as above. It is not a particularly showy plant owing to the majority of the flowers being fertile or perfect (i.e. having both stamens and pistil). It is, however, interesting as being the first Hydrangea cultivated in British gardens.

H. aspera.—A hardy Chinese shrub resembling *H. paniculata* in habit, and having lance-shaped ovate or almost ovate tapering leaves, with wavy and serrate margins. The upper surface is green, but the under surface is greyish-green, thickly covered with roughish hairs. The cymes of flowers appear in summer, the sterile ones being large and numerous.

Culture &c. as above.

H. chinensis.—A Chinese shrub 2–6 ft. high, with deeply toothed leaves 3–5 in. long, and small clusters of white flowers in summer. It is closely related to *H. virens*, but differs in the leaves being green on both sides and in the sepals of the sterile flowers being equal in size, and thicker, almost fleshy in texture.

Culture &c. as above.

H. hirta.—A compact shrub, native of Japan, 3–4 ft. high, with slender hairy branches, and ovate, serrate, Nettle-like leaves. Flowers in summer, white, numerous, nearly all fertile, and borne in terminal cymes 2–3 in. across. Not a showy species.

Culture &c. as above.

H. Hortensia (*Hortensia opuloides*). A beautiful Chinese shrub 2–5 ft. high, with broadly ovate, pointed, serrated, shining green leaves. Flowers from spring to autumn, white or bluish, in large corymbs or cymes, nearly all sterile, and resembling those of the Guelder Rose (p. 410).

There are numerous fine varieties of this species, the best being:—*japonica*, or *Lindleyi* as it is now called, with white or blue flowers tinged with red

and finely toothed; *Belzoni*, flowers white or blue with entire sepals, and *B. variegata*, with white blotched leaves; *Otaksa*, flowers flesh-coloured, handsome; *communis*, flowers deep rosy-pink; *stellata*, all the flowers sterile and double, pink, rose, or pale blue, changing to green with age; *Thomas Hogg*, a magnificent pure white variety, grown largely in pots for market work; *nigra* has pretty dark purple-brown stems; and *tricolor* has the leaves beautifully marbled with white and pale green, and edged with creamy yellow.

The variety *acuminata* has leaves slightly hairy on both surfaces, and bearded in the axils of the veins; the flowers are blue, but vary a good deal according to the nature of the soil in which the plants are grown.

Culture &c. as above.

H. involucrata.—A handsome Japanese shrub 6-10 ft. high with herbaceous stems and very large oval oblong or roundish double-toothed leaves sometimes nearly 12 in. long and 6-9 in. broad, which when young are covered on the under surface with a dense white woolly down. The flowers appear in summer in flat-topped or roundish clusters, and the inflorescence is remarkable for having large leafy bracts at the base where the branches are given off. The typical form has but a few large sterile flowers on the outer edge of the trusses, but in many forms which have been cultivated the sterile flowers are more numerous and vary in colour from rose to lilac, rose-pink, and even yellow, some forms having double flowers.

Culture &c. as above. This species likes warm, moist, and partially shaded situations. It is fairly hardy as far north as the Thames, but is better adapted for outdoor cultivation in mild southern and western parts of the kingdom.

H. paniculata.—This species attains a height of 25 ft. in Japan, its native country, forming a dense round head, and an upright trunk 6 in. in diameter. Leaves opposite or in threes, ovate oblong acute, downy, sometimes 5-6 in. long. Flowers in summer and autumn, pure white, in massive conical or cylindrical clusters 1 ft. long at the end of almost every shoot. There are several forms, the best known being *floribunda*, *grandiflora* and *minor*.

Culture &c. as above. To obtain the best results, this plant should be well

pruned in winter, and the soil well manured or mulched at the same period.

H. petiolaris.—A tall climbing or trailing shrub native of the Japanese mountains, where it grows in shady woods on the *Cryptomeria* (see p. 982), clothing the trunks to a great height, in the same way as the Ivy clammers up trees in this country. It has ovate or elliptic leaves, somewhat heart-shaped at the base, and produces flat corymbs of whitish flowers in June. Only a few of the outer ones are sterile and larger than the others. There are a few forms of this species, such as *scandens*, which has small heart-shaped or ovate leaves with long stalks; and *cordifolia*, which has distinctly heart-shaped leaves and entire or toothed sepals of the sterile flowers, rarely notched.

Culture &c. as above. Owing to its climbing character this species is best grown against a wall, or in the mildest parts of the kingdom it might be trained over or up old tree trunks in the same way as Ivy, or even over large boulders in partially shaded parts of the rock garden. This species is often erroneously called *Schizophragma hydrangeoides* in gardens.

H. pubescens.—A pretty Japanese shrub 4-5 ft. high, with deep green ovate serrate leaves tapering to a point and covered with a whitish down beneath. The leaf stalks and midrib are of a reddish-purple colour and look very pretty. The flowers appear in summer and are borne in a flat cyme with downy branches. Some of the outermost cross-shaped flowers only are showy and sterile, and over an inch across; they are white slightly veined with green, while the smaller fertile flowers have 3 styles.

Culture &c. as above. This species is quite hardy in the milder parts of the kingdom, but attains its finest proportions in the South and West.

H. quercifolia.—A very distinct and ornamental shrub native of Florida, 4-6 ft. high. Leaves large, ovate, about 6 in. long, lobed and toothed like a Plane rather than an Oak leaf, hairy and grey beneath, stalks and stems covered with a rusty down. Flowers in July, white, changing to greenish-purple and borne in flattish corymbs, a few of the outer blossoms being large and sterile.

Culture &c. as above.

H. radiata (*H. nivea*).—A N. American shrub 4–6 ft. high, closely related to *H. arborescens*, from which, however, it may be distinguished by the short dense whitish wool on the under surface of the leaves.

Culture &c. as above. This is fairly hardy in the Thames Valley, but is not a particularly showy species.

H. Thunbergi.—A Japanese dwarf shrub with slender branches, small ovate oblong leaves, and small cymes of flowers of a delicate peach blossom colour borne in summer, the outermost flowers only being sterile and not much more than $\frac{1}{2}$ in. across.

Culture &c. as above.

H. virens.—An elegant Japanese shrub 2–6 ft. high, with deeply toothed leaves 2–3 in. long, yellowish-green above. Flowers in summer, in small clusters; they are mostly sterile, and have 3 enlarged unequal sepals of a greenish-yellow colour. Very common near Nagasaki, but not yet grown in this country.

SCHIZOPHRAGMA.—A genus containing only one species:—

S. hydrangeoides.—A tall climbing deciduous Japanese shrub resembling *Hydrangea petiolaris*. The ovate heart-shaped tapering leaves, with coarsely toothed margins, are 2–4 in. long, and have long slender stalks. The white or flesh-coloured flowers appear in late summer or autumn in downy flat corymbose cymes, and resemble those of the *Hydrangeas* &c. in having the outer flowers larger and sterile. The fertile flowers have a top-shaped calyx with 5 teeth; 5 valvate petals, and 10 epigynous stamens inserted at the base of the disc.

Culture and Propagation.—This plant, sometimes called the Climbing *Hydrangea*, flourishes in good and well-drained garden soil, rich sandy loam with plenty of manure being preferred. In the mild southern and western parts of the kingdom it is quite hardy in ordinary winters, but in less favoured localities it is safer to give it the protection of a wall. New plants are obtained by inserting cuttings of the half-ripened shoots in sandy soil under a bell-glass, or better still in gentle bottom heat. When rooted they may be potted up and sprinkled overhead every day until well-established.

DEUTZIA.—A genus containing 7 species of roughish or downy shrubs with roundish opposite branches, and opposite, more or less deciduous, ovate or lance-shaped serrated leaves. Flowers axillary or terminal, in racemes or corymbs. Petals 5. Stamens 10. Styles 3 or 4.

Culture and Propagation.—*Deutzias* grow well in any fairly good soil in half sunny, half shady positions in borders or shrubberies; but they luxuriate in rich well-manured sandy loam. Out of doors *Deutzias* may be increased by layers in the autumn, or by division of the tufts. Cuttings of the ripened shoots 8–12 in. long may be inserted in the autumn like Currant cuttings (see p. 1095), or of the half-ripened shoots in early summer under a handlight.

Most of the kinds may be lifted in autumn if not too large, and grown in pots for conservatory decoration. They should not be forced with too much heat, otherwise the plants will take two or three years to recover from this exhausting process. The protection of a cold greenhouse, however, is quite sufficient to bring the plants into blossom some weeks earlier than those in the open air. Each year after flowering the shoots should be pruned and all old or useless wood cut out. A mulching of well-decomposed cow manure in autumn or winter will also be highly beneficial.

D. corymbosa.—A beautiful Himalayan shrub about 5 ft. high, with oblong or elliptic lance-shaped leaves, and forked corymbose panicles of white flowers.

Culture &c. as above.

D. crenata (*D. Fortunei*; *D. scabra*). *Pride of Rochester*.—A handsome Japanese shrub 4–8 ft. high, with ovate lance-shaped, somewhat bristly serrated leaves, rough to the touch. Flowers in summer, white. There are a few varieties, the best being *candidissima*, with a wealth of double snowy white flowers; *flore pleno*, flowers white, double, tinged with purple; and *purpurea-plena*, similar but more purple tinted. *Watereri* and *Wellsi* are supposed forms.

Culture &c. as above.

D. discolor.—A pretty Chinese shrub of recent introduction, and probably 6 ft. or more in height when fully grown. It has dull green lance-shaped toothed leaves $1\frac{1}{2}$ –3 in. long, the upper surface being very rough to the touch. The white

flowers each about $\frac{3}{4}$ in. across appear in May and June in compact corymbose clusters at the ends of the branches and also along the side shoots. The variety *purpurascens* has the flowers suffused with rosy-purple.

Culture &c. as above.

D. gracilis.—A Japanese shrub 1-2 ft. high. Leaves small, ovate, pointed, serrated. Flowers in April, white, numerous, in terminal racemes. There is a form called *foliis aureis* which has yellowish-green leaves.

Culture &c. as above.

D. Lemoinei.—This is a beautiful hybrid obtained by crossing *D. gracilis* and *D. parviflora*. It is intermediate between the two parents and flowers freely.

Culture &c. as above.

D. parviflora.—A beautiful Chinese shrub 3-6 ft. high, with ovate lance-shaped toothed and wrinkled leaves, and masses of creamy-white Hawthorn-like blossoms borne in April and May at the ends of the shoots.

Culture &c. as above.

D. staminea.—A Himalayan shrub about 3 ft. high. Leaves 1-2 in. long, oblong or elliptic lance-shaped, greyish downy beneath. Flowers in early summer, white, fragrant, in corymbs.

Culture &c. as above.

DECUMARIA.—A genus containing only one species here described:—

D. barbara.—An ornamental deciduous climbing shrub native of the S. United States, with round branches, and opposite stalked ovate-acute entire or slightly toothed leaves. The white sweet-scented flowers appear about June and are borne in corymbs at the ends of the shoots. The more or less bell-shaped calyx has 7-10 teeth. Petals 7-10, narrowly oblong. Stamens 20-30.

Culture and Propagation.—This plant may be grown against walls in the less favourable parts of the kingdom, or over tree-trunks, trellises, porches &c. in the mildest parts, in the same way as the Climbing Hydrangeas. It thrives in rich sandy loam in warm situations, and is benefited by a good mulching of manure in autumn or winter. It may be increased by cuttings of the half-ripened shoots inserted in sandy soil under a handlight during the summer months. The cuttings should be kept shaded from the sun and

sprinkled overhead occasionally until rooted. They may afterwards be given plenty of air and light, and be transplanted in spring.

PHILADELPHUS (MOCK ORANGE).

This genus contains about 12 species of deciduous ornamental shrubs with opposite roundish branches. Leaves opposite, entire or serrated, often clothed with starry down. Flowers axillary, solitary, or corymbose, often fragrant. Petals usually 4, rounded or obovate. Stamens 20-40. Styles 3-5, thread-like.

Culture and Propagation.—The Mock Oranges grow well in fairly good loamy soil. They flower on the wood of the previous year—a fact that should be remembered when pruning or cutting out the branches. They are easily increased from suckers or layers, and also from cuttings 8-9 in. long, inserted in the soil in autumn, and allowed to remain for about 12 months before transplanting.

The plants should always have plenty of air and sunshine and are more effective in beds or groups by themselves than mixed up with all kinds of trees in a shrubbery, where, owing to the absence of light and air, the plants soon become weak-stemmed and straggling.

In the autumn or winter a good top dressing of well-decomposed cow manure over the soil will be of great benefit to the roots and enable them to develop an abundance of blossom the following season.

P. coronarius.—This beautiful tree, 2-10 ft. high, is the well-known European Mock Orange. Leaves ovate pointed, serrate-dentate. Flowers from April to June, white, over 1 in. across, with a strong orange-like scent, and borne in racemes.

There are several fine varieties, the best being *aureus*, with beautiful golden foliage which, however, gradually becomes greener towards autumn; *argenteo-variegatus*, with more or less silvery leaves; *florè-pleno* (*Keteheri* or *primulaeflora*), with double flowers; and *nanus*, a bush about 2 ft. high, but not free-flowering; and *variegatus*, the leaves of which are edged with white.

Culture &c. as above. The type will flourish in almost any soil which is not too wet, and it will flower profusely year after year without the least attention, even in hard baked soil. It is, however, better to treat the plant well, as superior

results are obtained. The old wood should be thinned out in winter when necessary.

P. Coulteri.—A pretty hardy shrub, native of N. Mexico. It has slender drooping branches and ovate lance-shaped leaves with serrate margins, and covered with a white down beneath. The white flowers about 1 in. across appear in early summer singly at the ends of the branches.

Culture &c. as above. Requires the same treatment as *P. mexicanus*.

P. Gordonianus.—A native of N.W. America, about 10 ft. high, with ovate-pointed, serrulate leaves. Flowers in July, white, scentless, borne in racemes in great abundance.

Culture &c. as above.

P. grandiflorus (*P. speciosus*).—A handsome shrub 6–10 ft. high, native of the S. United States, with rather slender twiggy stems. Leaves ovate, pointed or nearly rounded, irregularly toothed, downy when young. Flowers in June, white, large, fragrant, 3–4 in. across, with roundish or broadly obovate petals and a bunch of yellow stamens in the centre. The variety *floribundus* is a very free-flowering form and the variety *laxus* may be recognised by its dwarfer habit, leaves covered with a hairy down beneath, and flowers either solitary or in threes. *P. inodorus* is a scentless form.

Culture &c. as above.

P. hirsutus.—A very pretty free-flowering species 3–5 ft. high, native of N. America. Leaves oblong-ovate, acute, toothed, hairy on both sides, white beneath. Flowers in June, white, solitary and in threes, covering the whole plant.

Culture &c. as above.

P. Lemoinei.—This is a beautiful hybrid between *P. coronarius* and *P. microphyllus*. Leaves lance-shaped, more or less pointed, slightly toothed, 3-nerved. Flowers in June, white, over 1 in. across, petals oblong-ovate, denticulate on the edges. The variety *erectus* is erect growing in habit; *Boule de Neige* (a cross between *Lemoinei* and the double-flowered form of *coronarius*), beautiful double white, fragrant.

Culture &c. as above.

P. Lewisi.—A North American shrub 6–8 ft. high. Leaves ovate acute, almost entire, with fringed margins. Flowers in

June, white, rather smaller than those of *P. hirsutus*.

Culture &c. as above.

P. mexicanus.—A beautiful Mexican Mock Orange 4–8 ft. high, with ovate acute or tapering leaves 2–2½ in. long, having a few distant teeth on the margins, and more or less downy according to age. The pure white circular flowers, over 2 in. across, with a conspicuous cluster of golden-tipped stamens in the centre, are borne singly in May and June at the ends of the slender and more or less hairy shoots.

Culture &c. as above. This species is too tender for the northern and bleaker parts of the kingdom, but in the mildest places in the south and west is practically hardy in ordinary winters.

P. microphyllus.—A dense bushy species about 3 ft. high, with ovate lance-shaped myrtle-like leaves ½–¾ in. long, somewhat 3-nerved, and slightly hairy beneath. Flowers in summer, white, fragrant, solitary or in threes, borne in great profusion. It is a native of Colorado, and although not many years in cultivation has already been used by the hybridist to produce the beautiful *P. Lemoinei* mentioned above.

Culture &c. as above. Grown in small groups on the grass or in front of taller shrubs it makes a very effective picture in the garden.

P. Satsumi (*P. japonicus*).—A slender free-growing Japanese bush 4–6 ft. high, with long narrow leaves, and white flowers about 1½ in. across, produced in pairs at the ends of the shoots in July.

Culture &c. as above.

PLATYCRATER.—A genus having only the one species described here:—

P. arguta.—A trailing or creeping deciduous Japanese shrub, with round branches and opposite short-stalked lance-shaped tapering leaves, deeply toothed on the margins and distinctly veined. The greenish-white flowers appear in summer, and are borne in corymbs at the ends of the shoots. The outer blossoms are sterile and larger than the others, as in the Hydrangeas, but much larger. The calyx has 5 triangular acute lobes. Petals 4, valvate. Stamens numerous, in many whorls. Styles 2.

Culture and Propagation.—This plant flourishes in ordinary garden soil and may

be used for clambering over boulders of rock or old tree trunks in open sunny situations. It may be increased by cuttings of the ripened shoots 8-9 in. long inserted in warm sheltered places in autumn, or of the half-ripened shoots placed under a handlight in summer and kept shaded and sprinkled overhead until rooted. Layers of the branches may also be made in late summer and autumn and detached the following spring if well rooted.

JAMESIA.—A genus with only one species, the description of which below contains the generic characters:—

J. americana.—A pretty dwarf deciduous shrub 2-3 ft. high, native of the Rocky Mountains of Colorado. Leaves opposite, ovate, serrated, white beneath. Flowers in June, white, about $\frac{1}{2}$ in. across, in terminal paniculate cymes. Calyx lobes triangular-ovate, sometimes 2-cleft. Petals 5, obovate. Stamens 10. Ovary conical. Styles 3-5, united at the base.

Culture and Propagation.—This shrub thrives in fairly good well-drained garden soil, and may be used in the borders or shrubberies, or in round beds on grass. It may be increased by seeds sown as soon as ripe in cold frames, or in spring in gentle heat. Cuttings of the mature shoots placed in sandy soil under a handlight in autumn will also root, and produce good plants by the following year or next.

Tribe IV. ESCALLONIEÆ.—Trees or shrubs. Leaves alternate, without stipules, simple, often leathery and glandular serrate. Stamens often equal to the petals in number.

ESCALLONIA.—A genus with 35 species of pretty evergreen shrubs, with white or red flowers in terminal panicles, or more rarely axillary. Calyx lobes 5, ovate or awl-shaped. Petals 5, linear spoon-shaped; claw erect, limb spreading. Stamens 5, epigynous. Ovary inferior; stigma capitate, 2-3-lobed.

Culture and Propagation.—In the milder parts of the country Escallonias are perfectly hardy, and in many places make beautiful hedges. In unfavourable parts of the kingdom, from the Thames Valley northwards, they are safer trained on a south wall. They grow in ordinary garden soil, and may be increased by cuttings of the half-ripened shoots, in sandy soil under a glass, or by layers or suckers. Many kinds ripen seed freely, and new plants can be obtained by sowing

CARPENTERIA.—Like the preceding, there is only one species in this genus:—

C. californica.—A handsome flowering shrub 6-10 ft. high, native of the Sierra Nevada, California. Leaves broadly lanceolate entire, 2-3 in. long, 3-nerved at the base. Flowers in June, white, 2-3 in. across, like the white Japanese Anemone, in racemose cymes. Calyx lobes 5-7. Petals 5-7, oblong obovate or roundish. Stamens numerous, inserted beneath the roundish flask-shaped ovary, looking very conspicuous with their golden anthers in the midst of the white blossoms.

Culture and Propagation.—This lovely shrub thrives in light warm soil, and requires protection except in the milder parts of the country. It may be grown in large pots, as a bush plant, and will thus be easy to place in a greenhouse in winter, or it may be trained on a south wall. It is increased from seeds sown in gentle heat or by layers made in late summer or autumn and detached the following spring when well rooted. Cuttings of the half-ripened shoots may also be inserted in sandy soil under a handlight and kept shaded and sprinkled overhead until rooted. Suckers from the base may also be detached with as many roots as possible, and if planted in good soil in showery weather in autumn will grow well.

them as soon as ripe in cold frames, or in spring in gentle heat, afterwards pricking the seedlings out and growing on under glass until large and strong enough for the open air.

E. illinita.—A Chilean shrub about 5-6 ft. high, with resinous branches and more or less oblong obovate leaves with crenulate margins, and somewhat clammy to the touch. The white flowers with long-clawed petals appear about August, in branched racemes or panicles at the ends of the shoots.

Culture &c. as above.

E. langleyensis is a graceful hybrid, more or less straggling in habit. Leaves about 1 in. long, obovate, toothed, shining green. Flowers in June, rose-purple, in the axils of the leaves for some distance

along the branches. The parents of this hybrid were *E. macrantha* with crimson-red flowers and *E. philippiana* with white ones.

Culture &c. as above.

E. macrantha.—A beautiful shrub 3-6 ft. high, native of Chiloe. Leaves ovate-elliptic, bluntish, serrate, shining, dotted beneath. Flowers in June, crimson-red, rather large. This is also known as *E. Ingrami* in some gardens.

Culture &c. as above.

E. montevidensis (*E. floribunda*).—A native of New Granada 10 ft. high. Leaves oblong, blunt, finely crenulated or entire. Flowers in July, white, in much-branched leafy corymbs at the ends of the branches.

Culture &c. as above.

E. organensis.—A handsome shrub 2-4 ft. high, native of the Organ Mountains, having rich red-brown stems and branches. Leaves oblong, blunt, deep glossy with red margins. Flowers in summer, deep rose.

Culture &c. as above.

E. philippiana.—A beautiful Valdivian shrub 3-5 ft. high, with rich green, rather spoon-shaped, serrated leaves, and densely crowded panicles of white flowers in July at the ends of the branches. This shrub is hardy in the Thames Valley, and makes a fine bush. The hybrid varieties *exoniensis* and *leucantha* are desirable on account of flowering till late in the autumn.

Culture &c. as above.

E. pterocladon.—A Patagonian shrub about 4 ft. high, remarkable for the peculiar winged branches, and small leaves. Flowers in July, white and pink, small, but in great profusion along the branches.

Culture &c. as above.

E. pulverulenta.—A hairy Chilean shrub 6-10 ft. high. Leaves elliptic, serrulate, rather clammy above when young. Flowers in June, white, in erect racemes at the ends of the branches.

Culture &c. as above.

E. punctata (*E. rubra punctata*).—A native of Chili 3-6 ft. high. Leaves bright green, elliptic acute, finely and often unequally toothed. Flowers in

July, deep red, in terminal corymbs. This plant may be easily distinguished from *E. rubra* by the stalked glands on the young shoots, flower stalks &c.

Culture &c. as above.

E. revoluta (*E. affinis*).—A Chilean shrub 3-6 ft. high, having softly downy branches and obovate acute leaves 1-2 in. long with toothed and recurved margins. The white flowers, each about $\frac{1}{2}$ in. long, are borne in late summer or autumn in branched racemes at the ends of the shoots.

Culture &c. as above.

E. rubra.—A rather smooth Chilean shrub 3-6 ft. high, clothed with glandular hairs when young. Leaves obovate-oblong, pointed, toothed, with resinous dots beneath. Flowers from July to September, red, 2-7 on a stalk.

Culture &c. as above.

ITEA.—A small genus of trees or shrubs with alternate, stalked, oblong or lance-shaped leaves with glandular toothed or crenate margins. Flowers small, white, in terminal and axillary racemes. Calyx more or less bell-shaped, with 5 ovate or awl-shaped persistent lobes. Petals 5, perigynous, linear, some what erect, spreading or reflexed. Stamens 5. Ovary superior or half superior, 2-celled.

I. virginica.—An ornamental deciduous shrub 6-8 ft. high, native of the E United States, with deep green oblong oval and minutely serrate leaves. The small white flowers appear in horizontal sprays in June, and very much resemble those of the Common Privet (p. 644). Owing to their great abundance they make a fine display against the deep green foliage.

Culture and Propagation.—This plant thrives in ordinary good sandy loam with a little peat or leaf soil added. It may be increased by seeds sown in cold frames as soon as ripe, or in spring in gentle heat. It may also be layered in late summer or autumn, and the suckers from the base may likewise be removed and transplanted in mild showery weather in autumn. Cuttings of the half-ripened shoots may also be rooted in sandy soil under a hand-light. In autumn plants, if not too large, may be lifted and grown in pots for conservatory decoration in spring.

Tribe V. RIBESIÆ.—Shrubs with alternate simple leaves. Stipules none or adnate to the leaf stalk. Flowers usually in racemes. Ovary inferior. Seeds immersed in pulp (as in Gooseberry).

RIBES (CURRANT; GOOSEBERRY).—A genus containing nearly 60 species of spiny or unarmed shrubs, with the characters of the tribe. Calyx-tube ovoid or spherical with a 4-5-parted limb; lobes usually coloured, erect or recurved. Petals 4-5, small, scale-like, inserted with the 4-5 stamens on the throat of the calyx. Styles 2, distinct or united. Berry oblong or round, pulpy.

Only the ornamental flowering shrubs belonging to the genus *Ribes* are described here. The Currant (*R. rubrum* and *R. nigrum*) and the Gooseberry (*R. Grossularia*) are dealt with in the Fruit section of this work (see pp. 1092, 1095).

Culture and Propagation.—The Flowering Currants thrive in any good garden soil, and are beautiful enough to deserve better treatment than they usually receive. In groups by themselves they are far more effective than when smothered in shrubberies. They are easily increased by layers, or by cuttings of the ripened shoots about 9 in. long in autumn, as in the case of the cultivated Currant (p. 1095). Seeds are ripened freely by many kinds, and may be sown as soon as ripe in cold frames, or in spring in gentle bottom heat. The seedlings should be pricked out and grown on until large enough to transfer to the open in mild showery weather in spring or autumn. To keep the plants in a good healthy condition and proper shape, a little pruning in winter may be practised, chiefly with a view to thinning out old or useless branches, and to prevent the centre of the bushes becoming choked with weak growths.

R. alpinum.—A compact-growing spineless shrub 3-5 ft. high, native of the Northern hemisphere, and often found growing wild in parts of Britain. Its slender branches are furnished with broadly ovate leaves $1\frac{1}{2}$ -2 in. across, somewhat 3-5-lobed and coarsely serrate, and more or less hairy on both surfaces. The yellowish-green flowers appear in April and May, and are not particularly attractive. The sexes however are distinct, the males and females being borne on separate bushes.

Culture &c. as above. Useful for

planting in poor soil and in shady places. There is a yellow-leaved variety (*aureum*), and also a dwarf form called *pumilum*.

R. americanum (*R. floridum*; *R. missouriense*).—A spineless N. American shrub about 4 ft. high. Leaves rather heart-shaped, 3-5-lobed, and doubly serrate, in autumn assuming a beautiful bright purple-bronze colour suffused with gold and crimson. Flowers in May, whitish, in drooping downy racemes.

R. aureum (*Buffalo Currant*).—A smooth, spineless N. American shrub 6-8 ft. high, with 3-lobed, irregularly toothed leaves. Flowers in April and May, golden-yellow, in long racemes. Fruit yellow, rarely black. The variety *præcox* flowers earlier than the type, and *serotinum* later, and finer. The variety known as *aurantiacum minus* is one of the best, its flowers being of a deep orange-yellow and sweet-scented. There are other less well-known forms, as *tenuiflorum*, and its variation *fructu-nigro*, the fruits of which change from yellow to red and then blackish-purple.

Culture &c. as above.

R. cereum (*R. inebrians*).—A pretty spineless N. American shrub 3 ft. high. Leaves almost round, bluntly 3-lobed, crenate, viscid. Flowers in May, white, tinged with pink, 3-5 on a drooping, downy raceme.

Culture &c. as above.

R. gordonianum (*R. Beatonii*; *R. Loudoni*).—A distinct and beautiful hybrid between *R. aureum* and *R. sanguineum*, the character of each being transmitted and mingled, the flowers being reddish tinted with yellow.

Culture &c. as above.

R. Lobbi.—A rare Californian shrub 3-5 ft. high, with prickly stems and lobed and toothed leaves like an ordinary Gooseberry bush, being also furnished with triple spines. The deep reddish-purple flowers appear in April and May, 1-3 on each stalk. The calyx lobes are spreading and thus give the flower a diameter of about an inch.

Culture &c. as above.

R. multiflorum.—A graceful shrub 5–6 ft. high, native of the Carpathian Mountains. Leaves heart-shaped, 5-lobed, hairy beneath. The greenish-yellow flowers appear in May, and are borne in graceful drooping racemes 4–6 in. long in great abundance, thus giving the shrub a distinct and even ornamental appearance.

Culture &c. as above.

R. sanguineum (*Flowering Currant*). A beautiful spineless shrub 4–10 ft. high, native of N.W. America. Leaves heart-shaped, 5-lobed, serrated, smoothish above, rather hairy beneath. Flowers in April and May, deep rose, in drooping, downy racemes.

There are a few varieties, but the deeper and more brilliant-flowered ones are best. The one called *atrorubens* or *splendens* is very fine; *albidum* has white flowers tinged with pink; *flore*

pleno (Burning Bush) has beautiful double flowers; *glutinosa* has pale rosy flowers, and rather clammy foliage; and *malvaceum* has lilac-tinted flowers in short dense racemes, and roughish hairy leaves with a white cottony down on the under surface. Other varieties are *atrosanguineum* and *carneum*.

Culture &c. as above.

R. speciosum (*Fuchsia-flowered Currant*).—A handsome Californian shrub, 6–8 ft. high, more or less hairy and prickly. Leaves somewhat 3-lobed, incised, crenate. Flowers in May, deep-red, or crimson, 4-parted, cylindrical, resembling some of the *Fuchsias* in appearance, drooping in small clusters, and remarkable for the much-protruding stamens.

Culture &c. as above. Increased by seeds or cuttings.

XLI. CRASSULACEÆ—Stonecrop and Houseleek Order

An order containing 400 species of usually fleshy herbs with opposite or alternate, sometimes united leaves, often crowded at the ends of the branches in rosettes. Stipules none. Flowers usually in cymes, hermaphrodite, regular. Calyx free, persistent, 3–5 rarely 6–30-parted. Petals 3–5, rarely more, free, or more or less united. Stamens as many or twice as many as the petals, perigynous, or nearly hypogynous, usually free. Carpels 3–5, rarely more, free.

GRAMMANTHES.—A genus with one or two species, natives of S. Africa, and having the characters here given under the following species:—

G. chloræfolia.—A pretty half-hardy annual 3–4 in. high, forming a dense tuft of ovate acute, fleshy leaves about $\frac{1}{2}$ in. long. Flowers in summer, orange-yellow at first, changing to red, with a distinct V-shaped mark at the base of each petal. Calyx bell-shaped, 5-cleft to the middle. Corolla tube with 5–6 spreading lobes. Stamens 5–6, adnate to the corolla tube. Carpels 5–6. *G. gentianoides* is similar, with a profusion of crimson or scarlet flowers tinged with yellow.

Culture and Propagation.—The plants thrive in dry parts of the rock garden and may be raised from seeds sown in heat about February or March. As the seeds are very minute they require scarcely any covering with soil. When the seedlings are well above the surface they may be pricked out into light rich sandy soil, and

will be fit for transferring to the open ground at the end of May or beginning of June. Warm, sunny, and fairly dry positions are necessary to grow this plant well. Stagnant moisture at the roots is fatal, and plenty of sunshine is essential to secure the full expansion of the blossoms.

COTYLEDON (NAVEL WORT).—A genus with which is now included the well-known *Echeveria*. The main characters of *Cotyledon* proper are: Calyx 5-parted. Corolla gamopetalous, with 5 reflexed lobes. Stamens 10, inserted on the corolla tube. Carpels 5, free. Natives of the Cape.

Echeverias differ chiefly in often having leafy sepals, and in being mostly natives of Mexico (one from Peru and another from Japan).

Culture and Propagation.—These plants thrive in ordinary well-drained garden soil. They may be increased by

seeds sown as soon as ripe under glass protection and in finely sifted soil. The more usual way, however, is to detach the offsets, which are freely produced, and insert them either in the open border until the end of autumn or in shallow boxes in sandy soil. In the case of *Echeveria secunda glauca*, offsets can be induced to form freely by cutting off the chief rosette of leaves, leaving the thick fleshy stems in the soil. In a short time all round the edge of the cut stems offsets will be produced and may be taken off and inserted in shallow boxes. The chief rosette if simply placed on the soil will in the meantime have taken root and begun to produce offsets as well. A shady border is the best place for carrying out these operations in July and August.

Where offsets are not readily produced each leaf (which, however, should be pretty well mature) may be slightly stuck into dry sand in pans or boxes. After a short time small plants will develop from the base of the leaves, and then they should be gently watered and grown on until large enough to put into pots singly or several in boxes or pans.

Seeds are freely ripened and may be sown in autumn or spring in cold frames, or in gentle heat in light and rich sandy soil. When the seedlings are old enough they may be pricked out a couple of inches apart, and when fully grown are available for the outdoor garden.

These plants, although not proof against hard frost, will stand the winter well in a cold airy frame, and can easily be protected from severe weather by mats.

The Cotyledons and *Echeverias* are chiefly used for edging flower borders from early summer till the end of autumn.

C. metallica (*Echeveria*).—A beautiful Mexican succulent plant, 1-2 ft. or more high, with a large rosette of broad obovate spoon-shaped leaves 6 in. or more across and of a beautiful purplish glaucous metallic hue. Flowers in summer, yellow, tipped with red, 30-60 in a loose clustered panicle.

Culture &c. as above.

C. secunda (*Echeveria*).—A beautiful edging plant, native of Mexico. Leaves in rosettes 3-5 in. wide, wedge-shaped, glaucous. Flowers during summer, red and yellow, on long curved stalks, very beautiful. The variety *glauca* has bluish-

white leaves; *glauca major* is a large-leaved form; and *ramosa* is a monstrosity with a flat stem covered with small, green, abortive leaves.

Culture &c. as above.

C. Sempervivum (*Umbilicus Sempervivum*).—A pretty hardy species 4-6 in. high, with rosettes of ovate, dull green leaves tinged with brown. Flowers in August and September, deep red.

Culture &c. as above.

C. spinosa (*Sempervivum spinosum*). A hardy Asiatic species about 1 ft. high. Lower leaves in rosettes, spoon-shaped, becoming lance-shaped and flattish upwards. Flowers in June, yellow.

Culture &c. as above.

C. Umbilicus.—A hardy British plant about 6 in. high. Lower leaves shield-like, roundish, crenated. Flowers in June, yellow. Useful for the rock garden or hardy fernery.

Culture &c. as above.

SEDUM (STONECROP; ORFINE).—A genus containing about 120 species of succulent, usually prostrate, annual or perennial herbs, sometimes tufted or mossy, with alternate opposite and whorled leaves, entire or serrate, rarely lacinated. Flowers in cymes, hermaphrodite, or 1-sexed by abortion. Calyx 4-5-lobed. Petals 4-5 (rarely 6-7), free. Stamens 8-10 (rarely 12-14), perigynous. Carpels 4-5, free or rarely united at the base.

Culture and Propagation.—Sedums thrive in almost any soil and in any situation. The dwarf mossy kinds are at home on rockwork, old walls, ruins, as well as in the border as edgings, or raised mounds. They are easily increased by seeds, cuttings, or division, new plants arising from the tiniest morsels of some of the plants when put on moist soil in a shady place, either in early autumn or in mild weather in spring.

For garden purposes it is unnecessary to describe the whole 120 species, but the following will be found a good selection.

S. acre (*Wall Pepper*).—A smooth British evergreen 2-4 in. high, with small, thick, alternate, stalkless leaves, ovate or nearly round. Flowers in early summer, yellow. *Aureum* is a fine variety with bright golden-yellow leaves in spring, but not quite so hardy as the type; *elegans* is a silvery-leaved, delicate form; and *majus*

is a robust one with flowers $\frac{3}{4}$ in. across. *Marveanum* is another form.

Culture &c. as above.

S. Aizoon.—A Siberian species 1 ft. or more high with smooth, rather angular stems. Leaves stalkless, alternate, $2\frac{1}{2}$ in. long, oblong lance-shaped, coarsely and irregularly toothed, with a prominent midrib. Flowers late in summer, yellow, $\frac{1}{2}$ in. across, numerous.

Culture &c. as above.

S. album (*S. formosum*; *S. neglectum*).—A pretty British evergreen with alternate, spreading, linear-oblong, blunt leaves $\frac{1}{2}$ in. long. Flowers in summer, white, nearly 1 in. across, on pinkish stems 4-6 in. high. The variety *brevifolium* has shorter and thicker leaves; *micranthum*, smaller flowers, and flattened leaves; and *teretifolium*, with blunt (instead of lance-shaped) petals and sepals and leaves rather rounded.

Culture &c. as above.

S. Anacamperos.—A glaucous evergreen native of Central Europe. Leaves roundish or obovate, blunt, apiculate, lobed at the base, and margined with red. Flowers in July, violet, numerous, about $\frac{1}{4}$ in. across, rarely produced.

Culture &c. as above.

S. anglicum.—A pretty little evergreen species, native of Britain, and seen best in a wild state in rocks and banks by the sea. Leaves ovoid oblong, $\frac{1}{8}$ – $\frac{1}{4}$ in. long, swollen at the base. Flowers from June to August, pure white or rose-tinted, $\frac{1}{8}$ in. across, on stems 2 in. high.

Culture &c. as above.

S. cæruleum.—A charming little annual or biennial from the Mediterranean region. Leaves tufted, $\frac{1}{4}$ in. long, oblong, blunt, pale green dotted with red. Flowers in July, pale blue, $\frac{1}{4}$ in. across, on stalks 2-3 in. high.

Culture &c. as above.

S. erythrostickum.—A handsome Japanese species, with erect greenish stems 1-1 $\frac{1}{2}$ ft. high. Leaves $2\frac{1}{2}$ in. long, concave, oblong, sinuate, obscurely toothed, tapering into short stalks, or sessile. Flowers in autumn, greenish flushed with pink, nearly $\frac{1}{2}$ in. across.

Culture &c. as above.

S. Ewersi.—A somewhat tender Siberian evergreen. Leaves opposite, stalkless, roundish, about $\frac{1}{2}$ in. wide,

entire or slightly sinuate. Flowers late in summer, pink or pale violet, numerous; petals dark spotted.

Culture &c. as above.

S. glandulosum.—A glandular hairy annual native of Spain, with simple or forked stems 2-6 in. high. Leaves scattered, sessile, $\frac{1}{2}$ to $\frac{2}{3}$ in. long, linear oblong, blunt, cylindrical. Flowers in June, pale reddish-purple, $\frac{1}{2}$ in. across.

Culture &c. as as above.

S. glaucum.—A pretty glaucous evergreen species, native of Central Europe. Leaves densely crowded, $\frac{1}{4}$ in. long, linear, glaucous, becoming reddish, tipped with translucent dots. Flowers in summer, pinkish-white, $\frac{1}{2}$ in. across, 6-parted. This species is also known as *S. dasypphyllum*. The variety *platypetalum* has 7-9 petals.

S. japonicum.—A pretty Japanese evergreen. Leaves scattered or opposite, rather reflexed, oblong spoon-shaped acute, channelled above, bright green. Flowers in summer, yellow, $\frac{1}{2}$ in. across.

Culture &c. as above.

S. kamschaticum (*S. selskyanum*). An evergreen species native of Kamtschatka, with green or purple branches 6-8 in. long. Leaves about 2 in. long, oblong obovate, deep green, toothed towards the apex, with minute warts on the edges. Flowers late in autumn, yellow, $\frac{3}{4}$ in. across, on stalks 4-6 in. high.

Culture &c. as above.

S. Lydium (*S. lividum*).—A pretty little species from Asia Minor. Leaves crowded, $\frac{1}{4}$ in. long, linear, roundish, greenish or tipped with red, lobed at the base, with minute pimples at the apex. Flowers late in summer, pinkish, less than $\frac{1}{2}$ in. across, on shoots 4-5 in. long.

Culture &c. as above. This species is excellent for edging slopes, footpaths &c., or for carpet-bedding.

S. Maximowiczii.—A Siberian Stonecrop with strong erect stems 1 $\frac{1}{2}$ -2 ft. high, furnished with alternate oval lance-shaped deep green leaves, the upper whorls of which have crenulate margins. The brilliant yellow blossoms appear in July in large flattish heads well above the foliage.

Culture &c. as above. An excellent plant for the rockery or border where it will flourish in rather dry sunny places for several years without much attention.

S. maximum.—A native of Europe and Asia with erect green or purple stems 1-2 ft. high. Leaves stalkless, stem-clasping, about 3 in. long, ovate acute, more or less heart-shaped, crenate-toothed. Flowers late in summer, whitish, on long stalks; petals spotted with red at the apex.

There are many forms of this very variable species, but *hæmatodes*—a Portuguese variety—is perhaps the best of them all. It has erect purplish stems 2-2½ ft. high, and purplish, oblong ovate, blunt, coarsely toothed leaves, about 5 in. long, and flowers as in the type. *Atropurpureum* is another deep coloured form.

Culture &c. as above.

S. populifolium.—A Siberian and N. American Stonecrop with rather woody branching stems 12-18 in. high, furnished with alternate stalked bright green leaves, ovate acute in outline, unequally toothed on the margins. The starry pink and white flowers with purple stamens appear from July to September in dense masses at the ends of the shoots.

Culture &c. as above. A good plant for the rock garden facing north or east. Increased by cuttings of the non-flowering shoots.

S. pulchellum.—A handsome species from the United States, with slender trailing branches 3-6 in. long. Flowers in summer, rosy-purple, ½ in. across.

Culture &c. as above.

S. reflexum (*S. collinum*; *S. virens*). A variable evergreen species, native of Britain, Europe &c., with trailing stems. Leaves in 6-7 rows, crowded into a conical mass, ½-¾ in. long, linear awl-shaped, roundish, swollen at the base, spreading or abruptly decurved. Flowers in summer, yellow, ¾ in. across, 4-8 parted, on stems 8-10 in. high. The variety *monstrosum* has flattened stems and leaves clustered on top as in the Cockscomb.

Culture &c. as above.

S. roseum (*Rhodiola rosea*). — *Rose Root*.—A pretty British plant with fleshy stems 6-18 in. long. Leaves 1-1½ in. long, glaucous, larger and more crowded upwards, obovate oblong acute, toothed at the apex. Flowers from May to August, ½ in. across, yellow or purplish. There are one or two varieties. *S. involucreatum* from the Caucasus is closely related. It

has flat roundish toothed leaves and flesh-coloured flowers produced from May to July.

Culture &c. as above.

S. rupestre.—Another British species with stout, loosely tufted, green or pinkish stems. Leaves ½-1 in. long, smooth, linear-lance-shaped acute, swollen at the base. Flowers in June and July, ⅓ in. across, golden-yellow, on leafy stems 6-10 in. high. The variety *monstrosum* is a rather slow-growing plant with flattened (fasciated) twisted stems, on the upper edges of which the glaucous leaves are borne like the flowers of the Cockscombs. *S. albescens*, *S. altissimum*, and *S. elegans*, all with yellow flowers, are closely related and are useful for the decoration of rockwork or for making edging to borders.

Culture &c. as above.

S. sarmentosum (*S. carneum variegatum*).—An elegant Chinese Stonecrop with creeping and rooting stems bearing sessile linear leaves either opposite or in threes, and of a bright green edged with white. The younger leaves are sometimes quite white. The golden-yellow star-like flowers, although individually insignificant, are produced in great profusion in cymes or panicles in June and July.

Culture &c. as above. An excellent plant for the rockery or for hanging pots &c. It is easily increased by cuttings of the ends of the shoots. In the colder parts of the country it requires protection in winter.

S. sempervivoides. — A very pretty downy species 4-8 in. high, from Asia Minor. Leaves in dense rosettes like the House Leek, 1 in. long, obovate wedge-shaped; those of the flower stem-clasping, greenish-red, oblong, acute. Flowers in July, bright red, over ½ in. across, on hairy stalks.

Culture &c. as above.

S. Sieboldi.—A pretty trailing Japanese species, hardy in most parts of the country but usually grown in greenhouses. Leaves in whorls of 3, sessile or nearly so, roundish, sinuate, bluish-green, with pinky edges, about ¾ in. wide. Flowers in August, about ½ in. across, pinkish, numerous; petals with a green spot on the back near the top. The variety *variegatum* has a central creamy white

blotch on each leaf. More tender than the type.

Culture &c. as above. This species, and its variety especially, is frequently grown as a pot plant, and may often be seen hanging in cottagers' windows. It is a graceful plant for the rockery or for hanging baskets &c.

S. spathulatum.—A pretty Stonecrop from British Columbia. It has spoon-shaped grey-green fleshy leaves and produces masses of golden-yellow flowers in summer.

Culture &c. as above. This species is quite hardy and looks effective as an edging or in the rock garden.

S. spectabile (*S. Fabaria*).—A vigorous Japanese species, 1-2 ft. high. Leaves opposite, in pairs alternately crossing, or in whorls of 3, 3 in. long, barely stalked, or the upper ones stalkless, ovate, blunt, or spoon-shaped, entire or slightly toothed. Flowers in September, pink, numerous, $\frac{1}{2}$ in. across, twice as long as the whitish sepals. There is a variegated form in which the leaves are heavily blotched with yellowish-white.

Culture &c. as above. This species makes an excellent pot and a good window plant, and will also succeed out of doors in shady as well as sunny places.

S. stoloniferum (*S. dentatum*; *S. denticulatum*; *S. spurium*).—A Caucasian evergreen with trailing, sometimes brown-dotted stems. Leaves $\frac{3}{4}$ -1 $\frac{1}{4}$ in. long, wedge-shaped, spatulate, coarsely toothed towards the apex, margined with translucent pimples. Flowers in July and August, pink or white, numerous, $\frac{3}{4}$ in. across, on reddish stalks about 6 in. long. *S. ibericum* is a form with small white flowers and ciliolate leaves.

Culture &c. as above.

S. Telephium.—A very variable British plant with stout green or red spotted stems 1-1 $\frac{1}{2}$ ft. high. Leaves 1-3 in. long, ovate or oblong, blunt, flat or concave, bluntly toothed or serrate. Flowers in July and August, $\frac{1}{2}$ in. across, rosy-white or speckled, in dense corymbose cymes.

Culture &c. as above.

SEMPERVIVUM (HOUSE LEEK).—A genus containing 40 to 50 species of thick fleshy herbs or undershrubs, varied in habit, often stemless and emitting young plants from the axils, sometimes caule-

scent and leafy. Leaves alternate, thickly fleshy, often in dense rosettes, and revolute. Flowers often in densely paniced cymes. Calyx 6-8 (rarely 5-) cleft or parted. Petals 6-8, free, oblong or lance-shaped, acute or pointed. Stamens usually twice as many as the petals, rarely equal in number. Carpels as many as the petals.

Culture and Propagation.—All the hardy House Leeks grow well in dry sandy soil, and are suitable for the rockery, on old walls or ruins, as edgings round beds or borders &c. They are easily multiplied by detaching the young plants produced round the base, or from seeds sown in finely sifted sandy soil, under glass as soon as ripe, or in spring. As soon as the young plants are large enough they may be pricked out into well-drained sandy soil, and it is safer to cultivate them in pots in cold frames for the first year before transferring them to their permanent positions in the open air.

S. arachnoideum.—A very distinct species native of the Pyrenees and Central Europe. Leaves oblong wedge-shaped, in dense rosettes, veiled with white cobweb-like hairs. Flowers in June, bright red, 9-12-parted, less than 1 in. across, on stems 3-4 in. long. The variety *Laggeri* is a large one with rosettes 1 $\frac{1}{2}$ in. across.

Culture &c. as above.

S. arenarium (*S. cornutum*).—A pretty Tyrolese species with rosettes of oblanceolate acute leaves, minutely ciliated on the edges, the outer ones tinged with brown, $\frac{1}{2}$ - $\frac{3}{4}$ in. long. Flowers in summer, pale yellow, $\frac{1}{2}$ - $\frac{5}{8}$ in. across, in dense heads, on downy stems 6-9 in. high.

Culture &c. as above.

S. arvernense.—A native of the French Alps, closely related to *S. calcareum*, but having smaller rosettes of oblong ciliate leaves, which are either smooth or slightly covered with glandular hairs. The floral stems are about 9 in. high, and bear bright rosy flowers in summer.

Culture &c. as above.

S. atlanticum.—A native of the Greater Atlas Mountains, with rosettes 2-3 in. in diameter of oblanceolate wedge-shaped, pale green leaves, slightly tipped with red-brown, fringed on the margins, the outer leaves 1-1 $\frac{1}{2}$ in. long. Flowers in summer, pale red, 1 in. across, 12-parted,

on stems about 1 ft. high with leafy red-brown bracts.

Culture &c. as above.

S. barbatus. — A distinct species 3-6 in. high, native of the Alps. Leaves in small rosettes, velvety, ciliated on the margins and furnished with a dense tuft of white, cobwebby hairs. Flowers in summer, bright rose, on stems 3-4 in. high, with red downy bracts $\frac{1}{2}$ - $\frac{3}{4}$ in. long. *S. piliferum* is closely related to this. It has smooth blue-green leaves slightly ciliated at the edges, and webbed with small white hairs. Flowers rosy.

Culture &c. as above.

S. Boissieri. — A garden species with dense rosettes, 2-3 in. in diameter, of wedge-shaped pointed leaves, over 1 in. long, ciliated with brown hairs. Flowers in July, pale red, very hairy, 1 in. across, 12-14-parted,

Culture &c. as above.

S. boutignyanum. — A Pyrenean species with rosettes 2-3 in. in diameter, pale glaucous green, often lined with red outside, brownish-red at the top, pale rose at the base. Flowers in summer, pale rose, with darker lines at the base, $\frac{3}{4}$ in. across, 12-14-parted, on stems 6-8 in. high.

Culture &c. as above.

S. Brauni. — A Tyrolean species with rosettes 1-2 in. in diameter. Leaves glandular downy, outer ones slightly tipped with purple, $\frac{3}{4}$ -1 in. long. Flowers in July, dull yellow with a green keel, $\frac{3}{4}$ -1 in. across, 10-12-parted, on downy stems 6-9 in. long.

Culture &c. as above.

S. calcaratum (*S. Camollei*; *S. italicum*; *S. juratum*; *S. Royeni*; *S. rusticum*; *S. Sequieri*). — A rather common plant with rosettes 3-4 in. across. Leaves 4 in. long, glaucous, distinctly tipped with red-brown, and edged with stiff hairs. Flowers in summer, dull reddish-white, 1 in. across, on tufted and branched stems over 1 ft. long.

Culture &c. as above.

S. calcareum (*S. californicum*). — A native of the chalky Alps of Dauphiny, with rosettes 2 in. in diameter. Leaves 1-1 $\frac{1}{4}$ in. long, very glaucous, tipped with red-brown, edged with stiff hairs. Flowers in summer, $\frac{3}{4}$ in. across, pale red with a greenish keel, densely fringed, 10-12-parted, on stems less than 1 ft. high.

Culture &c. as above.

S. fimbriatum. — A native of the European Alps with rosettes 1 1 $\frac{1}{2}$ in. in diameter. Leaves $\frac{1}{2}$ - $\frac{3}{4}$ in. long, green, strongly fringed with deflexed hairs, and tipped with purple-red. Flowers in July, bright red, 1 in. across, on densely glandular hairy stems 6-9 in. high.

Culture &c. as above.

S. flagelliforme. — Supposed to be a Siberian species. Rosettes 1-1 $\frac{1}{2}$ in. in diameter, the leaves pale green, fringed with short hairs. Flowers in June, bright red, over 1 in. across, densely glandular hairy outside, on stems 3-4 in. high.

Culture &c. as above.

S. Funcki. — A Tyrolean species with rosettes 1 $\frac{1}{2}$ -2 in. in diameter, surrounded by a circle of young ones on bright red stalks. Leaves green and smooth when old, fringed with dense hairs, and not tipped with red-brown. Flowers in July, rosy, nearly 1 in. across, on densely hairy stems 6-9 in. high.

Culture &c. as above.

S. glaucum. — A native of the Simplon Alps, with rosettes 2-3 in. in diameter. Leaves smooth, edged with hairs, faintly tipped with reddish-brown. Flowers in summer, bright red, 1 in. across, with deep purple filaments; on stems 6-9 in. high, hairy above.

Culture &c. as above.

S. grandiflorum (*S. globiferum*). — A native of the Alps, with rosettes about 1 $\frac{1}{2}$ in. in diameter, and numerous round, brownish-green offsets. Leaves downy, tipped with reddish-brown. Flowers in summer, 1 $\frac{1}{4}$ -1 $\frac{1}{2}$ in. across, pale yellow flushed with purple inside at the base, in dense heads on stems 3-4 in. high.

Culture &c. as above.

S. hirtum. — A native of Central Europe. Rosettes 1-1 $\frac{1}{2}$ in. in diameter, covered with soft glandular down, and fringed on the margins, outer ones faintly tinted with red. Flowers in June, pale yellow, on densely hairy stems 6-9 in. high.

Culture &c. as above.

S. Hueffeli. — A native of S.E. Europe, with rosettes 1 $\frac{1}{2}$ -2 in. in diameter. Leaves tinted with bright red-brown on the upper half, and margins fringed with stiff hairs. Flowers in August, straw-yellow with bright red-brown calyx when old. Flowering stems 6-8 in. high, very

downy, with reddish-brown leaves $\frac{3}{4}$ 1 in. long.

Culture &c. as above.

S. Lamottei.—A native of Central France. Rosettes 3-4 in. in diameter, smooth, ciliated, faintly tipped with reddish-brown. Flowers in summer, 1 in. across, pale pink, with bright purple filaments, on stems 1 ft. high.

Culture &c. as above.

S. mettenianum.—An Alpine House-leek with medium-sized rosettes of ciliated tapering leaves which assume a reddish tint, especially on the upper surface, in autumn. The flower stems are 4-6 in. high with rosy-white blossoms produced during the greater portion of the summer and autumn months.

Culture &c. as above.

S. Moggridgei.—Native of the Alps. Rosettes 2 in. across, green, smooth, with minutely ciliated margins, the stem leaves pale green and reddish. Flowers in September, $\frac{3}{4}$ in. across, red, on stout leafy stems 9 in. high.

Culture &c. as above.

S. montanum.—A Pyrenean species with dense rosettes over $1\frac{1}{2}$ in. in diameter. Leaves downy and glandular, ciliated, dark green. Flowers in June, bright mauve-purple, about 1 in. across, on leafy stems 6 in. high.

Culture &c. as above.

S. Pittoni.—A native of the Alps with medium-sized rosettes of velvety downy leaves fringed with hairs, and having a purple blotch at the tips. The yellowish flowers are borne on stalks 3-6 in. high during the summer months.

Culture &c. as above.

S. Pomelli.—A native of the Alps. Rosettes $1\frac{1}{2}$ -2 in. in diameter. Leaves hairy on both surfaces, the outer ones tinged with red. Flowers in July, bright

rosy-red, about 1 in. across, on densely hairy and leafy stems, 6-9 in. high.

Culture &c. as above.

S. ruthenicum.—A free-flowering Caucasian Houseleek with large rosettes of velvety downy leaves often fringed with silvery white hairs, and assuming a reddish hue in autumn. The rosy-white flowers are freely produced during the summer months on stems 6-9 in. high.

Culture &c. as above.

S. soboliferum (*Hen and Chickens Houseleek*).—An Austrian species with globose rosettes 1- $1\frac{1}{2}$ in. across, with numerous new ones attached by a thread-like stalk. Leaves minutely ciliated, the outer ones tinted with bright red-brown. Flowers in summer, pale yellow, about 1 in. across, on strong stems 6-9 in. long, quite hidden by the leaves.

Culture &c. as above.

S. tectorum (*Bullock's Eye; Common Houseleek; Jupiter's Beard; Sea-green*).—A well-known plant naturalised in but not a native of Britain. Rosettes 3-4 in. in diameter, pale green, ciliated, distinctly tipped with reddish-brown. Flowers in summer, $\frac{3}{4}$ -1 in. across, pale red, keeled with deep red; filaments bright purple. Flower stems about 1 ft. high, densely hairy. The variety *rusticum* (also known as *S. Requieni*) is distinguished from the type by its broad rosettes of blue-green leaves.

Culture &c. as above.

S. Wulfeni.—A native of Central Europe. Rosettes $1\frac{1}{2}$ -2 in. in diameter. Leaves somewhat glaucous, tipped with reddish-brown, with hairy edges. Flowers in summer, pale yellow, about 1 in. across, with bright mauve-purple filaments. Flower stems 6-9 in. long, densely hairy and leafy.

Culture &c. as above.

XLII. DROSERACEÆ—Sundew Order

A curiously interesting order containing about 110 species of annual or perennial glandular herbs; chiefly remarkable for their fly-catching propensities. The flowers are hermaphrodite. Calyx 4-8- (rarely 8-) parted or with free sepals. Petals 5, usually hypogynous, free or united at the base. Stamens 4-20, hypogynous or perigynous.

Except in botanic gardens, plants of this order are rarely cultivated, and even then they are not always seen in a happy condition. Where there is a

moist boggy corner in the rock garden, some of the Sundews like *Drosera rotundifolia* may be tried; also the Venus's Flytrap *Dionæa muscipula* from N. America, or *Drosophyllum lusitanicum* from Portugal; or during winter in cold frames in mossy and peaty soil.

XLIII. HAMAMELIDEÆ—Witch Hazel Order

A peculiar order containing 30 species of smooth or downy trees and shrubs, with usually alternate stalked leaves, simple entire or toothed, deciduous or persistent, stipulate. Flowers 1-sexed or hermaphrodite, usually united in dense heads. Calyx tube more or less adnate to the ovary; limb truncate or 5-lobed. Petals 4-8, rarely absent, perigynous or nearly epigynous, linear-spathulate or obovate, sometimes reduced to scales or deficient on one side. Stamens 4 or more, perigynous, usually inserted at the mouth of the calyx. Ovary inferior or half-inferior; styles awl-shaped, straight or recurved.

PARROTIA.—A genus with 2 species of trees or shrubs, having oblong or roundish deciduous crenate leaves, and large stipules. Calyx bell-shaped, with 5-7 persistent, leathery lobes. Petals none. Stamens 5-7. Styles 2.

P. persica (*Iron Tree*).—A beautiful small Persian tree about 10 ft. high, with ovate-oblong, deep green leaves which change to orange or yellow and crimson in autumn, and look very handsome. Flowers in February, chiefly conspicuous by the numerous crimson-tipped stamens.

Culture and Propagation.—Grown against a wall facing south or west, this tree is perfectly hardy, and thrives in ordinary good garden soil. It may be increased by layers in summer and autumn, or by seeds sown under glass.

FOTHERGILLA.—This genus contains only one species described below with the generic characters:—

F. alnifolia.—A pretty dwarf straggling deciduous shrub with crooked branches, 3-6 ft. high, native of N.E. America. Leaves obovate, obscurely or at the apex largely toothed, clothed with soft, starry down. Stipules twin, small. Flowers in April and May, white, sweet-scented, in dense spikes, before the leaves appear. Calyx tube bell-shaped, 5-7-toothed. Petals none. Stamens about 24. This species is now called *F. Gardenii*.

Among the varieties are *acuta*, with narrow, ovate acute leaves; *major*, with ovate-oblong leaves, somewhat lobed at

the base; *obtusa*, leaves obovate, crenate at the top, downy beneath when young; *serotina*, leaves oblong-acute, crenately toothed at the top.

Culture and Propagation.—This shrub and its varieties flourish in sandy peat and loam, in warm and well-drained situations, and may be trained on a wall like the Parrotia. It may be increased by layering the branches in late summer or autumn, or by means of seeds sown as soon as ripe in cold frames, or in spring in the same way.

CORYLOPSIS.—A genus with 3 or 4 species of ornamental deciduous Hazel-like shrubs. Calyx tube 5-parted. Petals 5, obovate spoon-shaped. Stamens 5, alternating with 5 truncate scales.

Culture and Propagation.—These peculiar plants require the same treatment as the Witch Hazels belonging to the next genus *Hamamelis*. They thrive in rich sandy loam or well-drained good garden soil and may be increased by aying the ripened shoots in autumn, or by sowing the seeds in cold frames when ripe, or in spring. The Corylopsis are valuable for their early-flowering properties in spring, and are quite as beautiful and useful when in blossom as the Witch Hazels.

C. himalayana.—A shrub about 6 ft. high, native of the Khasia Mts. and Bhotan. Leaves roundish ovate or acute, often lobed at the base, plaited, smooth above, silky or downy beneath. Flowers

in March, yellow or white, in drooping racemes at the ends of the branches.

Culture &c. as above.

C. pauciflora.—A Japanese species resembling *C. spicata* in habit, the colour and scent of its flowers; it is, however, a dwarfer plant with smaller leaves and fewer flowers in a raceme produced in March and April.

Culture &c. as above.

C. spicata.—A pretty Japanese shrub 3–4 ft. high. Leaves long-stalked, acutely heart-shaped, strongly feather-veined and serrated, somewhat hoary beneath. Flowers in February, pale yellow, scented like Cowslips, and issuing singly from a greenish-yellow bract, in drooping racemes 2–3 in. long.

Culture &c. as above.

HAMAMELIS (WITCH HAZEL).—A genus with only a few species of deciduous shrubs or bushes. Leaves roundish, unequal at the base, crenate-toothed. Calyx 4-parted, persistent. Petals 4, elongated linear, persistent, or absent in the female flowers. Stamens 4, alternating with 4 scales. Styles 2, short.

Culture and Propagation.—The Witch Hazels thrive in a moist sandy loam and are very effective as winter-flowering shrubs when grown in masses or beds by themselves. They are increased by layers chiefly, but also from seeds sown when ripe in cold frames, or in spring; and by grafting on stocks of *H. virginica* raised from seeds.

H. arborea.—A pretty Japanese tree 15–20 ft. high. Flowers in winter from December to February, while the branches are still in a leafless state; petals twisted, clear, rich, primrose-yellow; calyx deep claret.

Culture &c. as above. This is one of the most charming and conspicuous flowering shrubs in bloom during the dull months of the year. Its peculiarly twisted yellow flowers can be seen for a great distance, especially if several plants are grown in a bold group. They require but very little pruning; just cutting out any old or useless branches after flowering is over being sufficient. If the ground beneath is carpeted with Snowdrops, Scillas, Crocuses, *Eranthis hyemalis* &c. the bareness will be hidden and a good effect produced.

H. japonica.—Another Japanese shrub smaller than *H. arborea*, and with lemon-yellow flowers. It resembles *H. virginica* but differs in having larger flowers with dull purple calyx lobes.

Culture &c. as above.

H. mollis.—A pretty Chinese Witch Hazel of recent introduction. It has leaves much larger than the other Asiatic species, being 4–5 in. long and 2½–3½ in. wide, and also covered with a soft felt-like down on the under surface. The flowers appear in January and February and are borne on the leafless twigs. They resemble those of *H. arborea*, but are of a brighter yellow, although the petals are not so twisted.

Culture &c. as above.

H. virginica.—A N. American shrub about 6 ft. high, with obovate, sharply toothed leaves on short stalks. Flowers from October to February, rich yellow, in great profusion, on the leafless branches.

Culture &c. as above.

H. zuccariniana.—This is botanically only a variety of *H. japonica*, but very distinct from a garden point of view. It is very free-flowering, with pale yellow petals and a greenish-brown calyx.

Culture &c. as above.

LOROPETALUM.—A genus containing only the species described below with generic characters:—

L. chinense.—An ornamental evergreen shrub about 4 ft. high, native of the Khasia Mts. to China. Leaves dark green, alternate, oblong, entire, nerved beneath. Stipules membranaceous, deciduous. Flowers in autumn, white, 6–8 in a crowded head at the ends of the branches. Calyx tube 4-cleft. Petals 4, linear-elongated, somewhat twisted. Stamens 4, epigynous. Ovary half-superior; styles 2, awl-shaped.

Culture and Propagation.—This species thrives in light rich soil, and may be increased by seeds sown in cold frames when ripe or in spring; by cuttings of the half-ripened shoots in sandy soil under a handlight; or by layers in the autumn.

LIQUIDAMBAR.—A genus containing 4 species of ornamental, balsam-bearing, deciduous trees, with alternate, slender-stalked, palmately lobed, Maple-like glandulose-serrate leaves. Flowers

in small heads usually 1-sexed; very rarely somewhat hermaphrodite; male flowers often in racemes, without calyx and corolla. Stamens clustered, shortly stalked; females solitary, with a confluent calyx, and no petals, surrounded by scales.

Culture and Propagation.—Liquidambar-like a moist loamy soil and somewhat sheltered situations. New plants may be obtained from layers made in autumn and allowed to remain for about 12 months before detaching. Seeds (which have to be imported) take a very long time—perhaps 12 months—to germinate, but soaking in warm water may facilitate the process. When the young

plants are 6-9 in. high, they may be planted out in mild showery weather in spring.

L. orientalis (*L. imberbe*).—A large, slow-growing bush 10-20 ft. high, native of the Levant, with usually palmately 5-lobed, smooth leaves resembling some of the Maples.

Culture &c. as above.

L. styracifua (*Sweet Gum*).—A beautiful N. American Maple-like tree 30-50 ft. high in a wild state. Leaves palmately lobed, with the sinuses at the base of the veins, hairy. Flowers in spring, greenish-yellow.

Culture &c. as above.

XLIV. HALORAGEÆ

A natural order containing about 80 species of herbs or usually perennial aquatic or terrestrial undershrubs. Leaves opposite, alternate, or whorled, simple, entire or toothed, the submerged ones often pectinately pinnatifid. Stipules none, or adnate to the leafstalk as in *Gunnera*. Flowers usually axillary, solitary or clustered, sometimes in a raceme, spike, or panicle, or corymbose; hermaphrodite or 1-sexed, often minute, frequently incomplete. Calyx lobes and petals 2, 4, or none, the latter concave, deciduous, valvate or imbricated at the margins. Stamens 2-8, rarely 1 or 3, large, with short filaments. Ovary ovoid, oblong, or shortly cylindrical, flattened or 2-8-angled or ribbed, rarely 2-4-winged. Styles 1-4, with papillose or feathery stigmas.

GUNNERA (PRICKLY RHUBARB).—A genus containing 11 species of scapigerous perennial herbs with large, stalked, ovate or roundish heart-shaped, simple or lobed, crenate, thick, leathery, often wrinkled leaves, all springing from the creeping rhizome. Flowers greenish, minute, in dense spikes or branched panicles.

Culture and Propagation.—Gunneras thrive in rich moist loam and are effective when judiciously planted in sunny places on the edges of lakes, streams &c., where they can be sheltered by the surrounding vegetation from the violent winds. The huge Rhubarb-like leaves die down on the approach of winter. While dormant the rootstocks are best covered over with dry leaves until the spring, when the covering may be removed, so as not to weaken the young growths, although in mild winters this precaution is scarcely necessary. The old leaves themselves make excellent coverings for the crowns. Gunneras are increased by dividing the rootstock or

rather by detaching the thick bud-like shoots which form all round the base. Each shoot should be carefully planted in light rich soil in early autumn or in spring, and if started under the protection of cold frames so much the better.

Seeds may also be sown when ripe in cold frames or in gentle heat in spring, but it is rather a tedious process obtaining plants in this way as a rule. When well germinated the seedlings should be carefully pricked out, and it is best to grow them on in cold frames until they have become large sturdy plants. The following species are best known:—

G. manicata.—A noble-looking plant from the frosty regions of South Brazil. Leaves 4-7½ ft. in diameter, roundish heart-shaped and deeply lobed, and borne on stout stalks 4-6 ft. high.

Culture &c. as above. This species is perfectly hardy as far north as Aberdeen, with a slight protection of leaves in severe winters.

G. scabra.—A splendid Chilean species, with leaves 4-7 ft. across, borne on stout, prickly stalks 3-6 ft. long. Flowers reddish, small, very numerous, in a large, erect, club-shaped spike. A fine plant for sheltered places on the lawn or in grass. I saw a splendid specimen of

this species in a garden at Clovelly a few years ago, and it must have been about 16 or 17 ft. in diameter then and about 10 ft. high, although I believe it was sheltered by a shrubbery on every side except the north.

Culture &c. as above.

XLV. MYRTACEÆ—Myrtle Order

A large order containing 76 genera and about 1800 species of trees, shrubs, or undershrubs, very few of which unfortunately are hardy in our climate. Leaves simple, entire, or rarely obscurely crenate-serrate, opposite or alternate. Flowers regular or nearly so, hermaphrodite, or polygamously abortive. Calyx lobes 4-5, rarely 6-8 or 3. Petals 4-5, rarely 6, or fewer or none by abortion. Stamens numerous. Ovary inferior, rarely half-superior.

LEPTOSPERMUM.—A genus containing about 25 species of smooth or silky-haired small trees or shrubs, with small alternate rigid leaves. Flowers white, often polygamous, borne in twos or threes at the ends of the shoots, or solitary in the axils of the leaves. Calyx tube more or less broadly bell-shaped with 5 herbaceous or membranous segments. Petals 5, spreading. Stamens numerous, free.

Culture and Propagation.—Leptospermums are chiefly met with in botanic gardens, and are then usually grown in cool greenhouses. *L. scoparium*, however, described below, flowers profusely at Belvoir Castle, Grantham, the seat of the Duke of Rutland, and Mr. Divers says it was quite uninjured by 12° frost in January. It requires to be planted in a warm corner, and enjoys a soil composed of peat loam and sand in about equal proportions. Cuttings of the shoots may be rooted during the summer months under a handglass. Seeds, if obtainable, may also be raised in gentle heat in spring.

L. lanigerum.—A beautiful Australian shrub 3-6 ft. high with silky-haired ovate leaves about $\frac{1}{2}$ in. long. The beautiful white starry flowers, $\frac{3}{4}$ in. across, with roundish petals, appear from July to September and wreath the branches for about 6 in. Their general appearance and colour strongly remind one of the flowers of *Saxifraga burseriana* (p. 418).

Culture &c. as above. This species has been found perfectly hardy in the open air in various parts of the United Kingdom, notably in the north of Ireland and in Lancashire. It is a shrub that is well

worth growing, and although it was first introduced to cultivation as long ago as 1774 it is still practically unknown outside botanic gardens.

L. scoparium.—A beautiful New Zealand shrub 4-5 ft. high, with ovate mucronate leaves, which when rubbed between the hands give off a pleasant and fragrant odour. It produces masses of reddish-lilac flowers in January and February, about $\frac{1}{2}$ - $\frac{3}{4}$ in. across, which are particularly welcome at this season of the year out of doors.

Culture &c. as above.

EUCALYPTUS (GUM TREE).—A genus containing over 100 species of mostly Australian trees, some of which attain a height of over 400 ft. in their native country. They are recognised by their entire leathery often glaucous leaves, which in the young trees are opposite, becoming alternate on the same trees with age, and variable in shape. Peduncles axillary or bearing 3-15 flowers in an umbel rarely with only one flower. Calyx-tube pear-shaped or bell-shaped, truncate at the apex, entire or remotely 4-toothed. Petals enclosed in a leathery calyptra, or top-shaped capsule opening at the top. Stamens numerous, free.

Culture and Propagation.—Only comparatively few species of Eucalyptus are grown in this country, and these chiefly for sub-tropical gardening during the summer months. *E. globulus* is the most popular species for this purpose owing to its graceful habit and its beautiful glaucous, ovate-lance-shaped, curved leaves, which look beautiful waving in the breeze.

In the mildest parts of the south of England and Ireland some of the Eucalypti may live for years and attain a goodly size, but in less favoured parts they will not survive the winter. For subtropical bedding purposes, the imported seeds should be sown about August. They sprout freely, and the seedlings may be grown on during the winter in a cool greenhouse or cold frame. By this means they will be much larger and stronger for planting out in May or June than plants obtained from seeds sown in spring. The following are some of the best kinds for cultivation in the open air:—

E. coccifera.—This is a native of Tasmania and in the mildest parts of the kingdom it will form a small tree recognisable by its blue-green appearance. The leaves are mostly ovate lance-shaped, falcate, more or less tapering to a point, and from 4 to 6 in. long.

Culture &c. as above.

E. Gunni—the *Cider Tree* of Tasmania—is perhaps the hardiest of all the Eucalypti for this country. For several years a tree of it grew in Kew Gardens and reached a height of about 30 ft., but it was killed at last by the winter of 1894-5. It forms a bush-like tree, and the branches are furnished with ovate lance-shaped or elliptic leaves $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long.

Culture &c. as above.

E. urnigera.—This is another Tasmanian species which has been proved more or less hardy in the mildest parts of the kingdom in ordinary winters. It has dull green narrow lance-shaped acute leathery leaves 3-4 in. long, borne on twiggy branches with olive-green bark. At Whittinghame Gardens, Prestonkirk, N.B., there is a tree of this species which in 1887 was 60 ft. high, although it had been cut down to the ground by frost in 1860.

Mr. John Garrett, the gardener at Whittinghame, writes in reference to this particular plant:—‘The tree is still in vigorous health. Its height is now (1900) 75 ft. and girth of main trunk 12 ft. 7 in.

‘I have raised numerous seedlings from it. The first I raised was sown in September 1887, one of which is now 38½ feet high, and stem 1 ft. 10 in. This tree was twice transplanted, or it would doubtless have been much larger. We have planted quantities of it out in the woods also.

With regard to the variety, I cannot say positively what it is. Authorities have differed so much regarding it. For example, the late Mr. Bentham, and the late Professor Balfour, of Edinburgh Botanic Gardens, considered it to be *E. viminalis*. Sir J. Hooker names it *E. urnigera*, and Baron Müller called it *E. Gunni*. I have grown *E. Gunni* (true variety) here also, and must say that it resembles *E. Whittinghamii* more than any other sort I have seen, and yet there is the difference that while the leaves of *Gunni* are opposite or nearly so, those of *Whittinghamii* are distinctly alternate, and have each a stalk of considerable length. I have also raised plants of *E. urnigera*, but could see no resemblance here whatever. In fact, the sorts are totally distinct. I have tried a great many sorts here, including *E. coccifera*, and had them up to about 18 feet in height, but all were killed in the spring of 1895, except our own variety, which was almost uninjured. One other variety was killed to about 2 feet from the ground, viz. *E. vernicosa*, which broke away again, and is now a nice plant about 10 ft. high. My own opinion is that *E. Whittinghamii* is a natural hybrid. The seed was originally brought from Australia by Lord Salisbury.’

Culture &c. as above.

MYRTUS (MYRTLE).—A genus containing over 100 species of smooth, woolly, or downy shrubs, with opposite feather-veined leaves. Calyx lobes and petals 4-5. Stamens numerous, free. Ovary free. Fruit a berry.

M. communis (Common Myrtle).—A native of S. Europe 3-10 ft. high, with ovate, or lanceolate acute, deep green, shining leaves. Flowers in July, white, having the numerous golden-knobbed stamens much protruding. There are many varieties of the common Myrtle known as the Dutch, Italian, Roman, Rosemary or Thyme-leaved, Box-leaved &c., all beautiful and fragrant.

Culture and Propagation.—Except in the mildest parts of the country, the Myrtle requires the shelter of a wall. It likes a rich loamy soil with leaf mould, and during the summer months should not want for plenty of water. A good syringing every evening is very beneficial and gives the plants a beautiful fresh appearance and induces new growth. Sometimes the Myrtle is grown in pots,

and kept in ordinary living rooms during the winter, with an occasional watering and a sponging of the foliage with tepid water.

The Myrtle may be increased by cuttings of the ripe or almost ripe shoots inserted in sandy soil under a glass, or the lower branches may be layered in the autumn and detached when well-rooted the following year. The seeds when obtainable may also be sown as soon as ripe in cold frames, or better still in gentle bottom heat.

M. Ugni (*Eugenia Ugni*).—A beautiful Chilean shrub 4-6 ft. high with deep green shining ovate acute leaves, the margins of which are slightly reflexed. Flowers in summer, white, with numerous protruding stamens, and succeeded by roundish red or black berries, which have a pleasant taste and an agreeable aroma.

Culture &c. as above for the Common Myrtle.

XLVI. MELASTOMACEÆ

A large order containing 134 genera and 1,800 species, consisting chiefly of erect trees and shrubs, with opposite, exstipulate, paralld-veined leaves, and flowers in panicles, spikes, cymes or corymbs. The genus *Rhexia* described below is the only representative of the order hardy out of doors in the British Isles.

RHEXIA.—A genus including 7 species of erect branching herbs or undershrubs. Leaves oblong, shortly stalked, 3-nerved, entire or bristly serrulate. Flowers solitary or cymose, regular, hermaphrodite. Calyx tube oblong, bell-shaped, 4-lobed. Petals 4, obovate. Stamens 8, anthers with a pore at the apex, and a spur at the base. Ovary free, smooth, 4-celled.

Culture and Propagation.—Rhexias thrive in good peaty soil, and may be increased by dividing the rootstocks in early autumn or in spring. This operation however should not be performed more often than necessary, as the plants do not bear disturbance very well. In any case, only large clumps should be divided, and that as carefully as possible. They are excellent for massing in the front of borders, flower-beds &c., with taller plants as a background. They are all natives of Eastern N. America.

R. ciliosa.—A species 1-1½ ft. high, with smooth, 4-angled stems. Leaves about 1 in. long, ovate, 3-ribbed, and

bristly above. Flowers in July and August, purple, 1-1½ in. across, few on a leafy cyme.

Culture &c. as above.

R. mariana.—A bristly plant 1-2 ft. high, with round or 6-angled stems. Leaves lance-shaped acute, bristly, serrate, 3-ribbed. Flowers from July to September, purple, 1½-2 in. across, hairy outside.

Culture &c. as above. Owing to the brilliant crimson-scarlet tint assumed by the foliage of this species in autumn it should be planted in bold masses to secure a fine effect at that season.

R. virginica (*Deer Grass; Meadow Beauty*).—A bristly species 6-12 in. high, with 4-angled stems. Leaves ovate and ovate-lance-shaped, somewhat acute, sessile, bristly serrate, 3-5-nerved and covered with short bristly hairs. Flowers in July and August, bright purple or red, with a cluster of yellow-spurred stamens in the centre.

Culture &c. as above.

XLVII. LYTHRARIÆ—Loosestrife Order

This order contains about 250 species of trees, shrubs, or herbs of varied habit, often with 4-angled branches. Leaves usually opposite exstipulate. Flowers usually hermaphrodite, regular or rarely irregular. Calyx usually free, persistent, tubular, or bell-shaped, 3-12-lobed or toothed, valvate.

Petals as many as the lobes or teeth of the calyx, rarely fewer or none, often crumpled and clawed. Stamens definite or rarely numerous.

CUPHEA (CIGAR PLANT).—A genus with 90 species of herbs or small shrubs, often clammy and smooth-stemmed. Leaves opposite or whorled, rarely alternate. Calyx and tube elongated, ribbed, coloured, produced below into a spur, with 6 primary teeth, and 6 secondary smaller ones. Petals usually 6, clawed, the two upper ones usually larger. Stamens 11, the upper one missing, enclosed or protruding.

Culture and Propagation.—Cupheas are not strictly hardy plants, but as they are used so much for beds and borders in summer, they deserve notice here. They are increased by cuttings in brisk bottom heat in spring, or better still, seed may be sown in January or February in heat, and pricked out and potted on until planting-out time at the end of May. If grown in rich sandy soil they will be good plants by that time. The kinds mentioned below are best known. They should be planted in masses, each plant being 9 to 12 in. or thereabouts apart. In this way they will assist each other in producing a glowing effect.

C. eminens (*C. jorullensis*).—A greyish-green or whitish-looking Mexican plant about 2 ft. high with oblong lance-shaped acute leaves covered with down. The numerous flowers are borne in long terminal spikes in summer, and the velvety hairy calyx is of a bright orange-red colour.

Culture &c. as above.

C. ignea (*C. platycentra*).—A native of Mexico about 1 ft. high, with deep ruby stems, lance-shaped-pointed leaves, and bright scarlet, cylindrical flowers in July and August, with a black and white expanded limb, the whole flower resembling a miniature cigar with an ashy tip.

Culture &c. as above.

C. lanceolata.—A pretty branching Mexican annual 12-18 in. high, with alternate or opposite ovate lance-shaped downy leaves. The flowers appear in summer, and vary a good deal in colour from bright rose to purple or carmine and scarlet, the two upper and larger petals sometimes having a deep purple blotch at the base. There is a dwarf variety called

nana, which does not often exceed 9-12 in. in height.

Culture &c. as above.

C. miniata.—A Mexican perennial about 2 ft. high, with ovate-pointed leaves covered with white bristles. Flowers from June to September, pale vermilion. The variety *Llavea* has larger leaves, and bright purple, cylindrical, hairy tubes, with crumpled oblong petals, and woolly stamens.

Culture &c. as above.

C. silenoides.—A Mexican annual 12-18 in. high, closely resembling *C. lanceolata*. The conspicuous flowers appear from June to October, and have a rosy-purple calyx with deeper coloured stripes, and purple-brown petals, while the throat of the calyx tube is furnished with rosy-white hairs.

Culture &c. as above.

C. strigillosa (*C. cyanea*).—A much-branched Mexican species 12-18 in. high, with downy oval oblong acute leaves, and clusters of yellow and red flowers in summer. The clammy calyx is red at the base, and yellowish at the apex, while the petals are purple-red.

Culture &c. as above.

C. Zimapani.—A beautiful Mexican species about 2 ft. high. Flowers in autumn, deep rich purple, with a paler border.

Culture &c. as above.

LYTHRUM (LOOSESTRIFE).—A genus containing 12 species of smooth or downy herbs or undershrubs, with 4-angled stems. Leaves opposite, rarely whorled or alternate. Flowers in the axils of the upper leaves, solitary or cymose. Calyx tube cylindrical, 8-12-ribbed, straight, 4-6-toothed. Petals 4 6, obovate, sometimes unequal or none. Stamens 8-12, rarely fewer.

Culture and Propagation.—Lythrums are easily grown in ordinary garden soil, and may be increased by division in autumn or spring. If left undisturbed in a few years they spread over large areas and stifle other plants near them with their rather rank growth. The seeds are shed, and often masses of seedlings may be seen shooting up in spring all around the parent plant. It is necessary therefore

to keep the *Loosestrifes* within bounds in the rougher parts of the garden or by the banks of streams, lakes, ponds &c.

L. alatum.—A pretty half-shrubby N. American species 1-4 ft. high, with twiggy 4-angled branches. Leaves ovate oblong acute, rather lobed at the base, sessile, or nearly so. Flowers in summer and autumn, beautiful purple.

Culture &c. as above.

L. Salicaria (*Common Purple Loosestrife*).—A native plant 2-5 ft. high, with lanceolate leaves lobed at the base. Flowers in July, reddish-purple, in whorled leafy spikes, almost sessile, petals 6-7. There are two fine varieties, *roseum* and *superbum*.

Culture &c. as above. This handsome plant is excellent at the sides of streams, ponds &c.

L. virgatum.—A native of Siberia 2-3 ft. high, with lance-shaped leaves, narrowed towards the base. Flowers in summer, purple, in threes, distinctly stalked.

Culture &c. as above.

PUNICA (POMEGRANATE).—A genus with only 1 species, here described with the generic characters:—

P. Granatum.—A handsome deciduous tree 15-30 ft. high, native of Cabul and Persia, with oblong or lance-shaped entire leaves. Flowers from June to September, red, 2-5 together, almost sessile, near the ends of the branches. Calyx persistent, thick, fleshy, 5-7-lobed. Petals 5-7 inserted in the throat of the calyx, lance-shaped, crumpled. Stamens several. The double variety *flore pleno* is handsome; and *nana* is a much smaller plant than the type.

The imported fruit of the Pomegranate is well known. It is remarkable in being composed of 2 sets of carpels, one above the other, and the seeds are embedded in a pellucid pulp.

Culture and Propagation.—Only in favoured spots or on sheltered walls does the Pomegranate produce its flowers in this country, and very seldom its leathery skinned fruits. It thrives in a rich loamy soil, and when not trained against a south wall, or grown as a bush, it is sometimes treated as a pot or tub plant like Oranges, and kept in a greenhouse during the winter. It may be increased from seeds sown in gentle heat; by cuttings of the half-ripened shoots in gentle heat under a bell-glass; or by layers, suckers, or grafting, the latter process being reserved for fine coloured varieties.

XLVIII. ONAGRARIÆ—Evening Primrose Order

An order with over 20 genera and 300 species of annual or perennial scentless herbs, rarely shrubs, or trees. Leaves opposite and alternate, usually entire, dentate or serrate. Stipules none. Flowers usually hermaphrodite, regular, axillary and solitary, or spicate, or racemose, near the ends of the branches. Calyx-tube adnate to the ovary; limb, with usually 2-4 large, valvate, frequently coloured lobes. Petals often 2-4, rarely none, fugacious, twisted. Stamens 1-8, very rarely 5, 6, or 12. Ovary inferior, 1-6 very often 4-celled. Fruit various, capsular or berry-like.

EPILOBIUM (WILLOW HERB).—A genus with 50 species of erect, decumbent, or creeping herbs or undershrubs, having alternate and opposite, entire or toothed leaves. Calyx tube slender, scarcely produced beyond the ovary, linear, 4-angled or roundish; limb 4-parted, deciduous. Petals 4, obovate or orbiculate, erect or spreading. Stamens 8, alternately short and long. Ovary 4-celled; style thread-like, with an oblique club-shaped or 4-

lobed stigma. Capsule 4-angled, opening between the cells.

Culture and Propagation.—The kinds mentioned below are the only ones of any garden value. They thrive in any garden soil, and in any situation, and require to be kept in check, or they will soon choke choicer plants in a border or shrubbery. They may also be used with effect near water. Easily increased by seeds sown in the open border as soon as

ripe or in spring, covering the seed beds with lights in case of severe weather; or by division of the rootstocks in autumn or in spring. The following are a few of the best kinds:—

E. angustifolium (*French Willow* or *Rose Bay*).—A vigorous and rapidly spreading British plant 3-6 ft. high, with lance-shaped, wavy, Willow-like leaves, and spiked racemes of crimson flowers in July. There is a charming pure white variety.

Culture &c. as above.

E. Dodonæi (*E. Halleri*).—A European species 1 ft. high, with linear obscurely toothed leaves. Flowers in July, deep rose, large, crowded near the top of the branches.

Culture &c. as above.

E. hirsutum (*Codlins and Cream*). A British and European species 3-5 ft. high, covered with a soft clammy down, and exhaling a peculiar acid scent. Leaves opposite below, alternate above, ovate lance-shaped, hairy, toothed, half stem-clasping. Flowers in July, usually pale pink, sometimes white.

Culture &c. as above. This species naturally likes moist places, and may be used in masses at the edges of streams, ponds &c. for effect in the same way as the purple Loosestrife.

E. luteum.—A pretty N. American Willow Herb 6-9 in. high, with slender stems and broad, bright green leaves. The pale yellow flowers about an inch across appear in summer in clusters at the tips of the shoots.

Culture &c. as above. This species should be planted in a warm position sheltered from the north and east winds.

E. obcordatum.—A charming Californian species, low-growing, and suitable for moist well-drained parts of the rock garden. Leaves opposite, ovate, stalkless, glaucous, $\frac{1}{2}$ -1 in. long. Flowers in summer, bright rose-purple, large.

Culture &c. as above.

E. rosmarinifolium (*E. angustissimum*).—A pretty European species 2 ft. high, with linear obscurely toothed leaves like the Rosemary. Flowers in July, red, crowded near the top of the branches.

Culture &c. as above. This species makes elegant tufts and produces a grand effect when grown in masses. Owing to

its comparative dwarfness it may be utilised for the decoration of the rock garden, and grown in light rich sandy soil.

ZAUSCHNERIA (CALIFORNIAN FUCHSIA; HUMMING BIRD'S TRUMPET).—A genus with only one species:—

Z. californica.—A handsome downy branched shrub about 1 ft. high, native of California and Mexico. Leaves sessile, linear lance-shaped, downy, entire or finely toothed, lower ones opposite; upper ones alternate. Flowers in summer and autumn, bright red, in loose drooping spikes at the ends of the branches. Calyx tube linear, 4-angled, roundish or inflated at the base. Petals 4, obovate, 2-lobed. Stamens 8, alternately shorter. Ovary 4-celled; style with a 4-lobed stigma. Capsule linear, 4-angled.

Culture and Propagation.—In bleak localities this plant requires protection of the rootstock in winter by ashes, leaves &c., but it grows well in warm sheltered positions. The plants may be increased by sowing seeds in March in gentle heat, or by dividing the rootstocks about the same time. Cuttings of the non-flowering shoots may also be inserted in sandy soil under handlights in autumn, and again in spring, and this method may be adopted for perpetuating the finest coloured varieties. Of these there appear to be several, among them one named *mexicana*, which seems to be more hairy than the type, and with more brilliant flowers. The variety *latifolia* has broader whitish hairy leaves, and rather smaller flowers with a dull red calyx. This species has been found to flourish not only in good rich garden soil, but also in stiff clay, which was baked and cracked by the summer sun. Where the poor shy blooming varieties exist they are sure to cause disappointment, but there is nothing so fine as a good clump of the best forms.

CLARKIA.—A genus having a few species of smooth or hairy branching annuals, with alternate linear or lance-shaped, entire or toothed leaves. Flowers axillary, solitary, or in terminal racemes. Calyx tube linear, 4-angled; limb 4-parted. Petals 4-clawed, dilated, entire, or 3-lobed. Stamens 8.

Culture and Propagation.—Clarkias are very showy plants in the border and grow well in ordinary garden soil. They

may be raised from seeds sown out of doors either in spring or autumn, and when planted out to flower a distance of about a foot should be between them. They produce charming masses of colour in the flower border during the summer and autumn months.

C. elegans.—A pretty Californian annual with purplish stems, 1½ to 2 ft. high. Leaves ovate lance-shaped, smooth, dentate. Flowers in summer, rich crimson, with kidney-shaped, long-clawed petals. There are several varieties including pure white, rose &c. *Purple King* and *Salmon Queen* are two of the best double-flowered forms.

Culture &c. as above.

C. pulchella.—An elegant N. American annual, 1½-2 ft. high, with linear smoothish leaves, and large purple flowers in summer, with deeply 3-lobed petals. There are many single and double varieties of this species. The variety *alba* has white flowers. The one known as *integripetala* has entire instead of 3-lobed petals. There is also a dwarf *Tom Thumb* strain, the plants of which are shorter and more compact than the type.

Culture &c. as above.

GENOTHERA (EVENING PRIMROSE).

A genus containing about 100 species of herbs or small shrubs of variable habit. Leaves alternate, membranous, sessile or stalked, entire, toothed, lobed, or pinnatifid. Flowers axillary, solitary, sessile or stalked. Calyx tube linear or club-shaped, 4-angled, produced beyond the ovary, 4-lobed. Petals 4, obovate or obovate, barely clawed. Stamens 8, equal or alternately shorter. Stigma 4-lobed. Capsule membranous, leathery or woody, linear oblong or clavate, round, 4- or many angled and ribbed, or broadly 4-winged.

Culture and Propagation.—From June till the end of autumn *Genotheras* are among the most showy of hardy flowers, and they thrive in any fairly good sandy soil. They may be used in a variety of ways, in borders or shrubberies, mixed with other plants, or in beds by themselves, always favouring a warm sunny position. The annual and biennial kinds may be increased by sowing seeds in the open border in spring for flowering the same year; or in cold frames in autumn for blooming the following

year. In the case of perennial kinds, cuttings may be put in a cold frame in autumn, and protected from frosts during the winter months; but they may also be raised from seeds in the same way as the annuals and biennials, and cuttings of the young shoots may also be inserted in sandy soil under glass in spring. Most of the kinds however are so easily raised from seeds that it is the better means of propagation on the whole.

The genus *Godetia* is now included with *Genothera*.

CE. amcena (E. Lindleyi).—An annual 1-2 ft. high from N.W. America, with entire linear lance-shaped leaves. Flowers in summer, rose, with a crimson spot on each petal. The variety *rubicunda* from California has lilac-purple flowers with a deep blotch at the base of each petal. It is known as *Godetia rubicunda* also, and many fine varieties have been obtained from it, including a dwarf strain called *Tom Thumb*. The one called *Bijou*, having white flowers spotted with red at the base of the petals, grows about 9 in. high and is very free-flowering.

Culture &c. as above. Increased by seeds sown in spring or autumn.

CE. biennis (Common Evening Primrose).—A N. American biennial 2-4 ft. high, with a rosette of lower leaves, oblong-lance-shaped passing upwards into ovate-lance-shaped toothed and downy. Flowers in summer and autumn, beautiful primrose-yellow, about 3 in. across, fragrant, and at their best in the evening. The variety *Lamarckiana* (or *grandiflora*) has finer and larger flowers and is a fine border plant.

Culture &c. as above. This species once introduced to a garden is with difficulty eradicated, as it seeds freely and increases rapidly. Confined in masses to rougher parts of the garden, it is a plant difficult to surpass for its soft yet brilliant yellow colouring.

CE. bistorta.—A Californian annual with somewhat decumbent stems and lance-shaped leaves. Flowers in summer, yellow, with small deep blood-red spots at the base. Fruit 1½-2 in. long, twisting when ripe. *Veitchiana* is an improved form.

Culture &c. as above. Increased by seeds sown in autumn in cold frames and pricked out in spring; or by sowing in the

open border in April, or in gentle heat in March, afterwards transplanting the seedlings at the end of May to the open border.

Æ. californica.—A Californian perennial about 2 ft. high, with oblong-lance-shaped leaves. Flowers in summer, 1½–3 in. across, varying from white to pale pink, with a yellowish centre, very fragrant and opening in the evening.

Culture &c. as above.

Æ. crassicaulis.—A beautiful N. American biennial 1½–2 ft. high, forming tufts a yard through in the course of the season's growth. Leaves lance-shaped acute, unequally toothed and wavy, green with a white midrib. The flowers appear from July to October and are 3–4 in. across, pure white, tinted with yellow in the centre, and becoming faintly flushed with rose as they grow old.

Culture &c. as above. Increased by seeds sown in cold frames in autumn, and transplanting the seedlings in spring.

Æ. Drummondii.—An annual or biennial Evening Primrose, native of Texas. It grows 1½–2 ft. high, and has slightly downy trailing stems, and grey-green oval lance-shaped wavy leaves. The pale yellow blossoms appear from June to October and have obcordate petals. The variety *nana* is a dwarf free-flowering plant. There is a form of it called *alba*, the flowers of which however are pale creamy yellow and not white, as one would imagine from the name.

Culture &c. as above. Raised from seeds sown in autumn or spring.

***Æ. eximia* (*Æ. marginata*)**.—A handsome perennial 9–12 in. high, from the Rocky Mts. of Upper California. Leaves lance-shaped, downy. Flowers in July, white, 4 in. across, scented, with very long, slender calyx tubes. This species is also known as *Æ. caspitosa*.

Culture &c. as above.

Æ. fruticosa.—A perennial 2–3 ft. high, native of the United States. Leaves 1–2 in. long, ovate-lance-shaped, finely toothed. Flowers from June to September, golden-yellow, with broad, obcordate, erose petals. The varieties *major* and *Youngi* may possibly be a little better than the type; *ambigua* has rather pale yellow flowers, at first in corymbs, afterwards in racemes.

Culture &c. as above. This species may be increased from seeds, and also by dividing the tufts in spring or early autumn. It is also known as *Æ. serotina*.

Æ. glauca.—A beautiful N. American smooth and glaucous perennial 1–2 ft. high, with ovate repandly-toothed leaves. Flowers from June to October, pale yellow, large, with obcordate, erose petals. The variety *Fraseri* from S. Carolina is a dwarf form with brighter green oval lance-shaped leaves and deeper yellow flowers.

Culture &c. as above.

Æ. linearis.—A perennial 10–18 in. high, from the United States. Leaves linear or narrow lance-shaped, remotely toothed or entire. Flowers in summer, yellow, scarcely scented.

Culture &c. as above.

Æ. missouriensis.—A handsome N. American perennial with prostrate downy stems, entire, lance-shaped leaves, the edges and nerves of which are covered with white, silky down. Flowers from June to August, yellow, 4–5 in. across; petals broadly obcordate, calyx spotted with red. The variety *latifolia* or *macrocarpa* is a fine broad-leaved form.

Culture &c. as above. As this species often fails to ripen seeds it must be increased by dividing the tufts in mild weather in spring; or from cuttings of the young shoots inserted in sandy soil in gentle heat.

Æ. rosea.—A much-branched Mexican species about 1 ft. high, with oval lance-shaped toothed leaves, the lower ones of which are more or less lyrate. The flowers appear in May and June and continue up to October. They are among the smallest of the genus, and are usually more expanded in the evening and the early morning.

Culture &c. as above. Although really a perennial, this species may be raised from seeds sown annually in autumn or spring. It is not so striking as the other species, but may be used in sunny parts of the rockery.

Æ. speciosa.—A fine N. American perennial 2–3 ft. high, with lance-shaped, coarsely toothed leaves, downy beneath. Flowers from March to September, white, 3 in. or more across, becoming rosy with age. The drooping, cylindrical, pointed

buds will expand if the flower stems are placed in water.

Culture &c. as above. When this species fails to ripen seed, as it does occasionally in unfavourable seasons, it may be increased by dividing the tufts in early autumn or spring. Cuttings of the roots about 1½–2 in. long will also produce plants if placed in light sandy soil in a gentle hotbed in spring.

Æ. taraxacifolia.—A beautiful Chilean biennial 6 in. high, with somewhat trailing stems. Leaves downy, interruptedly pinnate, Dandelion-like. Flowers in summer, white, with a narrow tube 6 in. or more long, becoming red with age, and at their best in the evening. Fruit borne in the axils of the leaves, pear-shaped and 4-winged.

Culture &c. as above. Increased by seeds sown in autumn in cold frames, or in the open border in April, or in gentle heat in March. A good plant for warm sunny banks in the rock garden.

Æ. tenella.—A pretty Chilean annual 6–9 in. high, with rather glaucous linear spoon-shaped leaves and purple flowers produced in June.

Culture &c. as above.

Æ. tetraptera.—A downy Mexican annual 9–12 in. high, with leaves pinnately cut into toothed lobes. The very fragrant flowers appear in July and August. They are 3–4 in. across, white at first, afterwards becoming tinged with rose, and opening best at early morn and eve.

Culture &c. as above. The seeds of this species are best sown in the open border in April and May where the plants are to bloom, afterwards thinning the seedlings out about a foot apart.

Æ. triloba.—A North American annual 3–6 in. high, with ^{inter-venedly} pinnatifid toothed leaves, flowers from May to September, pale yellow, sweet-scented in the evening; petals obovate, 3-lobed.

Culture &c. as above.

Æ. vinosa (*Godetia vinosa*).—A Californian annual about 2 ft. high, with linear-oblong, smooth, slightly toothed leaves. Flowers in July and August, white tinted with purple.

Culture &c. as above.

Æ. Whitneyi (*Godetia grandiflora*). A pretty Californian annual 1–1½ ft. high, with oblong lance-shaped leaves. Flowers

in summer, 3–4 in. across, rosy-red, blotched with crimson, numerous, crowded. *Concolor* (white), *flammea* (crimson), and *flammea striata* (crimson striped), *Lady Albemarle* (brilliant rose), *Duke of York* (scarlet), *Bridesmaid* (rose and white), *Duchess of Albany* (white), *gloriosa* (deep blood-red), *Fairy Queen* (white and crimson), *Mandarin* (sulphur-yellow) are a few of many fine forms raised from this species. There is also a dwarf compact form with double deep crimson flowers.

Culture &c. as above. Increased by seeds.

EUCHARIDUM.—A genus with 2 or 3 species of Californian annuals, with alternate, ovate-lance-shaped or oblong entire leaves. Calyx tube linear, 4-angled, 4-parted, deciduous. Petals 4, clawed, 3-lobed or wedge-shaped obcordate, the middle lobe longer and much smaller than the other two. Stamens 4. Ovary 4-celled. Style filiform; stigma dilated, 2–4-lobed. Capsule linear-oblong, roundish.

Culture and Propagation.—These dwarf annuals about 9 in. high grow in ordinary soil, and to obtain the best results seeds should be sown in the open in early autumn to obtain flowers in early summer. Seeds may also be sown out of doors in March for autumn flowering.

E. Breweri.—An elegant annual, forming dwarf dense tufts. The short stems are furnished with oval or nearly linear-oblong entire leaves. The red or lilac-purple flowers are borne in great profusion and almost hide the foliage.

Culture &c. as above.

E. concinnum.—This species also makes dwarf compact tufts 9–12 in. high and has rosy flowers; the variety *album* being white or faint blush. *E. grandiflorum*, with deep rosy-purple flowers, is regarded as a variety of *concinnum*.

Culture &c. as above.

FUCHSIA (LADY'S EAR - DROPS).—This well-known genus contains about 50 species of smooth or hairy small shrubs or trees, with opposite, alternate and whorled, entire or toothed leaves. Flowers usually drooping, solitary on axillary stalks, or sometimes in racemes or panicles at the tops of the branches. Calyx coloured, tube produced beyond the ovary, limb 4-lobed. Petals 4, convolute,

or spreading, or reflexed. Stamens 8, with slender filaments, often protruding. Fruit a 4-celled pulpy berry.

Along the southern and western coasts the Fuchsia may be seen in all its beauty and vigour, and it is astonishing that such lovely flowering plants should not be more in favour in the flower garden. In less favoured localities than those referred to many kinds of Fuchsias will grow well, and although they may have their shrubby stems cut down during the winter like herbaceous plants, in spring new ones shoot forth with renewed vigour from the rootstock. It is probably owing to the numerous charming and tender varieties grown in green-houses that many people have obtained the impression that all Fuchsias require indoor treatment. Such, however, is not the case, and the kinds described below will be found to grow very well out of doors, and add a unique charm to the flower border. In severe winters the roots may be covered with a little coco-nut fibre or ashes, to guard them from the frost.

Culture and Propagation.—Fuchsias thrive in rich sandy loam and leaf soil, but grow well in ordinary garden mould. They are easily increased by cuttings of the young shoots inserted in sandy soil under glass in spring. They root very soon, and may be put singly into pots and grown on until large enough for planting out. By just pinching out the tip of the main shoots, new branches are caused to develop, and in a short time a strong bushy plant is obtained. Fuchsias cannot have too much light and air to make them sturdy in growth, and water should be given freely, except in winter, when they will go for weeks without a drop.

Seeds are ripened freely on many kinds, and may be sown in autumn after being cleansed from the pulp surrounding them; or in spring, in pots or pans, under glass. Unless new varieties are required it is not worth while to sow seeds, as cuttings are much quicker and better.

Besides the natural species, all the florists' varieties are useful for planting out in the summer time, and those with bronze or variegated foliage and dwarf habit make effective groups by themselves or in the front of a mixed border.

F. coccinea.—A pretty Chilean bush, with slender, downy branches, 3-6 ft. high. Leaves bluntly ovate, toothed, on

short hairy stalks, smoothish above, downy beneath. Flowers in summer; petals violet, obovate; sepals scarlet, purple at the base, oblong acute.

Culture &c. as above.

F. conica.—A vigorous Chilean species 3-6 ft. high, with scarlet sepals, and deep purple petals. Leaves 3-4 in a whorl, ovate flat, toothed, smooth; stalks downy.

Culture &c. as above.

F. corallina.—In the South and West of England this plant has produced thick stems to a height of 20 ft., and is useful for walls, or the sides of houses &c. Leaves opposite, or in whorls of 4 or 5, greenish-crimson above, dark crimson beneath; the young stems dark red. Flowers drooping; sepals crimson; petals dark plum-colour.

Culture &c. as above.

F. corymbiflora.—A Peruvian shrub 4-6 ft. high, with somewhat 4-angled branches, reddish and downy when young. Leaves large, opposite, oblong lance-shaped, almost entire, with a rosy midrib. Flowers in summer, scarlet, about 2 in. long, in drooping terminal clusters.

Culture &c. as above.

F. dependens.—A native of Chili, 2-4 ft. high. Leaves whorled, ovate-acute, toothed, slightly downy above, paler and more hairy beneath. Flowers in summer, in drooping leafy racemes, at the ends of the shoots; calyx soft scarlet; corolla deeper in colour.

Culture &c. as above.

F. globosa.—A fine Mexican shrub 5-6 ft. high. Leaves ovate-acute, small, toothed. Flowers from June to October, ^{drooping} globular, sepals purplish-red; petals ^{purple} fish-violet.

Culture &c. as above.

F. gracilis (*F. decussata*).—A graceful Mexican shrub 6-10 ft. high, with ^{scarcely} pubescent branches. Leaves opposite, on long stalks, smooth, distantly toothed. Flowers in summer and autumn, axillary, nodding; sepals scarlet, oblong acute; petals purple. There is a beautiful variegated form, with silvery foliage, not so hardy as the type. *Multiflora* is a free-flowering form, and *tenella* is a seedling.

Culture &c. as above.

F. macrostemma (*F. magellanica*).—A beautiful Chilean shrub 6-12 ft. high.

Leaves shortly stalked, 3 in a whorl, ovate acute, finely toothed. Flowers from July to October, axillary, nodding; calyx scarlet, with oblong-acute lobes, longer than the obovate, spreading petals. *F. conica*, *globosa*, *gracilis*, and *discolor* are probably only botanical varieties of this species, but from a garden point of view they are distinct enough.

Culture &c. as above.

F. Riccartoni.—This is one of the most graceful and hardy of Fuchsias. It is a garden hybrid from *F. globosa*, and was raised at Riccarton, near Edinburgh, about 1830. Its compact, twiggy branches are laden with bright red flowers during the summer and autumn. It stands severe winters well in many northern parts.

Culture &c. as above.

LOPEZIA.—A genus with about 6 species of smooth or downy branching erect herbs, with alternate leaves (or lower ones opposite), stalked and toothed. Flowers at the tips of the branches in racemes or corymbs. Calyx-tube with 4 linear lobes. Petals 4. Stamens 2, epigynous, one fertile, one sterile and petaloid. This is the chief peculiarity of the genus.

L. coronata.—An interesting Mexican annual 1½–2 ft. high, with ovate serrate leaves, and rose-purple flowers from July to September. *L. grandiflora* is a larger plant but not quite so hardy. It has orange-red flowers. The cut flower-spikes last a long time in water, and are thus valuable for bouquets &c.

Culture and Propagation.—Lopezias grow well in light soil and are increased by seeds sown in heat in March, and the seedlings planted out in May or the

beginning of June. They are not very effective if planted singly, but grown in masses in the border they make a very good display. They require abundance of water during the season.

GAURA.—This genus contains about 20 species of smooth, downy, or hairy annual or perennial herbs, rarely bushes, all natives of the Southern United States and Mexico. Leaves alternate, sessile or stalked, entire, toothed or sinuate. Flowers sessile or stalked in racemose spikes. Calyx tube more or less obconical, 3–4-angled, 3–4-lobed. Petals 3–4. Stamens 6–8, declinate; filaments slender, with a scale-like appendage at the base. Fruit indehiscent, 3–4-angled, leathery or woody.

Culture and Propagation.—Gauras grow best on a light well-drained soil in sunny positions. They are most readily increased from seeds sown in spring indoors or out, and transferred to flowering positions when large enough. They like plenty of water during the season and look well grown in bold masses.

G. Lindheimeri.—An elegant plant 3–4½ ft. high, with ovate-lance-shaped toothed leaves, often spotted with reddish-purple, and becoming linear lance-shaped upwards on the branching stems. Flowers from June to October, pure white and rose, in numerous long, slender spikes.

Culture &c. as above. Although really a perennial it is best to raise this species from seeds every year and treat it as an annual.

G. biennis, with white flowers changing to red, and **G. parviflora**, with yellow flowers, are other species not so well known.

XLIX. LOASEÆ

An order of erect or twining herbs, rarely shrubs, with forked branches, without tendrils and often clothed with stinging hairs. Leaves opposite or alternate, entire, lobed, pinnatifid, or pinnate; stipules none. Flowers regular, hermaphrodite, solitary, racemose, or cymose, or capitate; peduncles twisted opposite the leaves. Calyx tube adnate to the ovary, often with spirally inserted ribs, 4 or 5, imbricate or twisted, persistent. Petals 4–5, sometimes with petaloid scales alternating with the hooded petals; stamens usually numerous, often in clusters opposite the peduncles. Ovary usually inferior;

style filiform, entire, or 2-3-cleft. Capsule usually 1-celled with straight or twisted ribs.

MENTZELIA (including *BARTONIA*). A genus containing about 30 species of annual, biennial, or perennial plants with alternate leaves. Calyx tube 4-5-lobed. Petals 5, lanceolate or spatulate, rarely oblong or obovate. Scales none. Stamens numerous, free or in clusters.

Culture and Propagation.—*Mentzelias* and *Bartonia*s are showy plants when in bloom, and are worth a place in summer in the border. They grow easily in ordinary soil and may be raised from seeds sown in slight heat for planting out in May, or in the open in spring. The biennial species should be sown early in autumn in a cold frame, shifting the plants on into pots until spring, when they may be put outside. The annuals treated thus will bloom much earlier the following year. Some of the kinds however do not transplant very well, and are best raised from seeds sown in patches in the open border in April and May, and onwards until about the middle of June to secure a succession of blossom well into autumn.

M. albescens (*Bartonia albescens*).—A pretty Chilean annual or biennial 1-4 ft. high, with whitish shining stems and sinuately toothed leaves. Flowers in summer, pale yellow, with 10 petals.

Culture &c. as above.

M. bartonioides (*Eucnide* and *Microsperma bartonioides*).—An annual with flexuose and fleshy stems about 1 ft. long, native of the W. United States. Leaves ovate acute, lobed and serrated. Flowers sulphur-yellow, paler beneath, almost white, ovate or obovate, slightly serrated.

Culture &c. as above.

M. hispida.—A Mexican perennial 1½ ft. high, with almost sessile leaves. Flowers in summer, yellow, with obovate abruptly pointed petals.

Culture &c. as above.

M. lævicaulis.—A Californian biennial about 2 ft. high, with bright yellow flowers 2-3 in. across, opening in the morning and closing after midday. *M. nuda*, with white flowers, is very similar.

Culture &c. as above.

M. Lindleyi (*Bartonia aurea*).—A showy Californian annual 1-1½ ft. tall with oblong linear lanceolate

sessile leaves, 3-5 in. long. Flowers golden-yellow, Hypericum-like, with a zone of orange at the base, and numerous slender golden-knobbed stamens radiating from the centre.

Culture &c. as above. May be sown in the open border in patches.

M. oligosperma.—A perennial about 2 ft. high, native of Louisiana. Flowers in early summer, yellow, with pointed petals.

Culture &c. as above.

M. ornata (*Bartonia decapetala*).—A pretty annual about 2 ft. high, native of Missouri, with hairy glandular, deeply cut leaves. Flowers late in summer, 2½-4 in. across, white, scented, opening after sunset.

Culture &c. as above.

LOASA.—A genus with 50 species of erect, climbing or prostrate herbs with stiffish stinging hairs. Leaves alternate or opposite, entire, lobed, or very much divided. Calyx lobes 5, equal. Petals 5, hooded, spreading or erect, more or less united into a bell-shaped corolla, alternating with 5 scales, each having 2-3 bristles on the back, and 2 awl-shaped appendages at the base. Stamens numerous, in bundles opposite the petals; staminodes 10, 2 opposite each scale. Capsule smooth or ribbed, rarely twisted.

Culture and Propagation.—Only a few species are in cultivation, and these are easily raised from seeds sown either in gentle heat in February or March, or in the open border in May. The trailing kinds may be utilised for covering old tree stumps, arbours, trellises &c.

L. acanthifolia (*L. Placii*).—A pretty Chilean annual about 4 ft. high, with pinnately cut and toothed leaves, and yellow flowers in summer.

Culture &c. as above.

L. hispida.—A pretty trailing annual about 13 ft. high, native of Lima. Leaves oblong, deeply and pinnately cut, downy. Flowers in July, 1 in. across, bright lemon-yellow, with a green centre.

Culture &c. as above.

L. acutifolia (*L. aurantiaca*; *L. tricolor*).—A very pretty trailing Chilean annual or biennial with long-stalked and

pinnately lobed and crenate leaves 3-4 in. long. Flowers in August, coral-red, about 1½ in. across, with hooded or boat-shaped petals into the cavities of which the bundles of white stamens are depressed during the day, but toward evening spring up between the 5 pairs of yellow awl-shaped staminodes. Outside the latter are 3 purple-tipped scales.

Culture &c. as above. The stems attain a length of 10-12 ft. during the season. The whole plant—stems, leaves, and flowers—is covered with roughish stiff hairs mostly pointing downwards.

L. Pentlandi.—A beautiful Peruvian annual with leaves 4-6 in. long. Flowers in early summer, 2 in. across, with orange petals; stalks about 4 in. long.

Culture &c. as above.

L. prostrata.—A trailing flexuose Chilean annual with stalkless, heart-shaped, ovate, deeply angular leaves, and yellow flowers in summer.

Culture &c. as above.

L. vulcanica (*L. Wallisi*).—An annual about 2 ft. high, native of Ecuador. Leaves palmately 3-5-lobed and cut. Flowers in summer about 1½ in. across, white, with 5 erect scales or nectaries, red barred with yellow and white.

Culture &c. as above.

BLUMENBACHIA.—A genus with 12 species of erect or climbing herbs with stiffish, stinging hairs, and opposite, almost sessile or stalked, entire, lobed, or pinnatifid leaves. Floral characters almost the same as in *Loasa*. The capsule when ripe splits to the base into 10 valves.

Culture and Propagation.—This is practically the same as for the *Loasas*. The plants flourish in ordinary good garden soil in open sunny situations, and may be used in the flower border in masses. The seeds may be sown in the open border where the plants are to bloom, and the seedlings afterwards thinned out.

B. chuquitensis.—A Peruvian climber with oblong lance-shaped pinnate and deeply cut leaves. Flowers in September, consisting of 5-10 boat-shaped petals, yellow inside, red outside.

Culture &c. as above. Sticks should be placed to the plants for climbing.

B. coronata (*Caiophora coronata*).—A graceful, tufted, erect biennial about 1½ ft. high, native of Chili. Leaves narrow, twice pinnately cut into small segments. Flowers in summer, 2 in. across, pure glossy white, with 5 hooded hairy petals, dotted inside.

Culture &c. as above.

B. insignis (*Loasa palmata*).—A Chilean trailer about 1 ft. high, with lower leaves 5-7-lobed; upper ones deeply twice pinnatifid. Flowers in summer, about 1 in. across, white with reddish scales.

Culture &c. as above.

GRAMMATOCARPUS.—This genus contains only the following species, which is also known as *Scyphanthus elegans*:—

G. volubilis.—A Chilean annual with opposite or twice or thrice pinnately cut downy leaves. Flowers in summer, axillary, sessile, yellow, calyx-tube linear, elongate, 5-lobed. Petals 5, saccate, alternating with smaller bristly scales. Stamens numerous in bundles opposite the petals. Staminodes 10, papillose, in pairs opposite the scales.

Culture and Propagation.—This is practically the same as for the *Loasas* above. Seeds may be sown in cold frames in autumn and the seedlings wintered under glass until the end of the following May. Or they may be sown in gentle heat in February and March, for planting out at the same period. The plants flourish in ordinary good and well-drained garden soil, and as they climb 6-9 ft. high may be used for covering trellises, arbours &c.

L. PASSIFLOREÆ—Passion Flower Order

This order contains mostly plants of climbing habit, with alternate lobed leaves and lateral tendrils. They are remarkable for having a corona of beautifully coloured radiating filaments between the petals and stamens. Flowers regular, hermaphrodite or 1-sexed. Calyx tube persistent; lobes 3 or more, leathery. Petals none or as many as the calyx-lobes. Stamens 3-5,

rarely more, perigynous and inserted with the petals in the throat of the calyx, or hypogynous. Ovary superior, 1-celled. Style simple, or 3-5, with club-shaped or dilated stigmas. Fruit capsular or a berry, often edible.

The order has about 20 genera with 250 species, but the only hardy representative is described below.

PASSIFLORA (PASSION FLOWER).—

The characters of this genus are the same as those of the order above described. The popular name is derived from the parts of the flower being supposed to resemble respectively the crown of thorns (the corona), the five wounds (the 5 stamens), and the nails (3 stigmas) of our Lord's Passion.

P. cærulea.—A beautiful climber from Brazil and Peru, with smooth, 5-parted leaves and oblong entire lobes. Flowers from June to October, faintly scented, scarcely lasting more than a day. Calyx segments pale greenish-white; petals similar in shape, varying from white to pale blue and rosy-red; styles purplish; filaments of the corona in two circles, purple at the base,

white in the middle, blue at the tips. Fruit egg-shaped, yellow and fragrant when ripe. The variety *Constance Elliott* is a beautiful white-flowered form, quite as hardy as the type.

Culture and Propagation.—The Passion Flower is best grown against a warm south wall, although in south coast localities it may be trained over arbours and trellises. It likes a rich turfy loam mixed with a little peat and sand. In spring cuttings of the young shoots about 6 in. long may be inserted in sandy soil under a glass. As soon as well rooted they may be potted off singly and grown on for some time in a greenhouse, gradually giving more light and air to harden the plants off for placing out of doors.

LI. CUCURBITACEÆ—Gourd Order

The characteristics of this order are rendered more or less familiar by the Cucumber, Marrow, Melon, and Gourd. They are mostly climbing or prostrate annual herbs, often with a large fleshy perennial rootstock. The leaves are alternate, simple, lobed or divided. The tendrils, when present, are lateral, solitary, simple or branched, and spirally twisted. Flowers monœcious or diœcious, white or yellow, rarely red or blue. Calyx-tube adnate to the ovary; lobes 5, rarely 3 or 6. Petals 5, rarely 3 or 6, free, or rarely gamopetalous, often confluent with the calyx. Stamens usually 3 (rarely 5, or 1, 2, or 4). Fruit inferior, usually fleshy, often large, variable in form and sometimes highly coloured.

This order is interesting chiefly on account of the many beautiful, diversely shaped, and brilliantly coloured fruits—popularly known as Gourds—which it yields, chiefly from *Cucurbita Pepo*, a native of the Levant. Gourds vary from $\frac{1}{2}$ oz. to 200 lbs. in weight, and are round, flask-shaped, ringed, warted, striped, mottled, angled, snake-like &c., with many intermediate and indescribable forms—all so highly curious and interesting that they are well worth a place in the ornamental garden, trained up gnarled tree trunks, over trellises, or arbours, hanging from hedges &c., the better to show their fruits.

Culture and Propagation.—Gourds thrive in well-dug and well-manured soil. Seeds are best sown in a cool frame at the end of April. After germination as much light and air as possible should be given to make the plants sturdy, but care must be taken, especially at nights, to protect them

from the spring frosts. By the end of May or the first week of June, the seedlings may be transferred to the positions in which they are to flower and fruit. They require plenty of water during the summer, and should be well mulched with rotted manure to prevent evaporation from the soil and to replenish the food taken from it by the gross-feeding roots.

Gourds have been grown successfully simply by sowing the seeds in the flowering quarters about the second week in May, and in mild localities this method might be adopted to save the labour of transplanting from frames.

THLADIANTHA.—This genus consists of 3 or 4 species of softly downy climbing plants with ovate heart-shaped, deeply lobed, toothed leaves, diœcious flowers, and oblong, fleshy, many-ribbed fruits, with hollows between the ribs.

T. dubia, the only species generally grown, is a native of India and China. It has tuberous roots and climbing stems which reach a height of 12 to 20 ft. in the course of the season in favourable situations. They are furnished with ornamental heart-shaped, hairy leaves, and in summer produce an abundance of yellow flowers, succeeded by bright red fruits about the size and shape of a hen's egg and covered with downy hairs.

Culture and Propagation.—This species grows in ordinary soil, and is best against a sunny wall, although almost any position will suit it in milder parts.

It is rarely seen in fruit, simply because the fact mentioned above is usually overlooked, viz. that the flowers are diœcious, that is, the male and female flowers are borne on separate plants. To secure a crop of the bright red fruits, therefore, it is essential to have a male and female plant close together, or at least convenient to one another, so that the pollen may be used for fertilising the pistils. The climbing stems die down to the tuberous rootstock every winter.

Propagation is easily effected by dividing the tuberous rootstocks in spring. Seeds may also be sown in gentle heat about March, afterwards pricking out the seedlings and growing the plants on in pots until about the end of May or beginning of June when they may be transferred to the outdoor garden.

BRYONIA (BRYONY).—A genus of slender climbing perennial herbs, with 3-5 angled or lobed leaves, and small dirty white or yellow flowers usually diœcious. Fruit small, red, black, or green.

The plant known as 'Black' Bryony (*Tamus communis*) is described at p. 884.

B. dioica.—A hairy slender climber, native of the hedges and thickets in England. It has large, fleshy, tuberous rootstocks, and roundish heart-shaped 5-lobed leaves 3-5 in. across. The hairy greenish flowers $\frac{1}{2}$ – $\frac{3}{4}$ in. across appear in corymbose clusters from May to September, and the female ones are followed by red berries $\frac{1}{4}$ in. in diameter.

Culture and Propagation.—This grows rapidly in any soil, and is very useful for trailing over old hedges, fences, walls &c. Notwithstanding the fact that it is a British weed it is a very ornamental plant both when in flower and in fruit. It may be increased by sowing seeds in the open ground when ripe. Once established in a garden to clamber over rough hedges, fences &c. it may be left to look after itself.

B. erythrocarpa (Bryonopsis).—An East Indian annual climber often attaining a height of 9-10 ft. in the course of the season. It has alternate palmate leaves with 5 oval lance-shaped toothed lobes separated from each other by roundish sinuses. Both male and female flowers are borne on the same plant, and not on separate ones as in the Bryony. They are yellowish-green, the female (or pistillate) ones being in due course succeeded by roundish berries, about the size of a Cherry, which are green at first, then striped with white and afterwards deep crimson spotted with white.

B. laciniosa is closely related but differs chiefly in the berries, which are yellowish-green striped with white, and not so ornamental as those of *B. erythrocarpa*.

Culture and Propagation.—Owing to the graceful climbing habit and foliage and the colouring of the fruits, these plants are worth growing among other annual climbers and are useful for covering trellises &c. Seeds may be sown in gentle heat in March, and the young seedlings grown on in pots until the end of May and then planted out.

ABOBRA.—A genus with 2 or 3 species of smooth or rough climbers, with cut leaves, and usually 2-cleft tendrils. Flowers diœcious, slender, greenish. Berry small, drooping.

A. viridiflora.—A native of S. America, with dark green elegantly cut and divided glossy pale green leaves, fragrant flowers, and oval scarlet fruits about the size of a Filbert borne by the female flowers.

Culture and Propagation.—This plant grows rapidly, and when trained over arbours, trellises &c. looks very handsome, especially when in fruit. It has fleshy tuberous roots, which may be taken up in autumn, and stored like Dahlias in a cool, dry place free from frost. To secure a good supply of the

scarlet fruits male and female plants should be grown together.

This species may be increased by dividing the tuberous rootstocks, and where the male and female kinds have been noted it is easy to place roots of each together at planting time in spring. Seeds may also be sown in gentle heat in spring. The seedlings must be pricked out in due course and grown on in pots under glass until about the end of May or beginning of June, when it will be safe to transfer them to the open ground. Cuttings of the young shoots from the tuberous roots may be rooted in sandy soil in a hotbed in spring in the same way as recommended for Dahlias (see p. 519).

LII. BEGONIACEÆ—Begonia Order

This order consists of *Begonia*, *Begoniella* and *Hillebrandia*. The last genus was in cultivation several years ago, but has since become a lost garden plant; and *Begoniella* has not yet been introduced. For practical gardening purposes, the order is thus represented only by the genus *Begonia*.

BEGONIA (ELEPHANT'S EAR).—A genus containing upwards of 350 species of juicy herbs or undershrubs, many having perennial tuberous rootstocks. Leaves alternate, simple, more or less unequal sided, entire, lobed or parted, irregularly toothed. Flowers often showy, monœcious. Male flowers consisting of 2 large outer (sepaloid), and 2 small inner (petaloid), segments. Stamens numerous, free or united in one bundle. Perianth of the female flowers has 2-10 segments, of which the 2 outer ones are larger and sepaloid. Ovary inferior, often 3-, rarely 2-, or 4-5-celled. Styles 2-4, free, or united at the base, with branched twisted stigmas. Fruit a capsule, usually 3-angled and unequally 3-winged. Seeds numerous, minute.

Begonias, both double and single, are now so well known in the flower garden that one can scarcely credit the fact that less than a generation ago they were not only unknown but not dreamt of. The forms that now rival the Rose, Carnation, Hollyhock, and Camellia in form and colour have all been developed by careful cross-breeding within the last quarter of a century, and they have in that short time reached such a stage that the characters of their progenitors have been

entirely lost. Indeed, some of the original parents themselves have disappeared altogether from cultivation.

The species chiefly concerned in the development of the florist's Begonia were *B. Pearcei* (yellow), *B. boliviensis* (bright scarlet), *B. Veitchi* (bright orange-red), *B. Clarkei* (rosy-red), *B. rosæflora* (rosy-red) and *B. Davisi* (bright crimson)—natives of Peru and Bolivia. some of them at an altitude of as much as 11,000 to 13,000 ft. It will be noticed that with the exception of *B. Pearcei* they have all red flowers, and yet their progeny have crimson, pink, scarlet, rose, white, yellow, orange and innumerable intermediate shades. *B. Pearcei*, *B. boliviensis*, and *B. Veitchi* have been more used than the other three species, and they are most in evidence in the beautiful hybrids of to-day. All the flowers with yellow shades show the influence of the yellow-flowered *B. Pearcei*.

The value of the florist's Begonia as a garden plant is now well recognised, and owing to the great beauty of the flowers and the length of time they last, there is a probability that many of the older plants used for bedding out in summer will have to make way more and more for the Begonia every year.

Although both single and double kinds may be used, the singles are on the whole better for bedding out. To make a good display tubers at least one year old should be used. After the winter's rest in sand or coco-nut fibre in a dry, cool place free from frost, the tubers about February, March, or April may be placed in gentle heat to start them into growth. They should be gradually hardened off by putting in a light, airy place, and by the beginning of June they will be sturdy enough for planting out. In the autumn, when the leaves and stalks are withering, the plants should be lifted and dried carefully, removing all decaying stems and leaves from the tubers. These may then be stored in sand or fibre as above stated.

The soil for Begonias should have been well dug and manured some time previous to planting out, and should consist of sandy loam and leaf soil. After planting the surface may be top-dressed with coco-nut fibre; some of the dwarf-tufted *Violas* (see p. 234) with flowers that will harmonise may be used as a carpet in between.

Propagation.—Bedding Begonias may be increased by seeds, cuttings, or division of the tubers. Seeds, which are very fine and require some skill in sowing thinly, are perhaps the best and quickest means of increasing the plants, but there is of course always likely to be great variation in the colour of the flowers. The *modus operandi* is as follows:—About the end of January shallow pans or boxes of sandy loam and leaf soil are

prepared, being well mixed together, with some finely sifted soil on top to make the surface level. The whole is firmly pressed and watered with a very fine-rosed can, or dipped. The dust-like seeds should be sown carefully and as evenly as possible over the surface, but not covered with any soil. The pans or boxes are then placed in a temperature of 65°–70° F. with bottom heat. As soon as the seedlings become large enough they are pricked out into similar pans or boxes, and this operation may have to be again performed if the seedlings become too crowded before planting out time arrives. Increase by leaf-cuttings is only practised when some special varieties are required to be kept pure. In dividing the tubers care must be taken not to cut through a bud at the apex.

Of late years the forms of a shrubby species—*B. semperflorens*—have become popular as bedding plants. They are valuable chiefly on account of their rather small foliage, which towards autumn assumes many beautiful tints of colour. *Vernon's* variety becomes deep purple-crimson. The flowers of this section are small, white or pink, and mostly single. They produce seeds freely and may be increased as directed above.

In the case of tuberous Begonias it is scarcely necessary to occupy space with a list of varieties. The names given are so purely fanciful and unstable that each year sees quite a new selection. It is therefore best to consult a nurseryman's current catalogue if it is desired to secure the most recent novelties.

LIII. CACTEÆ—Cactus Order

A curiously interesting order of plants abounding in watery or milky juice, and mostly devoid of leaves, the functions of which are performed by the stems, the latter varying a good deal in shape, being cylindrical, conical, flattened, angular, ribbed &c., and often covered with hooked spines, or cushions of prickles. Flowers regular and hermaphrodite, often large and brilliant, with numerous coloured sepals and petals and thread-like stamens; style long, often with a many-cleft, radiating stigma. Fruit a berry, inferior; seeds numerous. All natives of America, chiefly Mexico, but several from Peru and Brazil.

Being natives of dry sandy regions Cactaceous plants require similar conditions under cultivation. They grow well in a mixture of sandy soil with old mortar &c. added. Only a few kinds are grown and are seen chiefly in cottagers' windows. The 'Whip Cactus' (*Cereus flagelliformis*), with prostrate,

creeping, 10-angled stems and red or pink flowers, is fairly common. Many of the *Mamillarias* and *Echinocactus* and *Cereus* could be grown in rooms, as they take up little space and require practically no attention. Their cultivation out of doors is hardly worth attempting except in the most southern parts of the country, but it is questionable if they will ever receive much attention except from enthusiasts, and even these usually grow cool in their cultivation after a year or two.

LIV. FICOIDEÆ—Fig Marigold Order

An order containing about 450 species of small shrubs or herbs, mostly uninteresting, with opposite or alternate, usually fleshy or thickened, flat, round, or triangular leaves. Flowers usually hermaphrodite, regular. The genus *Mesembryanthemum* is the only one of any garden value.

MESEMBRYANTHEMUM (FIG MARIGOLD).—A genus including about 300 species of erect or prostrate herbs with fleshy opposite leaves, very variable in form, and conspicuous white, yellow, or rosy Daisy-like flowers. Calyx tube adnate to the ovary, limb 5-8-lobed. Petals numerous, linear, in one or more series. Stamens numerous. Capsule contained in the fleshy calyx tube.

Culture and Propagation.—Although not hardy, several species are grown out of doors in summer. They are easily grown in a mixture of lime-rubble, loam, sand, and rotted manure, and require the sunniest possible place to develop their flowers properly. They may be easily increased by putting portions on moist sand in the sun, and will root in a few weeks. They are nearly all natives of S. Africa.

M. cordifolium variegatum.—This handsome little perennial is probably the best known member of the genus and is largely used for edgings &c. The small, flat, heart-shaped leaves are distinctly edged with creamy white, and when covered with bright rosy-purple flowers the effect is elegant.

Culture &c. as above. Easily increased by cuttings inserted in sandy soil under glass about March and April.

M. crystallinum (*Ice Plant*).—A hardy procumbent S. European annual, covered with large glittering crystal-like granules,

which give the plant a frosted appearance. Leaves alternate, ovate, wavy. Flowers from May to August, white, axillary, nearly sessile.

Culture and Propagation.—This species grows well in any good soil and may be used in the rockery in sunny positions. Seeds should be sown in gentle heat in March. The seedlings should be pricked off, and by June they will be large enough to plant out 6-8 in. apart.

M. pomeridianum.—A South African annual 3-6 in. high, with cylindrical downy reddish stems, and thick oblong lance-shaped leaves, ciliated on the margins. The golden-yellow flowers about 2 in. across, and somewhat resembling the yellow-flowered Sweet Sultan, appear in August, and are remarkable for not expanding fully until towards the evening.

Culture &c. as above and for *M. tricolor*.

M. tricolor.—A pretty tufted annual with long, linear acute leaves. Flowers pink and crimson with a dark eye, on long stalks covered with small granular protuberances. There is also a pretty white-flowered variety called *album*.

Culture and Propagation.—As this plant dislikes being transplanted it is best to sow the seeds in the open about April where the plants are to bloom. They make pretty edgings to borders, and during the sunniest part of the day they are a mass of blossom.

LIV. UMBELLIFERÆ—Sea Holly Order

A large order containing over 150 genera and 1,300 species of herbs or shrubs, rarely trees, with usually much-divided leaves. Flowers more or

less regular, hermaphrodite, or often polygamous-monœcious, rarely diœcious, in compound or simple umbels, or rarely capitate or whorled. Calyx 5-lobed, or almost absent. Petals 5, epigynous, usually obovate or obcordate, the tips usually incurved. Stamens 5, filaments incurved. Ovary inferior, usually 2-celled; styles 2, distinct, erect or recurved. Fruit of 2 indehiscent, 1-seeded, flattened carpels or mericarps, with 10 more or less prominent ridges or oil canals technically known as vittæ.

TRACHYMENE. — A genus with about 14 species of usually hairy herbs, having ternately dissected, or rarely divided, toothed leaves, and flowers in simple umbels.

T. cærulea (*Didiscus cæruleus*).—A native of W. Australia 1-2 ft. high, with leaves once or twice three-parted; lobes linear wedge-shaped, trifid or incised. Flowers in July and August, lavender-blue, on long stalks, each bearing an umbel 1-2 in. across. There is also a white-flowered variety rarely seen.

Culture and Propagation. — This annual is best raised from seeds sown in heat in February or March, but care must be taken not to keep the seedlings too moist, or they may damp off. By the end of May they will be strong enough for planting out in rather good warm soil. It may be noted that plants with blue flowers are very rare in the Umbellifer order, and this rather tender annual is therefore decidedly interesting.

ERYNGIUM (ERYNGO; SEA HOLLY). A genus containing over 100 species of usually spiny, perennial, Thistle-like herbs, with spiny-toothed, lobed or dissected leaves, rarely entire and stiffly ciliated. Flowers sessile, in dense heads or spikes, surrounded by a whorl of spiny bracts. Calyx teeth rigid, acute or pungent. Petals erect. Disc dilated. Fruit ovoid or obovoid, scarcely compressed, with a broad commissure.

Culture and Propagation.—Many of the Eryngiums are now very popular garden plants, and are more valued for the appearance of the bracts than for the flowers themselves. Some of the more highly coloured species like *E. amethystinum* when grown in masses or beds by themselves are very effective. They thrive in a light, well-drained, sandy loam, and may be increased by very careful division early in autumn or in spring. If not carefully done the divided plants may, and often do, die. They are perhaps better raised from seeds sown as

soon as ripe, and kept in a cold frame until spring, when they will germinate. By September the seedlings will be fit for planting out, or if the season be unfavourable, they may be planted the following spring. The chief point to remember in the cultivation of Sea Hollies is the fact that they dislike moist or wet situations, and enjoy warm and thoroughly well-drained soil.

The following are a few of the best for garden purposes, although many others are to be found in botanical collections:—

E. alpinum.—A native of the Alpine pastures of Switzerland, 1½-2 ft. high. Lower leaves long-stalked, heart-shaped, toothed, undivided, the upper ones stem-clasping, palmately lobed, and serrately fringed. Flowers in summer, blue or white, in oblong heads; bracts 10-20, of a beautiful deep blue, the outer ones pinnatifid, the inner ones deeply serrate-ciliate. The erroneous name of *cælestinum* has recently been applied to this plant by some growers and may lead to confusion.

Culture &c. as above. This species likes a rather chalky well-drained soil. Increased by seeds or division.

E. amethystinum. — A beautiful but rather straggling species 1-1½ ft. high, native of Dalmatia and Croatia. Lower leaves pinnatifid, with cut spiny lobes. Flowers in July and August, amethyst-purple, in rounded heads, with 7-8 long lanceolate toothed bracts and brilliant violet-purple stems.

Culture &c. as above. This species is often confused with *E. oliverianum*, a much taller and more vigorous plant. It is easily raised from seed.

E. Bourgati.—This is the 'Chardons bleus' of the Pyrenees, and grows 1-2 ft. high. Lower leaves roundish, 3-parted, with pinnatifid or forked lobes. Flowers from June to August, bluish, in ovoid heads, with 10-12 beautiful long, lance-shaped, prickly bracts of a striking bluish sea-green colour.

Culture &c. as above.

E. bromeliæfolium.—A distinct Mexican plant 3–4 ft. high, with broadly lance-shaped linear, parallel-veined leaves, having awl-shaped teeth along the margins and reminding one of some of the tropical Bromeliads. Flowers in July, white, in round heads, with 10 lance-shaped acute bracts.

Culture &c. as above.

E. cæruleum.—A pretty Himalayan perennial 2–3 ft. high, with oblong, entire or slightly crenate lower leaves, borne on long stalks, the upper ones on the stems being stalkless and palmately divided. The steel-blue flowers appear in summer in heads surrounded by steel-blue spiny bracts.

Culture &c. as above. Increased by seeds or division. Quite hardy in most places in well-drained soil.

E. corniculatum.—This closely resembles *E. alpinum* in appearance and might easily be mistaken for it if the two species were not seen side by side. It grows about 2 ft. high, and has smaller and more loosely arranged steely-blue flower heads and bracts.

Culture &c. as above.

E. eburneum.—This species is a native of Monte Video, and is closely related to *E. bromeliæfolium*. It grows 4–6 ft. high and has stiffer and stronger stems. The leaves are also broader and stiffer, and are slightly recurving. It produces its heads of whitish flowers tinged with yellow in July and August, and is on the whole a very ornamental plant for massing in groups for subtropical effect.

Culture &c. as above.

E. giganteum.—A native of the Caucasus 3–4 ft. high, with forked stems. Leaves heart-shaped, lower ones entire, roughish, downy or smooth beneath, net-veined, crenate-toothed; upper ones stem-clasping, deeply lobed, spiny. Flowers in summer, blue, in ovoid heads, surrounded by 8–9 ovate or lance-shaped, deeply cut, spiny bracts of a more or less beautiful blue-green tint.

Culture &c. as above. This species flourishes in almost any position so long as the soil is well drained.

E. maritimum (*Common Sea Holly*). A native of the sandy shores of the British Islands, with stout stems 1–2 ft. high. Leaves of a whitish glaucous hue, lower ones roundish, 3-lobed, spiny, upper ones

palmate. Flowers from July to October, bluish-white, in ovoid heads, with 5–7 ovate, spiny-serrate bracts.

Culture &c. as above.

E. oliverianum.—This species is often confused with *E. amethystinum*. It grows much taller than that species, from 2–4 ft. In habit and general appearance it resembles *E. alpinum*, and produces in great abundance its heads of bright steely-blue flowers, with 10–12 bracts, during the summer.

Culture &c. as above. Easily raised from seeds.

E. pandanifolium.—A noble species from Monte Video, 10–15 ft. high. Lower leaves 4–6 ft. long, very glaucous, concave, pointed, with spiny margins. Flowers purplish, in rather small roundish heads with scarcely any bracts.

Culture &c. as above. This fine species is perhaps not quite so hardy as some of the others, but it grows very well in southern parts. As a single specimen on a lawn it looks well. *E. Lasseauxi* is nearly related, and quite hardy. It grows only 6–7 ft. high, however, and its narrow leaves rarely exceed a yard in length.

E. planum.—A native of E. Europe, 1–2 ft. high, with white and blue stems. Lower leaves ovate heart-shaped, crenate, undivided, on long stalks; upper ones stalkless, more or less 5-parted and serrate. Flowers in summer, blue, in rounded heads, with 6–8 lance-shaped, remotely spiny-toothed bracts.

Culture &c. as above.

ASTRANTIA (MASTERWORT).—A genus of smooth, erect, often branched, herbaceous perennials, with palmately lobed and dissected toothed leaves. Umbels simple or irregularly compound, surrounded by an involucre of many radiating, often coloured bracts. Flowers polygamous, the fertile ones on shorter stalks than the sterile. Calyx teeth very sharp. Petals notched with a long inflexed point. Fruit ovoid or oblong, almost round; commissure broad; carpophore none.

Culture and Propagation.—Astrantias although not particularly showy have a peculiar beauty of their own. They grow in any ordinary soil, but prefer a rather damp position, and are useful for banks, borders, or woodland walks. They may be increased by division in early autumn or spring. Seeds may also be sown in

cold frames as soon as ripe, and the seedlings may be transplanted in mild weather the following spring.

A. carniolica.—A pretty species, 6–12 in. high, native of Carniola. Lower leaves with 5–7 oblong-pointed, unequally serrated lobes. Flowers in May, white. Bracts 12–13, entire, white, with a central green line tinged with red.

Culture &c. as above.

A. helleborifolia (*A. maxima*).—A native of the E. Caucasus, 1–2 ft. high. Lower leaves with 3 ovate-lance-shaped, unequally serrated lobes. Flowers in June, pink, with 12–13 ovate-lance-shaped, bristly bracts of the same colour, somewhat exceeding the umbel.

Culture &c. as above.

A. major.—A very distinct and pretty European species 1–2 ft. high, now naturalised in woods near Ludlow and Malvern. Leaves with 3–7 ovate-lance-shaped, rather 3-cleft, bristly serrated lobes. Flowers in June and July, white or pink, with 15–20 linear lance-shaped, entire reticulated bracts, white beneath, dark green tinged with pink above.

Culture &c. as above.

A. minor.—An interesting little perennial 6–9 in. high, native of the Alps and Pyrenees. It has leaves palmately cut or divided into 7–9 lance-shaped acute toothed lobes. The small rosy-white flowers appear in June and July, the heads being surrounded by 12–15 whitish bracts.

Culture &c. as above.

HACQUETIA.—A genus containing only the species described below:—

H. Epipactis (*Dondia Epipactis*).—A curiously pretty perennial 3–6 in. high, native of Carinthia and Carniola. Lower leaves stalked, palmate, with 3 wedge-shaped, 2–3-cleft leaflets. Flowers in spring, greenish-yellow, polygamous, on short pedicels, with an involucre of 5–6 obovate bracts, longer than the umbels. Calyx teeth very sharp. Petals notched.

Culture and Propagation.—Being rather slow in growth it is safer not to divide the plant until strong healthy clumps have been formed. Spring is the best time for division. The plant likes a good rich loam, and may be used in the rockery, edges of borders, banks &c.

MOLOPOSPERMUM.—A genus containing only one species here described:—

M. cicutarium.—A very ornamental perennial 3–6 ft. high, native of the mountains of Central Europe. The strong hollow and furrowed stems are furnished with large handsome leaves pinnately divided and cut into irregularly toothed lance-shaped segments. The yellowish-white polygamous flowers are borne in May in many-rayed umbels, and have oblong or wedge-shaped petals with incurved or slightly reflexed tips.

Culture and Propagation.—This plant makes an elegant bush of dense irregular growth, with finely divided Fern-like foliage that renders it suitable either for grouping on grass or for the wilder and more picturesque parts of the garden. It flourishes in ordinary good garden soil with plenty of moisture in summer, and may be increased by division of the roots in early autumn or spring; or by seeds sown in cold frames when ripe, afterwards transferring the seedlings in mild weather in spring.

BUPLEURUM (HARE'S EAR).—A genus containing 60 species of quite smooth shrubs or rigid annual or perennial herbs, with mostly entire leaves. Flowers usually in compound many-rayed umbels. Calyx teeth obsolete. Petals flat, incurved at the apex. Fruits flattened.

B. fruticosum.—A Spanish shrubby species 3–6 ft. high, with purplish branches and oblong, leathery, sea-green stalkless leaves narrowed at the base. Flowers in July, yellowish, with long involucre bracts.

Culture and Propagation.—This species grows readily in ordinary soil, and may be increased from seeds sown as soon as ripe in cold frames, or in spring, afterwards pricking the seedlings out when large enough for transferring to the open border. Or the plants may be more readily increased by dividing the roots in early autumn or spring.

There are other species such as *fruticescens*, *graminifolium*, *falcatum*, *rotundifolium* &c., but they are not generally grown except in botanic gardens.

MYRRHIS (MYRRH; SWEET CICELY).
A genus with 2 species of hairy perennials, with finely cut, pinnate leaves and white polygamous flowers. Calyx teeth

minute or absent. Petals wedge-shaped, obovate or oblong, incurved at the tip. Fruit flattened, shortly beaked. Carpophore 2-cleft.

M. odorata.—A graceful native plant 2-3 ft. high, with ternately decomposed leaves, having pinnately cut leaflets. Flowers in May, white, sweet-scented, with involucre of many lance-shaped ciliated bracts. Fruit about 1 in. long, with 5 prominent ribs, usually clothed with minute rigid hairs.

Culture and Propagation.—This species is suitable for naturalising near woodland walks, shrubberies, and wild places generally. It may be increased by division in early autumn or spring or by seeds sown out of doors as soon as ripe in prepared spots, afterwards pricking the seedlings out in spring. It was once used as a pot herb in this country.

FENICULUM (FENNEL).—A genus of 3 or 4 species of tall, smooth, biennial or perennial herbs, with finely divided, pinnate leaves, and yellow flowers in compound umbels.

F. dulce and **F. vulgare** (or *officinale*) are best known. The former, although a biennial, is considered by some to be merely a form of the perennial *F. vulgare*, a native of Britain and S. Europe.

Culture and Propagation.—Although useful as pot herbs, the Fennels have such graceful feathery foliage that they are worth a place on any waste bank. They will thrive in ordinary soil, and may be easily increased by seeds sown in spring out of doors or by division of the roots early in autumn.

MEUM.—A genus with only one species:—

M. athamanticum (*Spiguel*).—An elegant and fragrant native perennial 6-18 in. high, chiefly found in northern alpine pastures. The oblong leaves are pinnately divided and cut into numerous Fern-like leaflets, and the white or purplish flowers are borne in compound umbels in June and July.

Culture and Propagation.—This graceful perennial is chiefly valuable for its finely divided elegant foliage, and is a suitable plant for the border or rock-garden. It flourishes in ordinary garden soil, but likes plenty of water during the summer months to keep it in a fresh-looking condition. It may be increased by dividing the roots in early autumn or

spring; and by seeds sown in the open border or cold frames when ripe.

ACIPHYLLA.—A genus containing about 20 species of curious perennial herbs with pinnately divided and much-cut leaves. Flowers white, often polygamous-dioecious, borne in compound umbels. Calyx teeth usually conspicuous. Petals acute or tapering, concave or slightly inflexed at the tip.

A. Colensoi.—This is a native of New Zealand and forms a roundish spiny bush 4-8 ft. high in its native country. *A. Lyallii* is very similar in habit but is smoother in all its parts, the leaves being pinnately divided into sharp spiny segments. *A. squarrosa*, known as the 'Bayonet Plant,' is the best known species and is similar to the others in habit and appearance.

Culture and Propagation.—These plants flourish in well-drained sandy soil and are suitable for warm sunny parts of the rock garden. They may be increased by dividing the roots in early autumn or spring, or by sowing the seeds in cold frames when ripe.

FERULA (GIANT FENNEL).—A genus with 60 species of glaucous smooth herbs, with large, finely divided leaves, and tall branched flower stems. Umbels compound, many-rayed. Fruit almost flat winged at the sides.

Culture and Propagation.—The Giant Fennels are noble-looking plants, especially if grown in deep rich soil. They are easily grown, and should be planted in positions in which they are not likely to be disturbed for a few years. Either singly or in small groups near a shrubbery, or on a lawn or grass land, they have a graceful effect, especially in early spring when their deep green beautiful foliage is seen to great advantage.

The plants have thick roots, and should be very carefully divided when an increase is desired. They are easily raised from seed, which should be sown as soon as ripe in a prepared spot, and afterwards carefully transplanted the following spring in mild showery weather.

The following are best known:—

F. communis.—A noble plant 8-12 ft. high, native of the Mediterranean region, with finely cut, needle-like, flaccid leaves, the upper ones with very large sheaths. Flowers in June, yellow; cen-

tral umbel nearly sessile; side ones small, stalked; involucre wanting.

Culture &c. as above.

F. glauca.—A beautiful plant 6-8 ft. high, native of S. Europe. Leaves glaucous beneath, with linear, elongated, flat leaflets. Flowers in June, yellow; side umbels on longer stalks than the central one; involucre absent.

Culture &c. as above.

F. tingitana.—A native of N. Africa 6-8 ft. high. Leaves shining, with deeply toothed, oblong lance-shaped leaflets. Flowers in June; side umbels few, on longer stalks than the central ones.

Culture &c. as above.

HERACLEUM (COW PARSNIP; HAG-WHEED).—A genus containing 70 species of tall, strong, coarse-growing, more or less hairy biennial or perennial herbs, with large, broadly lobed, pinnate or ternately dissected leaves, and flowers in large, compound, many-rayed umbels. Calyx teeth absent, or more or less conspicuous. Petals wedge-shaped, rhomboid, or clawed, notched or deeply 2-lobed, points incurved. Fruit roundish obovoid or oblong-flattened.

Culture and Propagation.—Heracliums are essentially plants for the wild garden. They will grow in any poor soil and seem to be as much at home among brick rubbish as on the banks of streams or ponds. They may be increased by seeds sown in the open border when ripe or in spring, or by division in early autumn or spring, but will reproduce themselves from seed if left alone.

Some very fine plants of *H. giganteum* (or *villosum*)—the 'Cartwheel Flower'—were growing in June 1899 among the rubbish around Westminster Cathedral, London. They were 6-10 ft. high, with green and purplish stems 2-3 in. in diameter, with large lobed spreading leaves. Many of the umbels of white flowers were as much as 18 in. across, the stalks of each little umbel radiating upwards from the main stalk like the spokes of a wheel or the ribs of an umbrella turned inside out.

There are several other species, such as *setosum*, *sibiricum*, *eminens* &c., but they are somewhat confused, and none have such a fine aspect as *giganteum*, although the Persian *H. persicum* and the Caucasian *H. pubescens* are also noble-looking plants.

LVI. ARALIACEÆ—Ivy Order

An order containing about 40 genera and 340 species of erect or climbing trees or shrubs, rarely herbs, often clothed with a starry down, occasionally spiny. Leaves alternate or rarely opposite, entire, toothed, lobed, or palmately or pinnately divided. Stipules various, rarely none. Flowers regular, hermaphrodite, polygamous, or rarely dicecious, in heads, umbels, racemes, or panicles. Calyx tube adnate to the ovary. Petals 3 or more, often 5, usually valvate. Stamens as many as petals, rarely more. Ovary inferior, 1- or more celled. Fruit a drupe or berry.

ARALIA.—A genus containing about 30 species of smooth or downy, bristly or spiny shrubs or herbs. Leaves alternate, digitate, or once or more pinnately cut with serrulate leaflets. Flowers often polygamous-monoecious, in umbellate racemes or panicles, rarely in compound umbels. Calyx shortly 5-toothed. Petals 5, ovate, obtuse, or very shortly incurved at the tip, more or less imbricate at the edges. Ovary 2-5-celled. Fruit compressed, 3-5-angled, containing 2-5 stony seeds.

Culture and Propagation.—The

species described below are the only ones more or less hardy in the British Islands. They thrive in a deep, rich, well-drained loam, and should be planted in sheltered sunny spots. In northern parts the plants may require protection with a little canvas or matting in hard winters. They have a very graceful and ornamental aspect, and lend a somewhat tropical appearance to the garden. Most of the species may be increased by seeds sown as soon as ripe or in spring in cold frames; or by root and stem cuttings 2-3 in. long in sandy soil in heat in early spring. Some kinds

produce suckers freely, and these may be detached with as many roots as possible, and replanted in mild showery weather either in early autumn—say in September—or in spring.

A. cachemirica (*A. macrophylla*).—A Himalayan herbaceous perennial about 6 ft. high, with very large compound leaves, the hairy leaflets of which are 4–5 in. long and tapering to a point. The umbels of white flowers appear in summer and are arranged in a narrow terminal raceme 3–4 ft. long.

Culture &c. as above. Increased by seeds. Requires warm sunny situations.

A. chinensis.—When this species is well furnished with its leathery pinnate leaves, it is a very handsome shrub. It is a native of China and grows 6–12 ft. high, and in favourable situations considerably more. The flowers are creamy-white, in umbellate panicles, and add a beauty to the plant in July and August. *Dimorphanthus mandshuricus* is another name for it, and there is a variety called *canescens* with very hairy and prickly leaves 3–5 ft. long. A new variety with an irregular silvery bordering to the leaves has recently appeared.

Culture &c. as above. This plant enjoys warm and moist situations and may be grown near ponds, streams &c., where the roots are likely to secure an abundance of moisture.

A. edulis.—A hairy and spineless Japanese perennial 4–6 ft. high. Lower leaves pinnate, with about 5 leaflets; upper ones with stalked, finely toothed, downy leaflets. Flowers in summer, white, numerous, in rounded umbels. This is also known as *A. cordata*.

Culture &c. as above. Grows well in shade.

A. nudicaulis.—A native of North America 3–4 ft. high. Lower leaves pinnate, with 5 oblong-oval, tapering, serrate leaflets. Flowers in June, greenish, each division of the trifid scape bearing a many-flowered umbel.

Culture &c. as above. This herbaceous species grows well in shade and may be increased by division or from seeds.

A. racemosa.—A highly ornamental N. American herbaceous plant 3–4 ft. high. Leaf stalks 3-parted, each one bearing 3–5 ovate or heart-shaped, pointed, serrated, smoothish leaflets. Flowers in

June, greenish-white, in terminal umbellate racemes.

Culture &c. as above. Increased by seeds or division. Grows well in shade.

A. spinosa (*Angelica Tree*).—A fine N. American shrub 8–12 ft. high, with simple prickly stems, forming an umbrella-like head. Leaves twice and thrice pinnate, with ovate pointed, deeply serrated leaflets. Flowers in autumn, small, white, in large panicles.

Culture &c. as above. Suckers are freely produced and may be utilised for increasing the plants.

ACANTHOPANAX.—A small genus of smooth or woolly shrubs or small trees closely related to the Aralias and often called by that name in gardens. The leaves are usually palmately lobed. Flowers polygamous or hermaphrodite. Petals and stamens 5, rarely 4.

Culture and Propagation.—The remarks made under Aralia are equally applicable to Acanthopanax. The plants like a deep rich and well-drained loam and warm sheltered situations fully exposed to the sunshine. They may be increased from seeds, cuttings of the roots, or ripened shoots, and also by suckers from the base.

A. ricinifolium (*Aralia Maximowiczii*). An elegant Japanese shrub with erect spiny stems, said to reach a height of 90 ft. in the forests of Yezo. Leaves long-stalked, palmately 5–7-lobed like those of the Castor Oil plant (*Ricinus*); lobes 3½ in. long, lance-shaped, serrate.

Culture &c. as above. This is a very striking plant and quite hardy as far north as the Thames Valley.

A. sessiliflorum.—A recently introduced species native of China and Japan. It has roughish dark green wrinkled leaves cut into 3–5 lobes. The small dull purple flowers with protruding stamens appear in summer and are closely packed into a roundish sessile head at the ends of the shoots.

Culture &c. as above.

A. spinosum (*Aralia pentaphylla*).—This must not be confused with the North American *Aralia spinosa* described above. It is a native of China and Japan, and in cultivation becomes a small shrub with prickly stems. The deep green leaves are cut into 3–5 ovate lance-shaped segments 2–3 in. long, with serrate margins, and

constitute the chief attraction of the plant. The variety *variegata* has the leaves broadly edged with creamy white.

Culture &c. as above.

FATSIA.—A small genus closely related to *Acanthopanax*, and like that often called *Aralia* in gardens. The flowers are polygamous or hermaphrodite. Petals 4-6, membranous. Stamens 4-6.

Culture and Propagation.—The *Fatsias* are well known chiefly through *F. japonica* described below. They may be cultivated in the open air in the same way as the *Aralia* and *Acanthopanax*, in deep rich well-drained soil, and in warm sheltered spots. They are increased by seeds sown under glass, and by cuttings of the stems and roots.

F. horrida.—This rather tender shrub is a native of the Rocky Mountains and also Japan. The stems and leaf stalks are thickly covered with sharp spines—a circumstance that suggested the specific name, and the leaves are palmately lobed and densely covered with prickles on the midrib and principal veins.

Culture &c. as above. This plant requires a warm well-drained soil and positions sheltered from bleak winds. Too much moisture at the root in winter is very injurious, but during the spring and summer months plenty of water may be given.

F. japonica (*Aralia Sieboldi*).—A beautiful Japanese evergreen shrub 3-5 ft. high, with large, leathery, digitate, shining green leaves.

Culture &c. as above. This plant is usually grown in greenhouses, and thousands are raised every year from seeds sown in spring in heat. The tops of the seedlings are often taken off as cuttings and rooted, and make very fine symmetrical plants. Large specimens look well on lawns in semi-shady places. Not quite hardy in severe winters except in the mildest parts of the country. There are beautiful silver and golden variegated forms less hardy than the type.

F. papyrifera (*Aralia papyrifera*).—*Chinese Rice-paper Plant.*—A handsome Formosan shrub 6-8 ft. high, and practically hardy in sunny spots in the southern parts of the country. Protection from frost is required in northern localities. The leaves are 8-12 in. long, 5-7-lobed, downy when young, smooth when old.

Flowers greenish in drooping panicles 2-3 ft. long.

Culture &c. as above.

HEDERA (Ivy).—Botanically there are only 2 species of Ivy—the Australian (*H. australiana*) and the British (*H. Helix*). It is the latter and its numerous varieties that are so well-known in cultivation. The essential characters of the genus are:—climbing evergreen shrubs, with simple, undivided, lobed (or pinnate in *H. australiana*) leaves. Flowers polygamous in paniculate umbels. Calyx entire or 5-toothed. Petals 5, valvate. Stamens 5. Ovary 5-celled, styles united in a cone or short column.

The uses to which Ivy can be put are numerous. As a rule the common Ivy (*H. Helix*) and its green-leaved forms are more vigorous than the silver or golden forms. Covering old walls, old stumps of trees, decorating stone pillars of gateways, the sides of buildings, or under trees where nothing else will grow, are a few of the many ways in which Ivy may be appropriately used.

Culture and Propagation.—Although not particular as to soil, Ivy grows much better in good rich sandy loam than in poorer soil, and it covers any required space in a much quicker period.

Increase of the commoner sorts is very easy, especially where roots are freely produced on the stem. Pieces any length, if placed on the soil and covered over or pegged down here and there in the autumn, will readily root, and begin to grow freely the following spring. The Tree Ivies are usually grafted on stocks of a baser kind, and all rare and special varieties are usually increased by this means under glass, as it is quicker and more sure than by cuttings. Of late years Tree Ivies have become more popular, and in appropriate positions make fine bushes in the garden.

Below is a description of *Hedera Helix* and some of its best varieties:—

H. Helix (*Common Ivy*).—A native of the British Islands, Western and S. Europe, N. Africa, and West Central Asia. Leaves thick and shining, ovate, angled or 3-5-lobed; those of the flowerless stems usually much more divided than the others. Flowers in autumn, yellowish-green, succeeded by umbellate clusters of roundish fruits.

var. algeriensis (*H. canescens*, H

viridis).—A beautiful quick-growing variety, with large yellowish-green leaves varying from entire, broadly ovate or roundish, to a peculiar 3-lobed form. There is a variegated form of this.

var. arborescens (Tree Ivy).—An arborescent form of the Common Ivy. There are forms with golden and silver variegation, and also one with yellow berries.

var. canariensis (H. grandifolia).—Irish Ivy.—Leaves deep green, usually 5-lobed, terminal lobe largest. This is excellent for quickly covering walls, or bare ground under trees, or wherever anything else will not grow. The branches which produce flowers and fruit have ovate entire leaves. There are gold and silver variegated forms of the Irish Ivy, known respectively as *aureo-maculata* and *foliis argenteis*.

var. chrysoarpa.—A quick-growing climber with smallish, almost triangular or 3-lobed leaves, central lobe often prolonged with a few sharp lobes or notches; colour grey-green, with veins of a lighter shade. The variety *aurantiaca* is similar, but has yellow fruits.

var. conglomerata.—A distinct, slow-growing, erect variety, with small wavy leaves, and short internodes. Excellent for rambling over rockwork.

var. cuspidata minor.—A pretty variety with purplish stems and leaf stalks, and small uniformly 3-lobed and crenated leaves, of a rich glossy green, with whitish veins.

var. deltoidea.—A distinct Ivy with stout, purplish stems, and bluntly deltoid blackish-green leaves, changing to a dull purple-bronze in autumn. Suitable for walls.

var. dentata.—A large handsome form with leathery, heart-shaped, glossy leaves, sometimes distinctly toothed.

var. digitata.—A strong-growing Ivy with finger-shaped, blackish-green leaves, with whitish veins. Excellent for walls. The variety *caenwoodiana* is very similar if not identical with this.

var. donerailensis.—A very pretty form with small 3-lobed leaves, which assume a dull purple-brown in winter.

var. Glymi.—A distinct, wiry-growing form, with leaves varying from ovate to long wedge-shaped, many being obscurely 3-lobed, of a very glossy, deep, dull green. This variety is also known as *tortuosa*.

var. gracilis.—A graceful variety,

with wiry, purplish stems, and 3-lobed leaves, light dull green changing to rich bronze in autumn. Good for covering walls, pillars, old stumps &c.

var. lobata major.—A strong, free-growing variety with deep glossy green, 3-5-lobed leaves.

var. lucida.—A quick grower, with deltoid or 3-5-lobed glossy leaves.

var. luteola.—A fine, strong-growing Tree Ivy, with broadly ovate, irregularly rhomboid, sometimes 3-lobed leaves, green in the centre, mottled with grey, and broadly edged with creamy yellow.

var. marginata.—A rather slow-growing variety with bluntly triangular leaves, dull green, edged with creamy white, brightly striped with red or pink in autumn.

var. marginata aurea has elongated triangular leaves, edged with pale orange-yellow, turning to red. Good wall Ivy.

var. marginata minor (H. Cavendishi).—Leaves smaller than in *marginata* proper; rather a slow grower, with weak stems.

var. marginata rubra (H. elegantissima; H. tricolor).—Leaves like those of *marginata* in shape, but with deep rosy-red edges in autumn. The colour disappears in spring. There is also a form called *marginata purpurea*.

var. marmorata.—A fine large-leaved form with irregular creamy-white blotches. The sub-variety *minor* is distinct, with smaller leaves.

var. palmata.—Leaves 3-5-lobed, dull, deep green, very much like *digitata* when young.

var. pellucida.—A vigorous variety, with red stems when young. Leaves bluntly 4-angled, mottled with green and white.

var. purpurea.—A climbing form with leathery leaves of a purplish colour, like *rægneriana*.

var. rægneriana.—A handsome vigorous form, with broadly heart-shaped, leathery, dark green leaves. The tree form is very striking.

var. rhombea.—A distinct form with medium-sized, rhomboid leaves, green, narrowly edged with creamy white.

var. sagittæfolia.—A free-growing, wiry-stemmed variety, usually with bluntly 3-lobed leaves, the central lobes projecting, sharply triangular; colour deep dull green, with a few blackish-

bronze blotches, changing to rich purple-bronze in autumn.

var. sartifolia (H. cordata).—A distinct but not strong-growing variety, with roundish, triangular, or obscurely 3-lobed, dull green leaves, with obscure veins.

var. variegata.—A beautiful form of the Common Ivy with light green leaves, edged and blotched with creamy-white.

var. willsiana (H. nigra).—A dark-leaved form near *lobata major*, but much darker in colour in summer, and in winter almost black; veins less distinctly marked.

In catalogues many other names will be found, but as a good deal of confusion exists with the names, it is better to see the actual plants than to buy from catalogue descriptions.

LVII. CORNACEÆ—Dogwood Order

A genus consisting of 12 genera and 75 species of smooth or silky-haired trees or shrubs. Leaves opposite, or alternate, often stalked, leathery, entire, or occasionally lobed, angled, or serrate. Stipules none. Flowers usually small, regular, unisexual or hermaphrodite. Calyx-limb 4-5-toothed or lobed. Petals none, or 4-5, rarely more. Stamens 4 or 5. Ovary inferior, 1-4-celled. Fruit often drupe-like, with 1-4 stony seeds.

CORNUS (CORNEL; DOGWOOD).—This genus contains about 25 species of trees or shrubs, rarely herbs, with opposite, rarely alternate, stalked or nearly sessile, entire, or somewhat serrulate leaves, often glaucous beneath. Flowers hermaphrodite. Calyx-tube more or less bell-shaped, round, angled, or ribbed. Petals 4, oblong or ovate. Stamens 4. Disc cushion-like, or absent. Drupe ovoid or oblong.

All the shrubby Dogwoods are useful for shrubberies, and some of them look well in groups on grass against which the deep purple leafless stems look beautiful even in winter. The ground beneath may be carpeted with such dwarf and early-flowering plants as the Winter Aconite, Snowdrops, Crocuses, Scillas &c. to give a brightening effect to the surroundings.

Culture and Propagation.—They may be increased by seeds, layers, suckers, or cuttings in the autumn. The seeds may be sown in cold frames, and when well germinated the following spring the seedlings may be pricked out into light rich soil. Cuttings of the ripened shoots also root readily in most cases under a hand-light in autumn, but any that refuse to be increased in this way may be layered, or suckers from the base may be detached and replanted. *C. canadensis* and *C. suecica* are herbaceous and not shrubby kinds and require somewhat different treatment. They thrive in sandy peat, in rather shady spots; and are easily increased by dividing the roots in early autumn. The other

species grow well in rich well-drained loam and are benefited by an annual mulching of well-rotted manure in autumn or winter.

C. alba (*White-Fruited Dogwood*).—A native of N. Asia and Siberia, about 10 ft. high, with slender, reddish branches and creamy-white flowers, succeeded by white fruits. The variety *Späthi* has beautiful bronzy leaves in spring, changing to green with an irregular gold margin in summer. *Gouchalti* is another variegated form. *Sibirica* is a dwarf variety with bright-coloured branches, and it also has a variegated form.

Culture &c. as above.

C. alternifolia.—A rare N. American species 20-30 ft. high, in a wild state, and on damp ground. Full-grown trees make beautiful pyramids, the branches of which spread out horizontally in tiers and are clothed with deep green bark. As may be seen from the characters of the genus given above, the leaves of most of the Dogwoods are opposite, but in this species, as the name indicates, they are alternate. It has pale yellow flowers, and bluish-black berries borne on bright red stalks.

Culture &c. as above.

C. asperifolia.—Also a native of N. America, with reddish-brown bark, small hairy leaves, and pearly white berries on reddish stalks.

Culture &c. as above. This species grows naturally in dry sandy places and likes warm sunny positions in our gardens.

C. californica.—A Californian species about 10 ft. high with smooth branches, hairy branchlets, and cymes of pretty white flowers, succeeded by white berries.

Culture &c. as above.

C. canadensis (*Bunch Berry*; *Dwarf Cornel*).—A small N. American herbaceous plant 4–8 in. high, with upper leaves in whorls, ovate pointed, veined, on short stalks. Flowers in May, purplish-white, umbellate, shorter than the 4 white, ovate, pointed bracts. Berries red, conspicuous, sweet and palatable.

Culture and Propagation.—This is a suitable plant for the bog garden, or cool parts of the rockery. It may be easily increased by dividing the roots in early autumn.

C. capitata (*Benthamia fragifera*).—*Strawberry Tree.*—A beautiful tree native of N. India and China, often reaching a height of 40 ft. in Devonshire and Cornwall, and the S. of Ireland, the only parts where it appears to be hardy. Leaves 3–4 in. long, lance-shaped, pointed at each end, shortly stalked, roughish, with small adpressed down. Flowers from June to October, large, white, sessile, densely clustered in a round head. Fruit about the size of a very large Strawberry, clear red, composed of many more or less hexagonal fleshy drupes.

Culture &c. as above.

C. circinata (*Round-Leaved Dogwood*).—A native of the United States, 3–10 ft. high, with purple-greenish, warty branches, and large, roundish, oval, abruptly pointed leaves, 4–5 in. long, covered with hoary down beneath. Flowers in June, white, in flat cymes. Berries bright blue, about the size of a Pea.

Culture &c. as above.

C. florida (*Flowering Dogwood*).—A beautiful tree, 20–30 ft. high in the United States, with a very bitter bark. Leaves ovate pointed, with adpressed hairs on both surfaces, changing to shades of green, brown, buff, and yellow in autumn. Flowers in April and May, greenish-yellow, with 4 large white orbicordate bracts. There is a form (*flore rubro*) in which the flowers are tinted with bright red.

Culture &c. as above. Only in the hottest parts of the country does *C. florida* grow to the best advantage, as the pro-

duction of its fine flowers depends upon the thorough ripening of the wood.

C. Kousa (*Benthamia japonica*).—A beautiful Japanese species 3–8 ft. high, with ovate lance-shaped leaves, and clusters of small yellowish flowers, which, however, are surrounded by 4 large white ovate pointed bracts much more attractive in appearance and each about 1½ in. long. They appear in May and June.

Culture &c. as above.

C. macrophylla (*C. brachypoda*).—A Japanese species of moderate size, with crimson-stalked, elliptic ovate, green-leaves, which change to brown tinted with rose in autumn. Flowers in early summer, white, in clusters. There is a variegated form, with white-edged leaves, but it is not particularly striking.

Culture &c. as above.

C. Mas (*C. mascula*).—*Cornelian Cherry.*—A beautiful free-growing Austrian species 10–15 ft. high, with oval-pointed leaves, rather downy on both surfaces. Flowers from February to April, yellow, appearing before the leaves, in umbels about equal in length to the 4-leaved involucre. The variety *variegata* has leaves variegated with silvery white; and *elegantissima* has the foliage beautifully marked with creamy white and tinged with red. Other forms are *aurea*, *fructu violaceo*, *lanceolata*, *nana* (or *pumila*), and *xanthocarpa*. Old trees flower and fruit freely, the fruit being an inch or more long, Cherry-like, bright red, yellow or violet. *C. officinalis* from Japan and Corea resembles the Cornelian Cherry in appearance, but may be easily distinguished by the tufts of rusty-coloured hairs in the axils of the main veins of the leaves.

Culture &c. as above.

C. Nuttallii.—A native of the forests of California and Oregon, where it attains a height of 50–60 ft., with leaves like those of *C. florida*. The flowers are surrounded usually by 6 large broad white bracts, each 2–3 in. long.

Culture &c. as above. Seedlings of this species are best grown on under the protection of cold frames for a year or two until comparatively large and sturdy, before planting in the open border.

C. paniculata.—A native of the United States 4–8 ft. high, with pale purple branches. Leaves ovate, pointed,

smooth, hoary beneath. Flowers in July and August in loose cymes. Fruit white.

Culture &c. as above.

C. pubescens.—This shrubby Dogwood grows 4–12 ft. high, and is a native of Western N. America. It has smooth purplish branches more or less covered with hairs, and oval or ovate-acute leaves, green above, silky white beneath. The white flowers appear in summer, and are succeeded by white fruits.

Culture &c. as above.

C. sanguinea (*Common Dogwood*; *Dogberry*; *Prickwood*).—A native of Britain and north temperate regions, 6–8 ft. high, with dark red branches. Leaves 2–3 in. long, ovate, or ovate oblong, acute, downy. Flowers in June and July, creamy white, in dense terminal cymes, succeeded by small black berries. The variety *candidissima* has pale yellowish-green bark; *latifolia* has much broader leaves than the type; and *variegata* is an undesirable form with variegated foliage.

Culture &c. as above.

C. sericea.—A native of the United States 5–8 ft. high, with woolly branchlets, having a dull purple-coloured bark and ovate pointed leaves, clothed with rusty down beneath. Flowers in summer, white, in woolly depressed corymbs. Berries pale blue, roundish.

Culture &c. as above. This species prefers rather moist and boggy situations and may be grown on the banks of streams, ponds &c.

C. stolonifera (*Red Osier Dogwood*). A North American species 4–10 ft. high, spreading and increasing freely by prostrate or underground stems. Young shoots bright reddish-purple. Leaves ovate acute, downy, whitish beneath. Flowers in May, white, in small flat cymes. Berries white. *C. Baileyi*, a recently introduced Dogwood, native of S. Canada, is closely related but may be distinguished from this species by its erect habit, by the absence of creeping underground stems, by the duller brownish bark, the pearly-white fruits, and the white wooliness of the under surface of the leaves.

Culture &c. as above for *C. sericea*.

C. stricta.—A straight-growing species 8–15 ft. high, native of the United States, with reddish-brown branches. Leaves ovate, pointed, smooth, green on

both sides. Flowers in June, white, in loose, flattish cymes. There is a form with white and yellow variegated leaves. The type is also known as *C. candidissima*.

Culture &c. as above.

C. succica.—A native of Britain and Northern Europe, about 6 in. high, with opposite, sessile, ovate leaves. Flowers in June, dark purple, with 4 white bracts, which finally change to green. Berries red.

Culture and Propagation.—Like *C. canadensis* this herbaceous species may be grown in swampy or cool moist places and may be increased by dividing the roots in early autumn. It will also flourish in ordinary garden soil which is not particularly moist.

AUCUBA.—A genus of beautiful evergreen shrubs with opposite leaves, and small diœcious flowers in axillary panicles. In the male flowers the calyx is small, 4-toothed. Petals 4, ovate or lance-shaped. Stamens 4. Disc 4-angled, fleshy. Ovary none. Female flowers:—Calyx tube ovoid or nearly cylindrical, 4-toothed. Fruit a 1-seeded drupe about the size of the Sloe.

A. japonica.—A native of Japan 6–10 ft. high, with broadly ovate-lance-shaped leaves, pointed, toothed, leathery in texture, smooth and shining, pale green spotted and mottled with yellow. There are numerous more or less distinct forms of both the male and female kinds, all worth growing. *A. himalaica*, from the Himalayas, is probably a geographical form of *A. japonica*. A large-leaved form of it called *macrophylla* has orange-coloured berries. The distinct features of the following varieties are sufficiently indicated by the names: *albo-variegata*, *avrea*, *dentata*, *latimaculata*, *latifolia*, *angustifolia*, *pygmæa*, *salicifolia*, *sulphurea*, and *viridis*.

Culture and Propagation.—Aucubas are excellent shrubs for growing where others will not, as under trees. The pollen-bearing plants (*i.e.* those having stamens) should be planted near the others so that a good crop of bright red berries may be always relied upon. One male or pollen-bearing plant in the vicinity of several female or pistillate ones will be sufficient to ensure fertilisation by natural means. Where this is not the case, the crop of berries may be improved by collecting the pollen, and dusting it with

a camel-hair brush on to the pistil when the tip of the latter is in a sticky condition.

Aucubas thrive in any garden soil, and may be increased by cuttings inserted in light sandy soil in spring or autumn in shady borders; or from seeds sown as soon as ripe in pans or boxes in cold frames. The lower branches may also be layered during the summer months and detached in autumn or spring when well rooted.

GARRYA.—A genus containing about 8 species of shrubs with 4-angled branches, and opposite entire or denticulate evergreen leaves. Flowers dioecious, in slender drooping catkins. Petals none. Stamens 4. Ovary 1-celled; styles 2. Berry ovoid, 1-2-seeded.

G. elliptica.—A beautiful Californian evergreen 8-10 ft. high, with elliptic, dark shining green leaves, hoary beneath. Flowers in mild winters as early as December, pale greenish-white or yellowish in drooping catkins so much like slender tassels that the name Tassel-bush has been suggested as a popular name. Berries black. The pollen plant is more elegant than the berry-bearing one.

Culture and Propagation.—This is the only species at present generally grown. In warm situations it makes a beautiful bush; but it is often grown on a wall. In cold localities it requires shelter. The plants thrive in rich sandy loam, and may be increased by seeds, or cuttings of the half-ripened wood inserted in sandy loam in August, and shaded from the sun until rooted. Also by budding or grafting on stocks of *Aucuba japonica*, and by layering the shoots in autumn, and detaching in spring when well rooted.

GRISELINIA.—A genus with 8 species of trees or shrubs, having alternate, often unequal-sided, oblong, nearly quadrate or lance-shaped, thick leathery entire leaves, spiny-toothed or angled. Flowers dioecious, in terminal panicles. Calyx teeth, petals, and stamens 5 in the male flowers. Berry ovoid.

Culture and Propagation.—Grise-linias thrive in light rich loam, and may be increased by cuttings or layers like *Aucubas*. Both the species described below are natives of N. Zealand.

G. littoralis.—This grows 30 ft. high in a wild state. It has ovate or oblong leathery and glossy leaves, which remain

on the plant during winter. It is a good plant for seaside places and seems to be hardy in the mildest parts of the country.

Culture &c. as above.

G. lucida.—Grows 10-12 ft. high, with obliquely ovate, unequal-sided leaves, distinctly veined beneath, and of a shining green above. The variety *macrophylla* is chiefly distinguishable from the type by its larger leaves.

Culture &c. as above.

NYSSA (TUPELO TREE).—A genus of more or less silky haired deciduous trees or shrubs with alternate stalked leaves which are entire or lobed or toothed when young. The small polygamous-dioecious flowers are borne in crowded heads, or short racemes at the ends of the axillary stalks. The male flowers have a somewhat cup-shaped calyx with 5 or more teeth. Petals and stamens 5 or more. Disc large, cushion-like, entire or lobed. The female flowers have a more or less bell-shaped calyx with 5 teeth. Petals none or very small. Stamens none, or rudimentary. Ovary 1-celled. Fruit an oblong drupe.

Culture and Propagation.—The Nyssas are rather handsome trees, but are very rarely seen outside botanic gardens. They are chiefly valuable for the autumn colouring of the foliage, which becomes a deep scarlet tint, and looks very fine wherever a good specimen is growing. The plants flourish in moist or marshy peat spots and may be planted near the edges of lakes, streams, ponds &c. Seeds do not often ripen in cultivation, but the plants may be increased by layering the branches in late summer or autumn.

N. aquatica (Water Tupelo).—A native of the Southern United States, where it attains a height of 30-50 ft. It has oval oblong entire leaves 3-4 in. long, glaucous beneath, and tinged with red in autumn. The flowers appear in April and May, and are succeeded by pairs of dark blue obovoid drupes about the size of a pea.

Culture &c. as above.

N. capitata (Ogeechee Lime).—This is also a native of the South United States, and grows about 30 ft. high. The leaves are more or less oval or oblong and downy beneath, and the flowers appear in April and May. The red Plum-like fruits appear in due course and are of an agreeably acid flavour.

Culture &c. as above.

N. sylvatica (*N. multiflora*).—*Black or Sour Gum; Pepperidge*.—A North American tree, 30–50 ft. high, with a habit somewhat resembling that of the Beech. The deep green oval leaves, 2–4 in. long, are downy when young but smooth when old, and are then remarkable for their brilliant crimson hues, which look effective. The flowers appear in May, and are succeeded by deep blue fruits.

Culture &c. as above. This species

flourishes in deep rich loam, and will also grow slowly in poor gravelly soils.

N. uniflora.—A native of the swamps of Florida, where it grows 70–90 ft. high. The long-stalked oval tapering leaves, with 2–3 teeth on one side, are 5–6 in. long, and downy beneath. The small solitary flowers appear in May, and are succeeded by large deep blue fruits.

Culture &c. as above. This is the tallest of the Tupelo trees, but does not appear to be quite so hardy as the others.

Division II. GAMOPETALOUS DICOTYLEDONS

Series I. EPIGYNÆ (see p. 125).

LVIII. CAPRIFOLIACEÆ—Guelder Rose Order

An order consisting of 14 genera and about 200 species of shrubs or herbs with opposite, simple, or compound leaves and no stipules. Flowers usually corymbose or cymose, and often sweet-scented. Calyx-limb superior, 3–5-toothed or lobed, usually with 2 or more bracts at the base. Corolla regular or irregular, gamopetalous or polypetalous, often 2-lipped. Stamens 4–10, epipetalous. Fruit a berry, drupe, or dry capsule.

SAMBUCUS (ELDER).—A genus containing 10–12 species of ornamental trees or shrubs, rarely herbs, with pinnate leaves, and large compound cymes of small white, yellow, or pinkish flowers. Calyx limb 3–5-lobed or toothed. Corolla rotate or somewhat bell-shaped, with 3–5 usually imbricated lobes. Stamens 5. Fruit a berry-like drupe with 3–5 one-seeded stones.

Culture and Propagation.—The Common Elder (*S. nigra*), as everyone knows, grows well in any soil with plenty of sunshine above and moisture beneath. Its more ornamental varieties and other species do equally well under similar conditions, and when judiciously planted lend a charm to the landscape. Herbaceous kinds like *S. Ebulus* may be increased by dividing the rootstocks in early autumn or spring. The shrubby kinds increase easily from cuttings inserted in sandy moist soil in shade. Seeds also germinate freely, not only in the case of the Common Elder, but also the others. They may be sown as soon as ripe out of doors in the milder parts of the country, or in cold frames in more unfavourable localities.

S. canadensis.—A handsome Canadian Elder 6–12 ft. high, with pinnate leaves composed of 4–5 pairs of leaflets and an odd one, the lowest pair being often cut into two or three lobes. The whitish flowers appear about June and July, and are borne in long-stalked flattish clusters, being afterwards succeeded by purple-black fruits.

Culture &c. as above. A good plant for placing near the margins of lakes, streams &c.

S. Ebulus (*Dane's Blood; Dwarf Elder &c.*).—A native of Europe, temperate Asia and N. Africa, and also the British Islands, whither it is supposed to have been introduced by the Danes. It has stout ribbed and grooved herbaceous stems 2–4 ft. high, and leaves with 4–6 pairs of oblong-lance-shaped, serrate leaflets 4–6 in. long. Flowers in July and August, white tipped with pink, in cymes 3–4 in. across. Berries small, globose, black. This plant, which emits a somewhat obnoxious smell when bruised, is useful for rough shrubberies, banks &c. It may be increased by dividing the roots in early autumn or in spring.

Culture &c. as above.

S. glauca (*S. californica*).—A beautiful Elder, native of California and other parts of Western America, where it grows 30–50 ft. high. It very much resembles our Common Elder (*S. nigra*) in the foliage, having lance-shaped serrate leaflets. The whitish flowers appear in early summer, and are succeeded by blackish fruits which are remarkable for the thick bluish-white bloom that covers the surface, and suggested the specific name.

Culture &c. as above.

S. nigra (*Common Elder*; *Boon Tree*; *Bur Tree*).—A well-known British tree 20–25 ft. high, having leaves divided into 2–4 pairs of ovate-oblong, or lance-shaped, serrate leaflets 1–3 in. long. Flowers in May and June, white, in flat-topped cymes 4–6 in. across, succeeded by small black berries, so much used for making Elderberry Wine in many parts of the country.

There are several fine-leaved varieties, among which may be mentioned:—*foliis aureis*—the Golden Elder, with yellow leaves. A beautiful plant which may be kept dwarf and bushy by pinching out the tips of the young shoots; *laciniata*—Parsley-leaved Elder, a handsome form with finely cut leaves; *monstrosa*, with the flowers increased in parts, branches striped, and fruits irregular; *rotundifolia*, with trifoliate leaves and roundish leaflets. There are also silver and golden variegated-leaved forms, and forms with white (*leucocarpa*), and yellowish-green fruits (*virescens*).

Culture &c. as above.

S. racemosa (*Hart's Elder*; *Scarlet-Berried Elder*).—A large shrub 10–20 ft. high, native of S. Europe and Siberia, with large pinnate smoothish pale green leaves; leaflets 5, oblong pointed, serrated, unequal at the base. Flowers in April and May, white, in panicles, succeeded by scarlet fruits in favourable places. The variety *serratifolia* is an elegant shrub with deeply cut serrated leaflets. There are also forms called *laciniata* with jagged leaflets, and *plumosa* with deeply pinnatifid ones. The variety *foliis aureis* has yellow foliage; *rosaflova* has deep pink or purple-tinted blossoms; *spectabilis* has purer white flowers than the type; and *tenuifolia* is a handsome form with the leaf segments cut into narrow strips.

Culture &c. as above.

VIBURNUM.—A genus containing about 80 species of ornamental, deciduous or evergreen trees and shrubs, with opposite, rarely whorled leaves, stalked, entire, serrate or toothed, always simple, with or without stipules. Flowers white or pinkish, jointed on the pedicels, in terminal or axillary cymes, corymbs, or panicles, hermaphrodite, or the outer ones much larger and sterile (as in *Hydrangea*). Calyx-tube turbinate or ovoid; limb short, equally 5-toothed. Corolla regular, rotate, bell-shaped or tubular, with 5 equal imbricated lobes. Stamens 5, epipetalous. Fruit a 1-seeded, dry or fleshy, round or flattened drupe.

Culture and Propagation.—Most of the Viburnums are easily grown in any fairly good soil with plenty of moisture at the root in summer. They are increased by layers; or by cuttings of the half-ripened young shoots inserted in sandy soil in a cold frame, or under handlights in a shady place. In autumn or winter a little pruning or thinning out of dead or useless branches may be needed, and a good top-dressing of manure will be highly beneficial to the plants.

The genus is familiar to almost every one by means of the Snowball Tree or Guelder Rose (*V. Opulus*) and the Laurustinus (*V. Tinus*). But there are several other fine species in cultivation, all worth growing either in borders or shrubberies, or in groups by themselves on grass &c.

V. acerifolium (*Dockmackie*).—A pretty compact shrub about 4 ft. high, native of the N.E. United States. Leaves roundish, Maple-like, somewhat coarsely toothed and 3-lobed, downy beneath, 4–5 in. across, becoming a bright claret colour in autumn. Flowers in May and June, white, on slender stalked cymes 2–3 in. across, with very few sterile blossoms, or none. Fruit black, oval.

Culture &c. as above.

V. cassinoides.—A compact shrub about 6 ft. high, native of swampy places in N. America. Leaves 3–4 in. long, thick, leathery, ovate-oblong. Flowers in June, yellowish-white, in flat cymes 4–5 in. across. Fruit handsome, rosy at first, changing to bluish-black.

Culture &c. as above.

V. coriaceum.—A recently introduced Chinese species with dark evergreen leaves, 3-5 in. long, pointed, smooth, distantly toothed, somewhat resembling those of a green Aucuba. Flowers in summer, white, almost tubular, in small terminal corymbs.

Culture &c. as above.

V. cotinifolium (*Indian Wayfaring Tree*).—A pretty Himalayan shrub 5-10 ft. high, with ovate or elliptic leaves, almost entire, rarely coarsely crenate, usually woolly beneath. Flowers in June, white, in dense terminal corymbs 2-3 in. across.

Culture &c. as above.

V. dentatum (*V. montanum*).—*American Arrow Wood*.—A handsome shrub 5-10 ft. high, native of the Eastern United States. Leaves 2-4 in. across, broadly ovate or roundish, strongly veined, deeply and regularly toothed, often bearded in the axils of the veins. Flowers in June, white, all small and fertile, in terminal cymes 3-4 in. across. Fruit dark blue or purple, small, ovoid, rarely ripened in this country. There is a variegated form.

Culture &c. as above.

V. dilatatum.—A handsome Japanese shrub 6-10 ft. high. Leaves 3-5 in. long, varying from roundish to obovate, usually abruptly and bluntly pointed, coarsely and unevenly toothed, slightly hairy, on stalks about $\frac{1}{2}$ in. long. Flowers in June, white, $\frac{1}{2}$ in. across, in branched cymes 2-6 in. across. Fruit brilliant red. This species is still very rare.

Culture &c. as above.

V. erosum.—A sturdy Japanese and Chinese shrub 5 ft. or more high, with much-forked branches, and ovate-pointed leaves, 2-4 in. long, with small, linear stipules. Flowers in summer, greenish-white, in small clusters. Fruit red.

Culture &c. as above.

V. furcatum (*V. cordifolium*).—A rare and handsome Japanese shrub, 12-15 ft. high, with large, broad, almost round leaves, which assume brilliant scarlet and reddish-purple hues in autumn, and constitute the chief ornamental value of the plant.

Culture &c. as above.

V. Lantana (*Wayfaring Tree*).—A beautiful British, European and temperate Asiatic tree 12-15 ft. high or more.

Leaves broadly oblong, heart-shaped, 2-4 in. long, serrulate, wrinkled, rich red in autumn, covered with a pale down beneath, also on the young branches. Flowers in May and June, white, $\frac{1}{4}$ in. across, in flat, stoutly rayed cymes. Fruit at first red, afterwards black. There is a rather valueless form, with variegated white and yellow leaves.

Culture &c. as above.

V. lantanoides (*V. alnifolium*).—*Hobble Bush*; *Moosewood*.—A beautiful N. American shrub or small tree, with roundly ovate or heart-shaped leaves, 3-6 in. across, bluntly pointed, closely serrated, beautifully claret-tinted in autumn, with a rusty down on the veins beneath, as well as on the stalks and young branches. Flowers in May, white, the outer ones sterile, an inch or more across, in broad, flat, sessile cymes. Fruit at first coral-red, afterwards dark-purple or black.

Culture and Propagation.—This species does not succeed in all places. It probably requires a moist and somewhat shady position. It is said to grow well grafted on stocks of *V. Lantana*.

V. Lentago (*V. nitidum*).—*Sheep Berry*; *Sweet Viburnum*.—A handsome tree 15-30 ft. high, native of Eastern N. America, with long-stalked, shining, ovate or lance-shaped leaves, tapering rather abruptly to a fine point, and minutely and regularly toothed on the margins. Flowers from May to July, creamy white, all fertile, in a sessile cyme. Fruit bluish-black, edible, sweet, oval, about $\frac{1}{2}$ in. long.

Culture &c. as above.

V. macrocephalum (*V. Fortunei*).—This beautiful Chinese shrub is said to reach a height of about 20 ft. Leaves bluntly ovate, 2-4 in. long, denticulate, with a roughish down on the under surface. Flowers in June, all large and sterile, 1-1 $\frac{1}{2}$ in. across, pure white, borne on pyramidal trusses.

The variety *Keteleeri* is the wild type, from which the cultivated *V. macrocephalum* has sprung. It is like the sterile plant in habit, but the centre of the flower trusses have small, fertile flowers, the outer ones only being sterile.

Culture &c. as above.

V. molle.—A vigorous shrub 6-12 ft. high, native of the S.E. United States, and closely related to *V. dentatum*.

Leaves broadly oval, obovate or ovate, coarsely crenate or toothed, very downy beneath. Flowers in July, white, in downy cymes. Fruit purple or blue, ovoid, small, but larger than that of *V. dentatum*.

Culture &c. as above.

V. nudum (*American Withe Rod*).—A native of the N. United States, 6–10 ft. high, and closely resembling *V. cassioides*. Leaves thick and glossy, oval, oblong or lance-shaped. Flowers in May and June, white, all fertile, in shortly stalked cymes. Fruit black when ripe, sweet, ovoid, $\frac{1}{4}$ in. long. There is a variety called *Claytoni* but very rarely seen.

Culture &c. as above.

V. odoratissimum (*V. Awafuki*).—A handsome evergreen Chinese shrub, 6–10 ft. high, with elliptic, leathery, shining green leaves 3–6 in. long, entire or somewhat sinuate-toothed. Flowers in May, small and dull white, but very fragrant, in corymbs 2–4 in. high.

This species is only hardy in the southern parts of England and Ireland. In cooler places it requires the shelter of a south wall.

Culture &c. as above.

V. Opulus (*V. edule*; *V. Oxycoccus*).—*Guelder Rose*; *Snowball Tree*; *Cranberry Tree*; *Dog Rowan Tree*; *Marsh or Water Elder &c.*—A handsome shrub 6–15 ft. high, native of the British Islands, Europe, N. and W. Asia, and N. America. Leaves 2–3 in. long, 3-lobed, the young ones downy; lobes unequal, serrated. Flowers in June and July, creamy white, in rounded cymes 2–4 in. across. Fruits red, globose, translucent, $\frac{1}{3}$ in. in diameter, very handsome in autumn.

The variety *sterile* is best known as the *Guelder Rose* or *Snowball Tree*, and is remarkable for having nearly all pure white, sterile flowers, which cannot of course produce the beautiful fruits of the less showy form.

There is a variety called *fructu luteo*, with yellow instead of red berries; *nanum*, a curious dwarf plant, 1–2 ft. high, forming dense, rounded tufts, but does not flower freely. There is also a form (*foliis variegatis*) with white and yellow variegated leaves.

Culture &c. as above.

V. plicatum.—A beautiful Japanese shrub 4–6 ft. high with dark green, oblong-

elliptic or roundish, coarsely serrated, plaited leaves 3–5 in. long, smooth above, downy beneath. Flowers in May and June, pure white, all sterile, in globular heads 3 in. or more across, at the tip of almost every branch, and resembling the *Guelder Rose*. Botanically *V. plicatum* is the sterile form of *V. tomentosum*. When well established *V. plicatum* is perhaps the finest species in cultivation and is very hardy.

Culture &c. as above.

V. prunifolium (*Black Haw*).—A native of the Central and Southern United States 6–15 ft. high. Leaves dark shining green like those of a Plum, finely and sharply serrated, often assuming beautiful red or purple tints in autumn. Flowers in May and June, pure white, succeeded by bluish-black fruits.

Culture &c. as above.

V. pubescens.—A somewhat compact shrub 6 ft. or more high, with roundish, coarsely toothed leaves $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long on purplish, downy stalks. Flowers in June, creamy white, tubular, in flat cymes. Fruits oval, $\frac{1}{2}$ in. long, bluish-black. It is a native of N. America.

Culture &c. as above.

V. Sieboldi (*V. reticulatum*).—A strong sturdy Japanese bush with dark glossy green, obovate leaves 2–5 in. long, strongly veined and coarsely toothed towards the apex. Flowers in early summer, creamy white, all fertile, in flat terminal cymes. Fruit black, about 1 in. long.

Culture &c. as above.

V. Tinus (*Laurustinus*).—An ornamental evergreen 8–10 ft. high, with ovate oblong entire leaves, glandular hairy beneath. Flowers from Christmas to Easter, rosy in bud, white when open, in flat trusses 2–3 in. across. Fruits dark blue, rarely produced. It is a native of the Mediterranean region.

Culture &c. as above. Except in severe winters this species is hardy in most parts of the country, but prefers sunny situations. If cut down by frost new branches are almost sure to spring up again. There are several varieties, including: *Fræbeli*, with pale green leaves and white flowers; *hirtum*, which flowers in autumn and winter and has oval oblong leaves, hairy beneath; *lucidum* flowers in spring, leaves large, shining, smooth. There is a sub-variety of this with varie-

gated leaves; *strictum*, an erect-growing kind, of which there is also a variegated form; *virgatum*, an Italian variety with oblong lance-shaped leaves, hairy beneath, and on the margins. There are others, such as *purpureum*, *pyramidale*, *rotundifolium*, *variabile* &c. more or less distinct.

V. tomentosum.—This is the fertile flowering form of *V. plicatum*, from which it differs in having more hairy, oblong, serrate, roughish leaves, and only the outer flowers large, showy and sterile, those in the centre being smaller and with stamens and pistil.

Culture &c. as above.

SYMPHORICARPUS (*St. Peter's Wort*; *Snowberry Tree*).—A genus containing about 6 species of handsome dwarf deciduous shrubs, with opposite, shortly stalked, ovate, entire or sinuate-toothed leaves. Flowers small in short axillary racemes or spikes. Calyx tube nearly round, limb irregularly 4-5-toothed. Corolla funnel- or bell-shaped, 4-5-lobed. Stamens 4-5. Drupes berry-like, white or red, ovoid or round, fleshy, 4-stoned.

Culture and Propagation.—Snowberries grow well in ordinary garden soil and may be increased by suckers which are freely produced. Seeds may be sown in the open border when ripe in a prepared spot, and the seedlings may be transplanted in mild weather the following spring or autumn. But the plants are hardly worth this trouble. They are scarcely suitable for the flower border or shrubbery but make excellent covert plants. They are very graceful looking, with the green leaves and slender branches swaying gently in the breeze.

S. occidentalis (*Wolf Berry*).—A native of N. America, 3-5 ft. high. Leaves ovate, entire or sinuate-toothed, or lobed on the young shoots, downy beneath. Flowers in summer, white tinged with rose, bearded within. Closely related is *S. Heyeri*, a native of Colorado, with rhomboid prominently veined leaves of firm texture, and pretty rose-coloured flowers.

Culture &c. as above.

S. racemosus (*Common Snow Berry*).—A N. American shrub 4-5 ft. high, with oval entire leaves, glaucous beneath. Flowers from July to September, rosy, in loose spikes at the ends of the branches; corolla bearded inside. Berries white,

almost as large as a Barcelona Nut, persistent during the winter. There is a variety called *pauciflorus* with fewer flowers.

Culture &c. as above.

S. vulgaris (*Coral Berry*; *Indian Currant*; *Common St. Peter's Wort*).—A North American shrub 3-6 ft. high, with blunt elliptic-ovate, glaucous leaves, downy beneath. Flowers from July to September, red and yellow, in small dense clusters in the axils of the leaves; corolla slightly bearded. In winter one of the chief attractions of this shrub is the white berries, which are borne in great abundance and are very conspicuous. There is a pretty variety (*foliis variegatis*), having the leaves beautifully variegated with green and yellow. This species is now known as *S. orbiculatus*.

Culture &c. as above.

ABELIA.—A genus of very ornamental deciduous or evergreen shrubs with stalked opposite leaves, and terminal or axillary clusters of flowers. Calyx-lobes leafy or linear. Corolla funnel-shaped, 5-lobed. Stamens 4, equal; or 2 long and 2 short. Ovary 3-celled. Fruit a leathery, 1-seeded berry.

Culture and Propagation.—Abelias are hardy only in the southern parts of England and Ireland, although in more northern parts they may survive hard winters with a little protection against sunny south walls. They thrive in a mixture of sandy peat and loam, and may be increased by layers; or by cuttings in sandy soil in summer, under glass, or in a cold frame.

A. chinensis (*A. rupestris*).—A deciduous hairy Chinese shrub about 5 ft. high with small oblong leaves. Flowers in autumn, small, pink, in pairs at the tips of the branches, sweet-scented; sepals leafy, reddish-tinged. The variety *grandiflora* is a garden seedling with rosy white flowers.

Culture &c. as above.

A. floribunda.—A free-flowering, evergreen Mexican species about 3 ft. high, with ovate oblong leaves. Flowers in March, rose-purple, 2 in. long, in drooping axillary clusters.

Culture &c. as above. This is rather tender in northern parts of the kingdom and is best grown against a south wall in such localities.

A. serrata.—A fine Chinese evergreen shrub about 3 ft. high, with serrated leaves. Flowers in March, pale red, sweet-scented, large.

Culture &c. as above.

A. spathulata.—A free-flowering Japanese evergreen shrub 2-3 ft. high. Leaves about 2 in. long, elliptic lance-shaped, bluntly pointed, sinuate-toothed, smooth above, downy beneath, edged with purple. Flowers in April, about 1 in. long, in pairs, white with yellow blotches in the throat of the corolla.

Culture &c. as above.

A. triflora.—A pretty Himalayan shrub 2-3 ft. high, with ovate lance-shaped pointed leaves 2-3 in. long. Flowers in summer, $\frac{1}{2}$ in. across, in threes in large clusters in the axils of the leaves and at the ends of branches; they are pale yellow inside with a pink or purple tube, and white, oblong, wavy, reflexed petals.

Culture &c. as above. When well grown this is a very striking plant when covered with masses of its sweet-scented flowers.

A. uniflora.—A handsome Chinese species, with broadly lance-shaped thick deep green shining leaves, somewhat like those of the common Myrtle, and large pink and white bell-shaped flowers drooping from the branches in August. Calyx lobes leafy and tinged with brown.

Culture &c. as above.

LINNÆA.—A genus with only one species, native of Britain and the N. Hemisphere.

L. borealis.—A pretty trailing subshrubby creeping evergreen with roundish or ovate, crenate, slightly hairy leaves. Flowers in June and July, flesh-coloured, twin, drooping, fragrant, on axillary peduncles. Corolla bell-shaped, 5-parted, with a cylindrical tube. Stamens 4, two short and two long.

Culture and Propagation.—This is an excellent plant for moist parts of the rockery or in cool borders. It thrives in peaty soil, and may be increased by division in early autumn or spring.

LONICERA (HONEYSUCKLE).—This genus contains about 80 species of erect, trailing, or climbing shrubs, with opposite, simple, entire or lobed, deciduous or evergreen leaves. Flowers often fragrant, cymose, axillary or capitate, sometimes

adhering by the ovary in pairs. Calyx-limb of 5 often unequal teeth. Corolla tubular or bell-shaped, gibbous in some species at the base, limb oblique or 2-lipped. Stamens 5. Fruit a fleshy, 2-3-celled berry.

Culture and Propagation.—Loniceras are charming plants for covering walls, arbours, trellises &c. They love sunshine, and a light rich soil, and should therefore not be planted, as is often seen, in deep shade at the base of a shady tree, where the roots have to struggle for existence on the scanty remnants left by those of the tree.

In some of the deciduous species a little judicious pruning is occasionally required. The old wood should be thinned out to induce new growths to develop, thus giving a chance of greater profusion of flower, and also keeping the plants well furnished with leaf-bearing shoots.

Loniceras root readily in autumn from cuttings of the ripened young shoots placed in sandy soil under a handlight or in a cold frame. They may also be obtained by layers or from seeds. The latter may be sown when ripe or in spring in cold frames, afterwards pricking the seedlings out when large enough into light rich soil.

L. Alberti.—A distinct and pretty smooth branching shrub 2-3 ft. high, native of Eastern Turkestan, with slender dependent branches. The rather blunt linear oblong leaves about an inch long resemble those of *Lycium* (see p. 691), and have a glaucous hue. The sweet-scented rosy-lilac flowers, with an almost regular 5-parted corolla, appear in June in pairs in the axils of the leaves.

Culture &c. as above.

L. alpigena.—This species grows about 6 ft. high and is a native of the mountains of Central and S. Europe, and the Himalayas. The erect stems are furnished with oval lance-shaped acute, shortly stalked leaves, the margins of which are slightly toothed. The flowers are of a somewhat dull red, and appear in April and May. There is a dwarf variety (*nana*) about a foot high, which makes a useful rock plant, and is remarkable for its shining crimson Cherry-like fruits in August and September.

L. webbiana, from the Himalayas, is closely related to this species. It has large oblong-elliptic leaves, abruptly

pointed, and 2-lipped yellowish-green flowers tinged with purple outside.

Culture &c. as above.

L. angustifolia.—A rather handsome deciduous shrub 4–6 ft. high, native of the Himalayas. It has slender branches and narrow lance-shaped leaves rather more than an inch long, and fringed with hairs on the margins. The small tubular pale yellow flowers appear in April and May, and are borne in pairs at the end of a slender drooping stalk issuing from the leaf axil.

Culture &c. as above.

L. bella.—A very handsome bush Honeysuckle about 4–6 ft. high, said to be a hybrid between the Japanese *L. Morrowi* and *L. tatarica*. It retains its leaves until quite late in autumn, and in April and May produces its soft yellow or rose-tinted flowers in great abundance. These are afterwards followed, about July, with showy masses of scarlet fruits resembling Red Currants. The variety *albida* with whitish blossoms is an excellent plant.

Culture &c. as above.

L. Caprifolium.—A native of Central and S. Europe and W. Asia, but now naturalised in the copses of Cambridge and Oxford. Upper leaves united by very broad bases, oblong or triangular, glaucous beneath; lower ones stalked, broadly ovate or oblong. Flowers in May and June, yellowish, with a purplish tube 2 in. long, highly fragrant, borne in capitate whorls. Berries globose, scarlet.

Culture &c. as above.

L. confusa (*L. halleana*).—A slender twining Japanese species with ovate, deep green leaves, sometimes ruddy tinted. Flowers in summer, pure white at first, changing to yellow, in pairs from the axils of the leaves at the tips of the young shoots. This plant is now regarded as a variety of *L. japonica*.

Culture &c. as above.

L. etrusca.—A deciduous European climber with obovate, blunt, downy leaves, lower ones shortly stalked, upper ones united at the base, acute. Flowers in May and June, purple outside, yellow within, sweet-scented, in verticillate heads at the ends of the branches. *L. semperflorens* is probably a variety of this.

Culture &c. as above. Requires to be grown in warm sheltered spots.

L. flava (*L. Fraseri*).—A pretty N. American climber, with smooth, thickish, obovate or oval, very pale green leaves, glaucous on both sides, the 2–4 upper pairs united into round cup-like disks. Flowers in June, bright yellow; tube of the corolla somewhat gibbous.

Culture &c. as above.

L. flavescens.—This shrubby Honeysuckle is also known in some gardens as *L. webbiana*, the true plant of which, named by Wallich, is probably not in cultivation, or very rarely seen. The plant here described is said to be a native of British Columbia. It has lance-shaped tapering leaves, ovate acute bracts, and united bracteoles, which conceal the base of the almost regular corolla. The flowers appear in early summer and vary in colour from sulphur-yellow to citron-yellow, and are slightly covered with glandular hairs.

Culture &c. as above.

L. flexuosa (*L. brachypoda*).—A deciduous Japanese purple-stemmed climber, with smooth, ovate-oblong acute leaves on short stalks, and ruddy tinged. Flowers in June and July, yellow or purplish, nearly sessile, sweet-scented. This is now regarded as a variety of *L. japonica*.

Culture &c. as above.

L. fragrantissima.—A beautiful Chinese climber, with oblong ovate acute leaves rounded at the base, nearly smooth and almost evergreen, except in severe winters, when they drop. Flowers in January and February, creamy-white or pale yellow, sweet-scented, nearly 1 in. across, tube short, mouth expanded, appearing before the leaves are developed.

Culture &c. as above.

L. grata.—A vigorous climber from the New England States, with broad, glaucous, almost evergreen leaves. Flowers in May in clusters, whitish with a purple tube fading to yellow, sweet-scented. This plant is now regarded as a form of *L. Caprifolium*.

Culture &c. as above.

L. hispida (*L. bracteata*).—A Himalayan Honeysuckle 2–3 ft. high, with hairy branches and shortly stalked oblong acute ciliate leaves, 1½–2 in. long, smooth on both surfaces. The drooping greenish-white flowers about 1 in. long appear in early summer, in pairs, having large ovate bracts, and are followed in autumn by purple-coloured berries.

Culture &c. as above.

L. implexa (*L. balearica*).—A native of the Balearic Isles, Sicily &c., with roundish evergreen leaves. The flowers are purple outside and yellow within, and assume a deeper yellow tinge with age.

Culture &c. as above. This is rather too tender for northern parts of the kingdom, and even in good localities it cannot be regarded as a vigorous grower.

L. japonica (*L. chinensis*).—A slender hairy Japanese and Chinese climber with stalked, ovate-acute, hairy leaves, pale beneath. Flowers from July to September, about 1 in. long, red, hairy outside, white within, sweet-scented, in pairs at the tips of the young shoots. The variety *aureo-reticulata* is an elegant climber with more or less elliptic leaves beautifully netted with golden yellow.

Culture &c. as above.

L. Kesselringi.—A dwarf and much-branched shrub, native of Kamtschatka. Leaves more or less elliptic lance-shaped, green above, grey beneath. The flowers appear in pairs in the leaf axils, and are red outside, red and white inside, with a bearded throat.

Culture &c. as above.

L. Korolkowi (*L. floribunda*).—A native of Turkestan with small grey-green ovate leaves and numerous pale rose-coloured blossoms borne on short twigs. There seems to be another plant under this name having yellowish-white flowers and orange-red fruits.

Culture &c. as above.

L. Maacki.—A rather pretty Manchurian shrub with oblong acute leaves, and almost stalkless white flowers produced in the leaf axils in early summer. The corolla is less than an inch in length, and is 2-lipped, the lower lip being shortly 4-lobed.

Culture &c. as above.

L. Morrowi.—A handsome Japanese Honeysuckle resembling *L. ruprechtiana*, from which it differs in having smaller and paler green leaves. It makes a fine bush, and is very ornamental when covered with its showy red berries.

Culture &c. as above.

L. Periclymenum (*Woodbine* or *Honeysuckle*).—A native of British hedges and copses, with climbing twisted branches. Leaves deciduous, 1-3 in. long, ovate or oblong, glaucous beneath, lower ones shortly stalked, upper ones

sessile. Flowers from June to September, 1-1½ in. across, glandular downy, dirty red outside, yellow inside. Berries round, crimson. The variety *serotina*, known as the 'Late Dutch Honeysuckle,' produces its deeper red flowers in autumn. *Belgica*, known simply as the 'Dutch Honeysuckle,' is a stronger-growing plant than the type, and has flowers red outside, yellow within. *Quercifolia*, the 'Oak-leaved Honeysuckle,' has leaves sinuated like those of an Oak.

Culture &c. as above.

L. quinquelocularis (*L. diversifolia*). A Himalayan species with elliptic or ovate leaves, downy beneath, and ciliate on the margins. The yellowish flowers appear in summer and are succeeded by white berries.

Culture &c. as above.

L. ruprechtiana.—A distinct and handsome Honeysuckle, native of Manchuria. The leaves are pale green, somewhat downy beneath. The clusters of pale yellow flowers tinged with rose are borne in great abundance in early summer, and are in due course succeeded by bright scarlet translucent berries on gracefully arching stems. There are several variations of this species, the chief difference being the depth of the colouring in the flowers.

Culture &c. as above.

L. sempervirens (*Trumpet Honeysuckle*).—A beautiful North American evergreen climber with obovate or ovate smooth leaves, glaucous beneath; upper ones united at the base. Flowers in spring and summer, about 1 in. long, beautiful scarlet outside, yellow within. There is a variety called *minor* with smaller blossoms.

Unfortunately this species is not perfectly hardy in all parts of the country; hence its presence in cool greenhouses. It grows well in southern parts, but in other places requires the protection of a sunny south wall,

Culture &c. as above.

L. Standishi.—This Chinese climber is closely related to *L. fragrantissima*. It has ovate-oblong or ovate-lanceolate leaves, fringed at the edges, and with hairy flower stalks. Flowers early in the year, white tinted with purple, sweet-scented. This is often confused with *L. fragrantissima*, but it is a purely deci-

duous species, and does not open its blossoms so soon.

Culture &c. as above.

L. tatarica.—A deciduous twiner, native of Tartary. Leaves heart-shaped ovate, somewhat acute. Flowers in April and May, in pairs, rosy; corolla tube rather gibbous at the base. Fruits black, nearly round when young, but at length united at the base. There is a variety *albiflora* with white flowers; *micrantha* with small pink flowers changing to yellow, and succeeded by small red berries; and *rubriflora* with purple-red flowers.

Culture &c. as above. This is one of the hardiest and best flowering of Honeysuckles, but it has a tendency to lose its leaves rather too early towards the end of summer.

L. Xylosteum (*Xylosteum dumetorum*).

Fly Honeysuckle.—An erect deciduous shrub native of Europe and N. Asia, but naturalised in parts of the eastern and southern counties of England. Leaves 2-3 in. long, shortly stalked, ovate or obovate. Flowers in May and June, $\frac{1}{2}$ in. across, yellow, downy, sessile. Berries small, crimson. The variety *leucocarpum* has white berries; *melanocarpum*, black; and *xanthocarpum*, yellow.

Culture &c. as above.

LEYCESTERIA (FLOWERING NUT-

MEG).—This genus contains only one species:—

L. formosa.—A handsome deciduous shrub 4-6 ft. high, native of the temperate Himalayas, with hollow stems, and rather large, ovate-lance-shaped, pointed, stalked, smooth, entire leaves. Flowers in summer, small, white or purplish, in short leafy drooping racemes, at the ends of the branches. Calyx-lobes linear, unequal. Corolla funnel-shaped, 5-lobed, gibbous above the base. Bracts large, leafy, purplish, downy, generally 6 under each whorl of flowers. Berries dull purple, many-seeded. There is a form with variegated foliage.

Culture and Propagation.—This species thrives in good garden soil, and in mild districts will retain its foliage. It may be increased by cuttings of the young shoots in spring, or by older ones in autumn under a handlight or cold frame. Seeds may also be sown in spring or in autumn as soon as ripe in cold frames. The seedlings when large enough may be pricked out into light

rich soil in warm and sheltered parts of the garden. Pheasants are very fond of the berries.

DIERVILLA (WEIGELA).—BUSH HONEYSUCKLE.—A genus of handsome flowering shrubs, with opposite sessile or stalked leaves, and showy flowers in axillary and terminal clusters. Calyx-tube very slender, produced above the ovary. Corolla funnel- or bell-shaped, nearly regular. Stamens 5. Style simple, slender, protruding, with a capitate stigma.

Culture and Propagation.—Diervillas are among the best and showiest of ornamental flowering shrubs, and fortunately are easily grown in any good soil in rather moist and partially shady situations. They are easily increased by cuttings in spring or autumn inserted in sandy soil under a handlight, or from the freely produced suckers. In groups on grass or in shrubberies Diervillas are always effective when in leaf and blossom, although owing to their deciduous nature they are in a leafless state for a short period of the year. During the winter months an opportunity is given to cut out any old or decaying branches, or others which may be crowding the centre too much so as to prevent the admission of sunshine and free circulation of air. A good mulching of well-decomposed manure in autumn or winter will be of great assistance in keeping the plants in a vigorous, healthy, and free-flowering condition.

There seems to be a good deal of confusion in regard to the naming of the various species. In the Kew herbarium there are specimens labelled *D. grandiflora*, *D. florida*, *D. japonica*, '*D. versicolor*', *D. floribunda*, and *D. hortensis*, all more or less alike, the chief difference being in the size of the leaves. The kind labelled *grandiflora* has larger and wider leaves than the others, but to make the confusion worse, this plant has now been referred to a hitherto almost unheard-of species, *D. corænsis*, by the 'Kew Index.'

D. grandiflora (*D. amabilis*).—A beautiful Japanese shrub about 8 ft. high, with leaves strongly veined on the under side. Flowers in early summer, pink. There are several varieties, among which may be mentioned: *Abel Carrière*, *Isolineæ*, *striata*, *Van Houttei*, *Graenowegenei* &c., but some of these and

others mentioned in catalogues have become intermixed by the crossing of *D. grandiflora* and *D. rosea*. The variety called *præcox* has deep rosy flowers with a carmine and yellow throat, and is a very valuable shrub owing to the fact that it comes into bloom early in May, nearly a month before the other forms.

Culture &c. as above.

D. hortensis.—A Japanese shrub 4–5 ft. high, with stalked, ovate, pointed, softly hairy leaves, having crenate or crenate-serrulate edges. Flowers red or white, slightly hairy outside and borne in great profusion in May and June. The variety *nivea* has pure white flowers and is a remarkably handsome bush.

Culture &c. as above.

D. Lonicera (*D. canadensis*).—A N. American shrub 3–4 ft. high, with creeping roots, and short-stalked, ovate-pointed, serrate, smooth leaves, bright tinted in autumn. Flowers in summer, yellow.

Culture &c. as above.

D. middendorffiana.—A Siberian shrub with nearly sessile, ovate-lance-shaped, finely netted leaves, 2½–3½ in. long, sharply serrate on the margins and hairy on the nerves. Flowers in terminal panicles, yellowish-white, the lower petal dotted with pink.

Culture &c. as above.

D. rosea.—A Chinese shrub about 6 ft. high, with ovate lance-shaped, serrulate leaves. Flowers in spring, rose or white, numerous. There are many fine varieties, including *nana*, *nana aurea* (with young leaves golden-yellow), *Stelzneri*, *Lavallei*, *Looymanei* &c. It may be remarked that all the forms of *D. grandiflora*, *D. amabilis*, and *D. rosea* are now placed under one specific name, to wit, *D. florida*, according to the 'Kew Handlist.'

Culture &c. as above.

D. sessilifolia.—A handsome hardy shrub 3–5 ft. high, native of the mountains of N. Carolina. The ovate tapering acute leaves with serrate margins are about 3 in. long, and sit opposite each other on the stems without stalks. The yellow flowers, although individually little more than ½ in. across, are borne in great abundance in June on short-stalked cymes, and are decidedly attractive.

Culture &c. as above. Being a comparatively recent introduction, but little can be said as to the behaviour of this distinct yellow-flowered species. It seems however to be hardy in the milder parts of the kingdom, and will doubtless succeed under the same conditions as the other species. There is a form of it called *splendens*.

LIX. RUBIACEÆ—Woodruff Order

A large order with about 340 genera and over 4,000 species of erect, trailing, or climbing trees, shrubs, or herbs, very few of which are hardy. Leaves simple, opposite or whorled, entire, serrated, toothed, or pinnatifid-lobed. Stipules persistent or deciduous, free or adnate to the leaf stalk. Flowers usually hermaphrodite and regular. Calyx-tube adnate to the ovary; limb superior, somewhat cup-like or tubular, entire, toothed or lobed. Corolla gamopetalous, funnel-shaped, salver-shaped, bell-shaped, or rotate, smooth or hairy within. Stamens as many as the corolla lobes, rarely fewer, inserted in the tube. Fruit a capsule, berry, or drupe, 2–10 seeded.

The *Bouvardia*, *Gardenia*, *Coffee* and *Cinchona* belong to this order, but cannot be regarded as hardy plants in the British Islands.

CEPHALANTHUS.—A small genus of erect-growing shrubs or small trees with round or bluntly 4-angled stems. Leaves opposite or 3–4 in a whorl, shortly stalked, oblong or ovate lance-shaped, with short stipules between the stalks. Flowers in round compact heads. Calyx

unequally 4–5-toothed, or 4-lobed. Corolla tubular or funnel-shaped, quite smooth, or hairy in the throat, and having 4 erect or spreading lobes. Stamens 4.

C. occidentalis.—A handsome deciduous shrub 5–6 ft. high, native of North America. The ovate tapering leaves are

opposite or 3 in a whorl, and the whitish-yellow flowers appear about July in roundish heads at the ends of the shoots.

Culture and Propagation.—This little-known plant may be grown in the same soil and situation as the hardy Azaleas and Rhododendrons. It likes a moist sandy peat, but will also flourish in ordinary good garden soil, which although moist must also be well drained. The easiest way to increase the plant is by layering the ripened branches in autumn and detaching them the following spring or autumn when well rooted.

HOUSTONIA.—A genus with about 20 species of perennial herbs, having broad or narrow opposite leaves, and dimorphic flowers arranged in the axils of the leaves or in forked cymes. Calyx with 4 lobes, sometimes alternating with teeth, erect or recurved. Corolla funnel- or salver-shaped, 4-lobed. Stamens 4. Ovary 2-celled.

Culture and Propagation.—Most Houstonias flower nearly all the year round, and are excellent little plants for the rock garden. They like fine sandy and peaty soil with plenty of moisture, and are increased by division in early autumn, or by seeds in spring sown in cold frames or gentle heat about March, or in the open border about April and May. Chiefly natives of N.W. America.

H. cærulea (*Bluets*).—A charming little evergreen perennial 2-4 in. high, native of Virginia. Leaves ovate-lance-shaped, the lower ones spoon-shaped, slightly hairy, and forming low masses on the ground. Flowers from about May onwards, beautiful light blue, sometimes white as in the pretty variety *alba*. Corolla salver-shaped, $\frac{1}{2}$ in. across.

Culture &c. as above.

H. longifolia.—A species about 6 in. high, with linear oblong upper leaves, and broadly ovate, entire, or twice or thrice toothed lower ones tapering at the base and ciliated. Flowers in August, pale lilac or lavender.

Culture &c. as above.

H. serpyllifolia.—A species about 3 in. high, with rather hairy spoon-shaped leaves, like those of Thyme. Flowers during summer, white.

Culture &c. as above.

ASPERULA (*WOODRUFF*).—A genus of about 50 species of pretty herbaceous

plants with more or less 4-angled stems, and opposite leaves with one, two, or three leaf-like stipules on each side, making the whole look like a whorl of leaves. Flowers terminal and axillary in fascicles. Calyx-limb wanting. Corolla funnel- or bell-shaped, 4-lobed. Stamens 4 inserted on the tube or throat of the corolla.

Culture and Propagation.—The Woodruffs are pretty plants for the margins of shrubberies, narrow borders, or parts of the rockery, and thrive in any garden soil. They are readily increased by division of the roots in spring or summer after flowering. Seeds may also be sown as soon as ripe in prepared beds of good soil; or they may be sown in the open border in spring, and transplanted when large enough to handle easily, or merely thinned out if sown where the plants are to bloom.

A. cynanchica.—A smooth British perennial 9-12 in. high. Leaves 4 in a whorl, oblong lance-shaped. Flowers in summer, white or blue, elegantly marked with red lines; sometimes pure white.

Culture &c. as above.

A. longiflora.—A smooth weak-stemmed Hungarian species about 6 in. high. Leaves 4 in a whorl, linear-obovate. Flowers in summer, whitish, tinged with yellow inside, red outside.

Culture &c. as above.

A. montana.—A Hungarian species 6-8 in. high. Leaves linear, lower ones 6 in a whorl, passing to 4 and 2 upwards. Flowers in June and July, pink.

Culture &c. as above.

A. odorata (*Sweet Woodruff*).—A charming British plant 6-12 in. high, with square stems, and lanceolate, minutely toothed leaves 8 in a whorl. Flowers in May and June, pure white, numerous. When dried the plant has a delicious hay-like scent. It imparts an agreeable perfume to clothes and preserves them from insects.

Culture &c. as above.

A. orientalis (*A. azurea setosa*).—A beautiful Caucasian annual about 1 ft. high, with lance-shaped, bristly leaves, about 8 in a whorl. Flowers profusely in summer, sky-blue in colour, very fragrant.

Culture &c. as above.

CRUCIANELLA (*Crosswort*).—A genus containing about 26 species of annual or perennial hairy herbs, with 4 or more linear lance-shaped leaves in a whorl. Flowers in spikes or fascicles; corolla funnel-shaped, with a long slender tube.

C. stylosa.—A pretty dwarf procumbent plant, 9-12 in. high, native of the Caucasus and Persia. Leaves 8-9 in a whorl. Flowers in summer, pale rose, small, freely produced in dense terminal heads, style much protruding beyond the mouth of the corolla. There is a scarlet-flowered form called *coccinea* and also one called *purpurea* with purple blossoms.

Culture and Propagation.—This plant is suitable for borders, bare banks, or rockeries, in sandy or chalky soil. It makes large masses or tufts and requires to be either divided or cut back to be kept within bounds. It is easily increased by division in early autumn or spring, and by means of seed sown in cold frames as soon as ripe, or in the open border about April; or in gentle heat about March.

MITCHELLA.—A genus with a few species of smooth or downy creeping herbs, with opposite, shortly-stalked, ovate rounded leaves, and white fragrant flowers. Calyx tube ovoid; limb 3-6-toothed. Corolla funnel-shaped, bearded in the throat; limb 3-6-lobed, recurved, valvate. Fruit scarlet.

M. repens.—A pretty little North American plant with small reddish leaves often marked with whitish lines. Flowers in summer, white, tinged with purple, fragrant, usually two on each stem.

Culture and Propagation.—A useful plant for rockwork in ordinary soil. It may be increased by division in early autumn or spring; or seeds may be sown in cold frames when ripe, or in gentle heat in March, afterwards transferring the seedlings to the open about the end of May.

NERTERA.—A small genus of slender smooth or slightly hairy creeping herbs with small, opposite, sessile or stalked, more or less ovate lance-shaped leaves. Flowers inconspicuous, sessile axillary, hermaphrodite, or one-sexed by abortion. Calyx tube ovoid 4-5-toothed. Corolla tubular or funnel-shaped with a smooth throat, and 4 sub-erect lobes. Stamens 4, protruding. Ovary 2-celled; style 2-branched. Fruit a fleshy red ovoid or globose 2-stoned drupe.

N. depressa (*Bead Plant*).—A charming New Zealand plant forming dense tufts or masses of small ovate rather fleshy bright green leaves. Flowers minute, greenish or pinkish, succeeded by great numbers of juicy bright orange-red roundish berries about half the size of Peas.

Culture and Propagation.—This interesting little plant has been called the Flowering or Fruiting Duckweed, but it has no affinity at all with the true Duckweed, which is nearer the Arrowheads (p. 806) and Flowering Rushes (p. 806). It prefers light sandy loam and a little leaf mould, and makes a bright show in the rock garden if it can be grown in a cool place facing north. It must have plenty of light without strong sunshine, and also an abundance of water during the summer months. Grown in shallow pots or pans under similar conditions in cold frames, the plants may be used in a variety of ways, and are very effective in cold greenhouses. They may be increased by dividing the tufts in early spring and placing the pieces in small pots in light soil plunged in a little heat until established. Afterwards they should be removed to cooler quarters and hardened off as much as possible. Seeds may also be sown as soon as ripe in a cool damp shaded frame, afterwards pricking the tiny seedlings out into pans of finely sifted soil.

LX. VALERIANÆ—Valerian Order

An order comprising 9 genera and about 300 species of annual or perennial herbs, or undershrubs, with opposite entire or pinnatifid leaves and small flowers in forked cymes. Flowers hermaphrodite or sometimes dicecious by abortion. Calyx superior, limb lobed or feathery. Corolla funnel-shaped, tube often spurred at the base; lobes 3-5, unequal. Stamens 1-5, often protruding. Fruit dry, indehiscent.

VALERIANA.—A genus of perennial herbs or undershrubs, the lower leaves

of which are entire or toothed, the upper ones pinnately divided, or twice or thrice

pinnately cut. Flowers white or pink, in cymes, spikes or loose corymbs or panicles. Calyx cut into 5-15 hair-like divisions. Corolla 5-lobed, slightly gibbous at the base. Stamens 3, rarely 1-2 by abortion.

Culture and Propagation.—Although there are about 150 species of Valerian comparatively few are of any garden value. They all flourish in ordinary good and well-drained garden soil, but prefer somewhat chalky surroundings. They are useful for the rougher parts of the garden, and may be planted on old ruins, rockeries, banks &c. in the same way as the species of *Centranthus* mentioned below. Propagation is effected easily by seeds sown as soon as ripe in cold frames; in gentle heat in March; and in the open border in April and May. In the two first cases the seedlings may be transplanted about the end of May. Very often seedlings from self-sown seeds spring up spontaneously, and thus reproduce the plant naturally. Division of the roots may also be adopted to increase the plants in early autumn or in spring.

V. montana.—An elegant perennial 4-6 in. high, native of the Alps. It forms bold masses in the rockery or border, and has entire leaves, the lower ones being oblong spoon-shaped, the upper ones lance-shaped. The beautiful soft rosy pink flowers appear from April to June, and are borne in regular corymbs.

Culture &c. as above.

V. officinalis (*Cat's Valerian; All Heal*).—This perennial is a native of the British Islands, and is found wild near the banks of streams, and in damp pastures. It grows about 3 ft. high, and the glaucous leaves are all pinnately cut into entire or serrate lobes. Flowers from June to August, pale pink or white, in 3-forked corymbs.

Culture &c. as above. Although not so handsome as other Valerians, this species is useful for damp shady parts of the garden. It emits a peculiar odour which has a decided attraction for cats. These garden pests roll over and over the plants and enjoy themselves but spoil the plants. The Cat Valerian therefore should not be planted near choicer perennials, as the latter are sure to suffer from the attention of the cats.

V. Phu.—A rather strong-smelling Caucasian Valerian with fistular stems 2-4 ft.

high and glaucous leaves, the lower ones of which are oval, oblong, entire or toothed, the upper ones being pinnately cut. Flowers white, from June to August. The variegated form with golden leaves in spring is very pretty.

Culture &c. as above. This species is also a favourite with cats.

Other Valerians sometimes met with are *V. pyrenaica* from the Pyrenees. It is a rather coarse-growing perennial 2-4 ft. high, and has large heart-shaped deeply toothed leaves often 1 ft. across, and pale pink flowers like those of the Cat Valerian in July and August; and *V. angustifolia*, a glaucous alpine plant about 1½-2 ft. high with linear lance-shaped leaves, all entire and nearly perfoliate. Flowers from May to July, bright rose, but occasionally white. They require similar treatment to the other Valerians.

CENTRANTHUS (*Spur Valerian*).

A genus of 10 species of ornamental herbaceous annuals or perennials with entire or pinnate leaves. Flowers in corymbose or panicled cymes at the ends of the shoots. Calyx-limb feathery. Corolla tube slender, flattened lengthways, divided and spurred at the base. Stamens usually 1. Fruit membranous.

Culture and Propagation.—These plants grow well in ordinary garden soil, and are very handsome in the flower border, on old walls, or rockeries. The perennial kinds may be increased by dividing the roots in early autumn or in spring; by cuttings of the young growths or side shoots in spring or autumn under handlights; or by seeds sown as soon as ripe in cold frames, afterwards pricking the seedlings off, and growing under glass until about the end of May following when they may be transferred to the open air. Seeds may also be sown in gentle heat in March, or in the open border in April and May, but the best plants as a rule are from seeds sown in autumn. The seed of annuals should be sown about March in gentle heat so as to have the plants ready for the border at the end of May.

C. macrosiphon.—A showy, compact-growing Spanish annual 1½-2 ft. high, with fleshy stems and smooth, shining, broadly oval and coarsely toothed glaucous leaves, the lower ones stalked and jagged-edged, upper ones sessile.

Flowers in July, rosy-carmine, larger and brighter than those of *C. ruber*. There is a white-flowered variety, and also a strain called *nana* remarkable for its dwarf compact habit. It forms dense tufts, about 9–12 in. high, the plants being literally covered with blossom.

Culture &c. as above.

C. ruber (*Red Valerian; Pretty Betsy*).—A beautiful and well-known perennial 2–3 ft. high, native of Europe, N. Africa, W. Asia, and naturalised in the British Islands. Leaves ovate or lance-shaped, 2–4 in. long, the lower ones stalked, upper sessile, sometimes toothed at the base. Flowers from June to September, red or white, in dense corymbose panicles. Spur slender.

Culture &c. as above.

FEDIA.—A genus closely allied to the preceding containing only the one species here described:—

F. Cornucopiae.—A pretty glaucous annual native of S. Europe and N. Africa, with purplish stems about 6 in. high, and ovate-oblong toothed leaves; lower ones stalked, upper sessile. Flowers in July, red, lilac-rose, or carmine, in corymbose fascicles with hollow stalks. Calyx 2–4-toothed. Corolla 2-lipped with an elongated tube; upper lip 2-lobed, lower one 3-lobed.

Culture and Propagation.—This species is easily grown in ordinary soil and may be used as a bordering or in the lower parts of the rockery. Being an annual it may be readily raised from seeds sown in the open border in April, afterwards thinning the seedlings out.

LXI. DIPSACEÆ—Teasel Order

An order containing 5 genera and about 125 species of biennial or perennial herbs, with opposite rarely verticillate, entire, toothed, or lobed leaves, no stipules, and flowers in heads surrounded by an involucre. Calyx-limb superior, cup-shaped, entire, lobed or ciliated with five or more rigid bristles. Corolla funnel-shaped or cylindrical, often curved; lobes 4–5, blunt. Stamens 2 or 4, inserted on the corolla tube, often protruding. Fruit indehiscent, covered by the hardened involucrel.

MORINA.—A genus containing about 8 species of smooth or softly downy, perennial, Thistle-like herbs, with oblong, sinuate, spiny-toothed, rarely entire leaves, and flowers crowded in whorls in the axils of the bracts or floral leaves. Corolla long, tubular, gaping. Stamens 4 (2 long, 2 short).

Culture and Propagation.—Morinas thrive in rich sandy loam, and require a little shade and shelter. The roots may be divided to increase the plants as soon as flowering is completely over, and new roots will thus have a chance to develop before the winter frosts set in.

Unless division is performed in early autumn it will be safer to defer the operation until spring. Seeds may be sown also when ripe in rich sandy loam in a cold frame. When the young plants are large enough to handle they may be pricked out into pots, and it is often safer to grow them on thus until the second year, before transferring to the open ground. They are effective plants in the border or rockery, and are perfectly hardy in the milder parts of

the country. In the northern parts, however, they may require the protection of a little dry litter in severe winters.

M. betonicoides.—A beautiful herbaceous perennial 12–18 in. high, native of the Sikkim Himalayas. It has linear lance-shaped Thistle-like leaves with spiny teeth or hairs on the margins, and during the summer months bears heads of bright rosy-purple flowers with a crimson spot at the base of the three lower lobes of the curved funnel-shaped corolla.

Culture &c. as above.

M. coulteriana.—A pretty species 6–18 in. high, native of the Western Himalayas, with narrow, spiny-edged leaves. Flowers in summer, pale yellow, in terminal heads, bracts united into a broad cup, with rigid spines.

Culture &c. as above.

M. longifolia.—A distinct and handsome Himalayan perennial about 2 ft. high or more. Leaves Thistle-like, about 1 ft long, less than 2 in. wide, pinnatifid, with wavy and rather spiny-toothed margins.

Flowers from June to September, white in bud, changing to delicate pink and crimson, in crowded whorls in the axils of the upper leaves or spiny bracts.

Culture &c. as above.

DIPSACUS (TEASEL).—A genus of erect hairy or prickly biennial herbs, with opposite leaves, usually connate at the base, and toothed or jagged at the margins. Flower heads terminal, oblong-ovoid or roundish. Calyx limb superior, cup-shaped, entire lobed, or ciliate. Corolla funnel-shaped or cylindrical, often curved; lobes 4-5, obtuse. Stamens 4.

Culture and Propagation.—The Teasels are best suited for wild parts of the garden, old banks, hedgerows &c. in any soil. Seeds may be sown in such places when ripe, or in spring, and the plants left to look after themselves. They are picturesque in appearance owing chiefly to their large, more or less conical and pitted flower heads, but are hardly choice enough for the herbaceous border.

D. Fullonum (*Fuller's Teasel*).—A prickly-stemmed plant 4-6 ft. high, with oblong lance-shaped, serrate leaves united at the base. Flowers in summer, whitish, with pale purple anthers, in ovoid heads; bracts spreading.

Culture &c. as above.

D. laciniatus.—A bold, prickly-stemmed plant 8-10 ft. high, native of Europe and N. Asia. Leaves united at the base into a cup which holds water when it rains, in the same way as the leaves of the Cup Plant (*Silphium perfoliatum*), sinuately jagged, lobes sinuately toothed, downy beneath. Flowers in July, whitish, with red anthers in ovoid heads. Bracts of involucre slightly erect, stiffish.

Culture &c. as above.

D. sylvestris (*Common Teasel*).—A British and European plant 6 ft. high, with prickly stems and ovate lance-shaped, pointed toothed leaves, united at the base. Flowers in July, pale lilac, in ovoid-oblong heads. Bracts of involucre weak; inflexed.

Culture &c. as above.

CEPHALARIA.—A genus of annual or perennial herbs, closely allied to *Dipsacus*. Leaves toothed or pinnatifid. Flower heads terminal, globose.

Culture and Propagation.—These

plants are scarcely suitable for the flower garden proper, but are appropriate in wild spots and will flourish in any soil. They may be easily increased by division in early autumn or spring; or seeds may be sown as soon as ripe, afterwards transplanting the seedlings to flower the following season.

C. alpina.—A tall-growing perennial native of the Alps, with furrowed stems 6-8 ft. high. Leaves opposite, downy, grey-green, the lower ones oblong entire, the upper ones pinnately cut into lance-shaped lobes. The heads of pale yellow flowers appear in June and July.

Culture &c. as above.

C. tatarica.—A coarse-growing Siberian perennial 5-6 ft. high, with striped hairy stems, pinnate leaves, and decurrent oval lance-shaped, serrated leaflets. Flowers in summer, yellow, in large heads, paleæ or scales deep green, white inside, ciliated.

Culture &c. as above.

SCABIOSA (SCABIOUS; PINCUSHION FLOWER).—A genus containing not more than 80 distinct species of annual or perennial herbs, sometimes rather shrubby at the base, with entire, toothed, lobed or dissected leaves. Bracts of the involucre in one or two series. Receptacle more or less conical, hairy, or with scaly bracteoles shorter than the florets. Calyx limb cup-shaped, with 4 or more bristly teeth. Corolla limb 4-5-cleft, nearly equal, or often oblique, or two-lipped. Stamens 4, very rarely 2.

Culture and Propagation.—Scabious grow well in ordinary good garden soil, and are easily raised from seed sown either in spring or autumn, according as to whether they are required to bloom in summer or spring. The perennial kinds may be increased by division in early autumn or spring, and may also be increased by seeds sown as soon as ripe in the open border, afterwards transplanting the seedlings in mild showery weather when large enough to handle easily.

The following is a selection of the kinds best for the flower garden:—

S. atropurpurea (*Mournful Widow*; *Common Purple* or *Sweet Scabious*).—A very handsome annual, native of S.W. Europe, 2-3 ft. high. Lower leaves lance-shaped ovate, lyrate, coarsely toothed; upper ones pinnately cut into oblong, toothed or cut lobes. Flowers in July

and August, in deep crimson heads, very fragrant. There are several very fine varieties with all shades of crimson, purple, yellow, and white, that called *grandiflora* being particularly handsome. There is a variety with distinct yellow leaves (*foliis aureis*), and a dwarf-strain about 1 ft. high, called *nana*, which has also much variation in the colour of the flowers.

Culture &c. as above. Seeds of this species may be sown in the open border from the end of April to the end of September, to obtain a good succession of flowering plants. The seeds sown in the earlier period of the year will produce flowering plants in autumn, but it is better to thin the seedlings out for this purpose rather than transplant them. The thinnings, however, may be transferred to another part of the garden and will flower the following season. The seedlings from the later sowings should be pricked out before the end of October so that they may get established before the severe weather sets in.

The purple-crimson flowered *S. maritima* and the white-flowered *S. Metastasi* (or *S. palestina*) may be treated in the same way as *S. atropurpurea*, but they are not so well known.

S. caucasica.—A handsome perennial or biennial, 1-3 ft. high, native of the Caucasus. Lower leaves lance-shaped, pointed, glaucous, entire. Flowers in summer, pale blue, in a large head about 3 in. across. Corolla 5-cleft. Involucre very hairy. The variety *elegans* has whitish leaves; *alba* has creamy-white heads of flowers; and *heterophylla* has hairy pinnatisect leaves, and large pale purple heads of flowers.

Culture &c. as above. Although this species is a true perennial and may be increased by division of the roots in early autumn or spring, it is on the whole best grown as a biennial. If the seeds are sown about July or August the seedlings may be transplanted in mild showery weather by the end of September, and will produce fine dense masses for flowering the following year. As the flower stalks are very long this is an excellent plant for cutting.

S. correvoniana.—A handsome bushy Scabiosa, native of the Trans-Caucasus. It grows 6-9 in. high, and bears large heads of pale yellow flowers from May to August.

Culture &c. as above. Easily increased by seeds or division.

S. graminifolia.—A graceful plant 1½-2 ft. high, native of S. Europe. Leaves linear lance-shaped, entire, silvery-white. Flowers from June to October, pale blue or rosy, in heads like those of *S. caucasica*.

Culture &c. as above for *S. caucasica*.

S. Ptercephala.—An ornamental tufted perennial 4-6 in. high, native of Greece, with simple elliptic, lyrate, or pinnately divided, crenate-toothed leaves. Flowers in summer, purple, in heads about 1½ in. across, on stout stalks 2-3 in. high.

Culture &c. as above for *S. caucasica*.

S. webbiana.—A soft silky-haired plant, 6-10 in. high, native of Phrygia. Lower leaves stalked, obovate, crenate; upper ones pinnatifid with ovate or oblong entire lobes. Flowers in July, creamy-yellow, on long stalks.

Culture &c. as above.

LXII. COMPOSITÆ—Daisy Order

This is the largest order of herbs, shrubs, or trees in the vegetable kingdom, comprising between 700 and 800 genera, and about 10,000 species, comparatively few of which are of any garden value. Leaves alternate, whorled, or less frequently opposite, simple or compound, without stipules. Flowers sessile on the expanded stalk or receptacle, and surrounded by a number of more or less leafy bracts forming an involucre. Calyx superior; limb none, or feathery, or scaly, and technically known as a 'pappus.' Corolla variable in different tribes of the order. Stamens 4 or 5, anthers usually united (syngenesious), forming a tube through which the style passes.

SUB-ORDER. TUBULIFLORÆ

The flower-heads either consist of entirely hermaphrodite tubular florets with a regular 5-toothed corolla, or the central (disc) florets are tubular and hermaphrodite, while the outer (ray) florets are strap-shaped (ligulate) and female or sterile.

Tribe I. VERNONIÆ.—Herbs, shrubs, or rarely trees. Leaves usually alternate, entire, toothed, or very rarely lyrate cut. Flowers purplish, violet, or white, very rarely blue, never yellow. Florets all tubular and hermaphrodite. Branches of the style covered with bristles.

VERNONIA (*Ironweed*).—A large genus of more or less downy herbs or shrubs, usually with alternate, entire or toothed, feather-veined, stalked or sessile leaves. Flower-heads at the ends of the branches, either solitary or in cymose panicles, and usually purple, reddish or blue, rarely white.

Culture and Propagation.—Although there are nearly 400 species of *Vernonia*, only those mentioned below are of any garden value; and even these are more suitable for semi-wild situations where they have a picturesque effect. They flourish in ordinary garden soil, but the flowers, unfortunately, are often nipped by the early frosts in September and October. The easiest way to increase the plants is by dividing the roots in spring as growth is commencing. If this operation is performed in autumn it is likely to interfere with the production of flowers. Seeds may also be sown in cold frames or in gentle heat in spring, afterwards transplanting the seedlings in showery weather when large enough for the open ground.

V. novæboracensis.—A stately North American herbaceous perennial with ribbed purplish downy stems 6-8 ft. high. The shortly stalked, narrowly lance-shaped leaves are 3-4 in. long, rough and dark green above, paler beneath, and with finely toothed margins. The violet-purple flower-heads, each $\frac{1}{2}$ - $\frac{3}{4}$ in. across, appear in September and October, and are borne in large corymbose panicles.

Culture &c. as above.

Tribe II. EUPATORIÆ.—Herbs or shrubs, rarely trees. Leaves usually opposite, or the upper ones, or all, alternate, rarely in whorls, entire, toothed, or rarely dissected. Flowers rosy, purplish, bluish, or white, rarely yellowish-white or pale yellow, but never true yellow. Florets all tubular and hermaphrodite. Branches of styles usually club-shaped or enlarged at the tips.

AGERATUM (*Floss Flower*).—This genus consists of annual or biennial herbs

V. præalta.—This is also a native of North America and is very similar to *V. novæboracensis* in appearance. It is, however, much shorter, being only 3-5 ft. high, and having smooth instead of downy stems. The leaves are also smooth and narrower, but the purple flowers are borne in larger heads and appear somewhat earlier, in August and September.

Culture &c. as above.

STOKESIA (*Stokes's Aster*).—A genus containing only one species:—

S. cyanea.—A handsome vigorous N. American perennial 1½-2 ft. high, with alternate, smooth, lance-shaped, entire leaves, or somewhat spiny-ciliated at the base; lower ones stalked; upper stem-clasping. Flowers in August and September, blue, in heads about 1 in. across. Involucre roundish, the outer florets narrowly 5-cleft, scales prolonged into a leafy bristly fringed appendage.

Culture and Propagation.—This species grows freely in warm good sandy soil and leaf mould and is effective in the border. It may also be grown in pots for the conservatory. It is increased by division in spring, the slips being inserted in sharp sandy soil in a warm border. When well rooted they may be transplanted to flowering positions. Seeds may also be sown in spring under glass or as soon as ripe in autumn in cold frames. The seedlings are pricked out into light soil when large enough, and are afterwards transferred to the open border.

with opposite leaves and blue or white flowers. Involucre of many imbricated

linear bracts. Receptacle naked. Pappus composed of several curved scales, broad at the base.

Culture and Propagation.—Ageratums like a light rich soil, and are among some of the most showy plants used for beds and borders during the summer. The dwarfier sorts make excellent edgings, or they may be planted to form a carpet between taller-growing Zonal Pelargoniums. They seed freely, and a small quantity saved every year will be sufficient to raise hundreds of plants in spring. The seed must be sown about February or March in slight bottom heat. When large enough the seedlings may be pricked out into shallow boxes, or separately into small pots to make sturdy plants by the end of May. During the summer they may also be increased by cuttings, and if seeds are prevented from ripening, the plants become more or less perennial. But they are scarcely worth this trouble, as they must be wintered in greenhouses until the following May, and this is an important point where space under glass is limited, and required for more important plants.

Ordinary light sandy garden soil will suit the plants well, and by pinching out the tips of the young shoots numerous side branches will be developed and increase the number of feathery flower-heads.

A. Lasseauxi.—A native of Monte Video, 1½-2 ft. high, with lanceolate elliptic leaves, and heads of rose-coloured flowers in summer.

Culture &c. as above.

A. mexicanum.—This is the best known species, and its varieties are largely grown for bedding purposes every year. It is a native of Mexico, and grows naturally about 2 ft. high, with ovate, coarsely toothed leaves, and a profusion of lilac-blue, fluffy flowers in summer and autumn. There are several dwarf, free-flowering varieties, among which the following are the best: *Cupid*, rich blue; *Countess of Stair*, pale blue; *Queen*, silvery grey; *Snowflake*, white; *Swanley blue*, very deep blue; *Mauve Beauty*, rich mauve; and others more or less desirable.

Another Mexican species is *A. Wendlandi* which grows 4-8 in. high, and forms dense masses of grey-green downy leaves, above which appear large greyish-blue flower-heads. There is also a white-

flowered variety which is quite as free-growing as the type.

Culture &c. as above.

EUPATORIUM.—A genus containing upwards of 400 species, very few of which are of garden value. Leaves opposite, rarely alternate, entire, toothed, or rarely dissected. Flower-heads purplish, bluish, or white, in terminal corymbs. Receptacle naked. Pappus rough. Bracts of the involucre imbricate in 2-3 rows.

Culture and Propagation.—The Eupatoriums are coarse-growing plants more suitable for rough parts of the garden than the flower border. They grow in any soil, and may be increased by division of the roots in autumn or in spring. Seeds may also be sown in bottom heat about March, and the young plants when large enough may be pricked out into shallow boxes or pots, and grown on until about the end of May, when they may be transferred to the open ground. Seeds may also be sown in cold frames as soon as ripe, but the seedlings cannot be planted out with safety until the following spring.

E. ageratoides.—A native of North America 1-4 ft. high, with ovate, rather heart-shaped, stalked and coarsely toothed leaves. Flowers in summer, pure white, numerous, in compound corymbs.

Culture &c. as above.

E. aromaticum.—A sturdy N. American species 3-4 ft. high. Leaves usually shortly stalked, rounded, toothed. Flowers late in summer, white, in loose corymbs.

Culture &c. as above.

E. cannabinum (*Hemp Agrimony*).—A handsome native perennial, with downy stems 2-4 ft. high. Leaves with 3-5 lance-shaped, serrate leaflets. Flowers in July, reddish-purple, in terminal tufts.

Culture &c. as above.

E. glechonophyllum.—A tufted Chilean species 1½-2 ft. high with oval acute, coarsely toothed leaves. Flower-heads pure white borne in corymbose clusters during the summer months.

Culture &c. as above. This species is best treated as an annual like the Ageratums, and may be raised from seeds sown in gentle heat in spring, or in autumn in cold frames. In both cases the seedlings can be placed in the open border at the end of May.

E. purpureum (*Trumpet Weed*).—A N. American species 3-9 ft. high or more. Leaves 3-6 in a whorl, somewhat ovate or lance-shaped, pointed, roughish, unequally toothed, downy beneath. Flowers in autumn, purplish, in corymbs. Grown in rich soil and in bold masses, this species has a very bold effect in the garden.

Culture &c. as above.

LIATRIS (SNAKEROOT).—This genus contains about 16 species of perennial herbs, all natives of N. America. Leaves alternate or scattered, narrow, entire, 1-5-nerved. Flower-heads purplish or white, spicate, racemose, or paniced. Bracts of the involucre small, imbricated, in many rows. Receptacles naked. Pappus feathery.

Culture and Propagation.—When grown in masses these plants are very effective in the flower border with their long dense spikes of flowers. It may be remarked that the flower-heads of these plants usually open from the top of the spikes downwards, and not from the bottom upwards as found in most other plants. They thrive in ordinary garden soil, and may be readily increased by division of the roots in spring; or by seeds sown as soon as ripe in the autumn in cold frames, afterwards pricking out the seedlings and growing on until about the end of May, when they may be planted out.

L. elegans.—An elegant plant 2-4 ft. high, with smooth, spotted leaves; lower ones spoon-shaped, 3-5-nerved; upper ones strap-shaped, short, sometimes spiny-tipped. Flowers in summer and autumn, purplish, in spikes a foot or more long.

Culture &c. as above. Easily increased by division in spring.

L. graminifolia.—A tuberous-rooted species with pointed, remotely dotted leaves, fringed at the base. Flowers in autumn, purple, loosely spicate, in the axils of the upper leaves or bracts.

The variety *dubia* (*L. propinqua*) has upright spikes of rather large heads of flowers, with the bracts of the involucre

narrower and thinner than in the type. The variety *pilosa* has very narrow involucre bracts.

Culture &c. as above.

L. odoratissima (*Trilisa odoratissima*). *Vanilla Plant.*—A pretty plant 2-4 ft. high. Leaves thick, emitting a fragrant Vanilla-like odour when bruised; lower ones large, obovate spoon-shaped, tapering at the base, often slightly and bluntly toothed; upper ones oblong, stem-clasping, becoming smaller and scattered higher up. Flowers in September, bright purple, numerous; bracts of the involucre glandular.

Culture &c. as above.

L. pycnostachya.—A pretty species with stout, leafy stems 3-5 ft. high, and rigid sessile leaves; lower ones narrow lance-shaped, blunt, 5-7-nerved; upper ones short, crowded, narrow. Flowers in summer and autumn, pale purple, in dense cylindrical spikes 1-1½ ft. long.

Culture &c. as above. This is best treated as a biennial. It grows well on dry soils, and the seeds may be sown in cold frames in autumn, and the seedlings transferred to the open ground in mild showery weather about the end of April or May.

L. scariosa.—A plant about 2 ft. high with very long and narrow leaves, and purple flower-heads about 2 in. across, in September.

Culture &c. as above. Easily increased by division in spring.

L. spicata.—A handsome perennial 1-3 ft. high, with lance-shaped acute leaves, ciliated at the base. Flowers in September, purple, in spikes 6-15 in. long. Bracts of involucre oblong or oval.

Culture &c. as above. Easily increased by division of the roots in spring.

L. squarrosa.—A showy species 2-3 ft. high. Lower leaves long, ½ in. wide, 3-5-nerved; upper ones strap-shaped, stiffish. Flowers in summer and autumn, bright purple, on leafy and downy stems. Bracts of involucre with elongated leafy tips.

Culture &c. as above.

Tribe III. ASTEROIDEÆ.—Leaves usually alternate, very rarely opposite, entire, lobed, or rarely dissected. Outer (ray) florets often strap-shaped, females sterile; inner (disc) florets hermaphrodite. Branches of the style hairy above.

XANTHOCEPHALUM.—A small genus of herbs or shrubs with alternate

narrow entire or toothed leaves and yellow flower-heads borne either singly or

in loose clusters at the ends of the shoots. Involucre hemispherical or broadly bell-shaped. Receptacle flat, pitted. Ray florets strap-shaped spreading, 5-cleft at the apex.

X. gymnospermoides.—A vigorous downy annual 3-4 ft. high, native of Arizona, with lance-shaped sharply toothed leaves tapering into a longish stalk. The bright yellow flower-heads, each about $\frac{3}{4}$ in. across, appear late in summer in an inverted pyramidal cluster a foot or more in diameter.

Culture and Propagation.—This little-known plant flourishes in ordinary good garden soil in warm sunny positions, and owing to its late-flowering propensities is well worth a place in the flower border. It may be raised from seeds sown in gentle heat in spring and planted out in May, see p. 78.

GRINDELIA.—A genus with about 20 species of biennial or perennial shrubs or herbs, with alternate, sessile or half stem-clasping leaves, often rigid, toothed, or serrately fringed. Flowers in solitary heads at the ends of the branches. Pappus composed of 28 narrow deciduous bristles.

Culture and Propagation.—Grindelias grow readily in a mixture of peat and loam. Seeds may be sown in slight heat about March, and the seedlings planted out in June. The plants may also be increased by cuttings in a cool frame, but they require the protection of a cool frame or greenhouse in winter, except perhaps on the south coast in the mildest parts and in sheltered spots. For the cultivation of biennials in general see p. 60, as most of the Grindelias may be treated as such.

G. glutinosa.—A pretty Peruvian shrubby plant about 2 ft. high, with evergreen, ovate-oblong, serrated leaves. Flowers for the greater portion of the year, yellow, 1-2 in. across, with clammy involucre.

Culture &c. as above.

G. grandiflora.—A biennial 2½-3 ft. high, native of Texas. Lower leaves spoon-shaped; upper ones sessile, clasping, toothed. Flowers during summer, deep yellow or orange, about 1½ in. across, clammy before opening.

Culture &c. as above.

G. inuloides.—A shrubby Mexican biennial, about 1½ ft. high. Leaves

sessile, oblong lance-shaped acute, serrated towards the apex. Flowers from July to September, yellow.

Culture &c. as above.

G. squarrosa (*Donia squarrosa*).—A N. American perennial, about 2 ft. high, with oblong, clasping, sharply toothed leaves. Flowers from July to September, yellow.

Culture &c. as above.

XANTHISMA.—A genus having but one species:—

X. texana (*Centaureidium Drummondii*).—A smooth erect annual or biennial 1½-2 ft. high, native of Texas, having alternate linear lance-shaped entire leaves. The bright yellow flower-heads about 1½ in. across are borne singly during the summer months at the tips of the numerous shoots.

Culture and Propagation.—This plant is suitable for the flower border with other composite annuals, and will flourish in ordinary garden soil. Seeds should be sown in gentle heat in February and March, so as to have strong seedlings for planting out 1-1½ ft. apart in bold masses at the end of May.

SOLIDAGO (GOLDEN ROD).—A genus of about 80 species of tall-growing, rather coarse, perennial herbs, with alternate, entire or toothed leaves, and terminal racemes or clusters of small yellow flowers. Involucre oblong or narrow bell-shaped, with bracts in many series. Ray florets strap-shaped, spreading, rarely small and erect. Receptacles naked. Pappus in one series of rough, rigid bristles.

Culture and Propagation.—The Golden Rods are coarse growers and rank feeders, and soon impoverish a rich soil. In rough places or old shrubberies they do very well, and brighten the surroundings with their golden-yellow trusses. They may be increased by division in autumn or early spring. A good top dressing of manure every autumn and winter will enable the plants to grow for several years in the same place. Nearly all are natives of North America. The following are a few of the best for the garden, but several others are to be met with in botanical collections. The flowers of all the species are yellow, and although insignificant individually, are nevertheless showy on account of their great numbers.

S. canadensis.—A species with roughly hairy stems, 3–6 ft. high, and lance-shaped, pointed, sharply serrate, or entire leaves, more or less downy beneath. Flowers in August.

Culture &c. as above.

S. Drummondii.—Grows 1–3 ft. high, with broadly ovate or oval leaves, coarsely and sharply toothed, or almost entire, velvety downy beneath. Flowers in summer; ray florets 4 or 5.

Culture &c. as above.

S. lanceolata (*Euthamia graminifolia*).—A downy plant 2–3 ft. high, with linear lance-shaped, entire leaves, and obconical heads of flowers in dense clusters, produced in September; ray florets 15–20.

Culture &c. as above.

S. rigida.—A vigorous species 3–5 ft. high, with oval or oblong, thick, rigid leaves. Flowers in September, in compound corymbs; ray florets 7–10.

Culture &c. as above.

S. rugosa (*S. altissima*).—A roughly hairy plant, 2–7 ft. high. Leaves ovate-lance-shaped, elliptic or oblong, often thickish and very wrinkled, coarsely and sharply toothed. Flowers in August and September, in spreading, paniced racemes. Ray florets 6–9.

Culture &c. as above.

S. sempervirens.—A thick, smooth-stemmed plant 1–6 ft. high, with smooth, entire, lance-shaped leaves. Flowers in September, in short racemes. Ray florets 8–10.

Culture &c. as above.

S. serotina (*S. fragrans*).—A more or less glaucous-stemmed plant, about 3 ft. high. Leaves lance-shaped, pointed, serrated, roughish above, smoothish beneath. Flowers from August to October, in pyramidal panicles.

Culture &c. as above.

S. speciosa.—A handsome plant, with stout, smooth stems 3–6 ft. high. Leaves more or less oval, thickish, rough, slightly serrate; lower ones 4–6 in. long. Flowers in October, somewhat crowded in pyramidal clusters.

Culture &c. as above.

S. Virgaurea.—A native of British Islands, as well as the N. temperate zone, 6–24 in. high, with linear or lance-shaped oblong, obscurely toothed leaves, 1–4 in.

long. Flowers from July to September, crowded. Ray florets 10–12, spreading. *Cambrica* is a dwarf variety.

Culture &c. as above.

APHANOSTEPHUS.—A small genus of many-stemmed downy herbs with alternate leaves and solitary flower-heads at the ends of the shoots. Involucre hemispherical. Receptacle convex or somewhat conical. Ray florets white or purple; disc yellow.

A. ramosissimus.—A pretty annual about 4 in. high, native of Texas. It makes dense tufts and produces during the summer months numerous stems each bearing a flower-head about 1 in. across with violet-blue or purple ray florets surrounding a yellow disc.

Culture and Propagation.—This flourishes in ordinary garden soil in warm sunny spots in the rock garden or flower border. It should be raised from seeds sown annually in February or March in gentle heat, so that the seedlings will be large and sturdy for the open air by the end of May.

BRACHYCOME.—A genus of pretty annuals or perennials, closely related to the Daisy (*Bellis*) in structure. Braets of the involucre with membranous margins. Receptacle pitted, naked. Fruit flattened, surmounted with a bristly pappus.

B. iberidifolia (*Swan River Daisy*). A pretty Australian annual 8–12 in. high, with pinnate leaves cut into linear segments. Flowers during summer and autumn, bright blue (or white in the variety *alba*), about 1 in. across, with a dark or pale centre, in loose terminal clusters. There is also a form with rosy-lilac blossoms, and one called *bicolor* in which the blue flowers have a distinct and well-defined white band at the base of the petals.

Culture and Propagation.—If grown in a bright sunny spot the Swan River Daisy flowers profusely. Seeds may be sown in gentle heat in March, and the seedlings pricked out or potted on until the first week of June, when they can be planted out; or they may be sown in the open border at the end of April, thinning the seedlings out to about 6 in. apart. Seeds are often sown in a cool frame in September, and the plants grown on in pots in a cool greenhouse during the

winter, but it is unnecessary to go to this trouble for the hardy flower border.

BELLIS (DAISY).—This genus contains 3 or 4 species of small herbaceous perennials, with all radical toothed and stalked leaves. Flower heads solitary involucre bell-shaped with bracts in 1-2 series. Receptacle conical. Pappus absent.

Culture and Propagation.—The cultivated forms of the common Daisy are beautiful and easily grown in moist loamy soils. After flowering they may be increased by dividing the crowns—each one making a separate plant. Division may also take place in spring, or indeed at almost any period of the year when the weather is mild and showery, but the separated portions should be placed rather firmly in rich loamy soil in a somewhat shaded position. Seeds may also be sown in March, but the seedlings often come single and are rarely worth multiplying. The only possible way to obtain a good collection of first class double-flowered Daisies is by means of division.

B. perennis (*Common Daisy*).—The double white, crimson, and striped varieties are the best. *Pink Beauty* is a charming pink with flat petals; *Rob Roy*, a rich red or crimson-quilled kind; *White Globe*, with large, white-quilled petals; *Aucubæfolia* is a handsome variegated sport with blotched and veined yellow leaves. The *Hen and Chicken Daisy* is similar in flower and leaf to the other double kinds, but when in bloom smaller flowers are developed all round the larger central one.

Culture &c. as above.

B. rotundifolia cærulescens (*Blue Daisy of Morocco*).—A beautiful perennial native of Morocco, with ovate or roundish, sinuate-toothed leaves on slender stalks 1-3 in. long. Flowers in summer, $\frac{3}{4}$ -1 $\frac{1}{4}$ in. across, with flowers like the Common Daisy, the ray-florets varying from white to blue or magenta-purple. This plant requires protection in winter except in southern parts of the country.

Culture &c. as above.

BELLIUM.—This genus differs from the Daisy in having a pappus of 6-8 broad scales torn at the apex, and alternating with an equal number of long rough bristles.

Culture and Propagation.—The plants thrive in sandy loam and peat, but

are apt to exhaust themselves by their free-flowering propensities. They are increased by seeds sown in cold frames as soon as ripe; in hotbeds about March; or in the open border about the end of April and May. Except in the latter case, when the seedlings may be simply thinned out, they are pricked out into light soil, and by the end of May or beginning of June will be ready for the open border. The plants may also be increased by division of the roots in spring or early autumn. They are all suitable for the rockery.

B. bellidioides.—A pretty Italian annual about 4 in. high, with creeping stems, and spoon-shaped radical leaves. Flowers from June to September, white, solitary.

Culture &c. as above.

B. crassifolium.—A Sardinian perennial about 6 in. high, with many ascending stems, and thick rather downy obovate entire leaves, narrowed at the base. Flowers in June, whitish-yellow, on downy scapes longer than the leaves.

Culture &c. as above.

B. minutum.—A pretty little species about 3 in. high, native of the Levant. Leaves narrowly spoon-shaped, slightly hairy. Flowers from June to September, white and yellow, $\frac{1}{2}$ in. across, on slender scapes.

Culture &c. as above.

CHARIEIS.—A genus having only the following species:—

C. heterophylla (*Kaulfussia ameloides*).—A beautiful compact-growing hairy annual, about 1 ft. high, native of S. Africa, and far better known in gardens under the name of *Kaulfussia*. It has oblong lance-shaped entire leaves, opposite below and alternate above. The beautiful flower-heads, with deep blue ray florets surrounding a blue or yellow disc, appear during April and May and stand well above the foliage.

There are several varieties known, such as *alba*, *atroviolacea*, *kermesina*, *rosea* &c., according to the colour of the flower-heads.

Culture and Propagation.—This is a beautiful plant for the rock garden or border, and flourishes in ordinary garden soil in open sunny situations. The seeds may be sown in cold frames when ripe, or in gentle heat about March, to obtain

seedlings for the open air in May. To keep up a succession of bloom seeds may also be sown in the open border during April, afterwards thinning the seedlings out 12-18 in. apart.

BOLTONIA.—A genus of erect-growing Aster-like perennials with alternate, quite entire or coarsely toothed leaves, and medium-sized flower-heads in loose irregular panicles, or solitary at the tips of the shoots. Ray florets white or bluish. Involucre hemispherical. Receptacle convex or conical.

Culture and Propagation.—Boltonias may be grown exactly in the same way as the Starwort or Michaelmas Daisy Asters. They flourish in ordinary good and well-drained garden soil, and may be used in bold masses in the herbaceous border, the rockery, or shrubbery. They are readily increased by dividing the roots about September, or in spring, in mild showery weather. Seeds may also be sown as soon as ripe either in the open border or in cold frames, and cuttings of the young shoots, taken about April, and inserted in sandy soil in a cold frame shaded from the sun for a time, will soon root and make good plants. See *Aster* below, p. 500.

B. asteroides.—A native of the mountains of Carolina, 3-4 ft. high, with linear lance-shaped leaves, and rosy-white flowers with a yellow centre, produced in loose corymbs from June to August.

Culture &c. as above.

B. glastifolia.—A smoothish glaucous-looking N. American perennial 6-8 ft. high, with lance-shaped leaves, the lower ones of which are toothed. Flowers bluish-white with a yellow disc, produced in corymbose panicles in August and September.

Culture &c. as above.

B. latisquama.—A free-flowering N. American perennial 3-4 ft. high, with bright green lance-shaped leaves, and numerous rosy or bright lilac flower-heads borne in large clusters from July to September.

Culture &c. as above.

CALLISTEPHUS (CHINA ASTER).
The only species in this genus is:—

C. hortensis (*C. chinensis*; *Aster sinensis*).—A beautiful annual 1-2 ft. high, native of China. Leaves ovate, coarsely toothed, lower ones stalked; upper sessile, wedge-shaped at the base.

Flowers from August to November, 2-4 in. or more across, beautiful mauve-purple with a bright yellow centre, very much resembling those of *Erigeron speciosus* (p. 506), but of a somewhat deeper shade of colour, broader ray-florets, and much larger flowers.

This is the description of the original species from which the numerous varieties of China Aster in cultivation have been produced. So much attention has been devoted to developing the progeny that the parent has been overlooked for very many years, and had dropped out of cultivation. Within the last year or two, however, it has been re-introduced, and it would be difficult to find a more graceful or useful plant for the flower border. It should be planted in bold masses to obtain striking effects. A light and warm rich soil produces the best results, and in the event of very dry weather copious supplies of water should be given either late in the afternoon or evening, or early in the morning, say between 6 and 8 o'clock. The plants will grow in shady places, but they are much finer in open sunny situations.

The florist's China Aster has been divided into about 30 distinct groups, such as the Pæony and Chrysanthemum-flowered; the Comet or Poodle, and Ostrich-flowered; the Victoria, the Emperor, the Anemone or Quilled; the Co-cardeau or Crown; the Rose and the Porcupine, the Globe, the Pompon, and such like names—all more or less unmeaning to the amateur, but distinct enough to the specialist. The flowers of all these kinds are of course 'double,' and bear no resemblance whatever to the original species described above, except in so far that all the perfect tubular florets of the centre have been changed by cultivation into strap-shaped ones like those of the outer row.

China Asters are very fine in groups or masses in borders or in beds by themselves. They vary a good deal in height, and it is advisable when grouping to keep each section in a group by itself, to avoid unevenness. The colours vary from pure white to rose, pink, light and dark blue, mauve, scarlet, with intermediate shades, except yellow.

Culture and Propagation.—A deep rich loamy soil and open situations are best for China Asters. In hot dry summers the leaves are apt to become

very much wrinkled and the flowers with unsightly ragged centres, unless a good supply of water is given regularly. To prevent evaporation as much as possible, and to keep the soil cool, a top dressing of spent mushroom-beds or other rotted manure may be given.

The plants are easily raised from seeds. These are usually sown in bottom heat in March, but they germinate freely in cold frames about the end of April, either in pots or shallow boxes or pans. They require to be pricked out, and made as sturdy as possible with light and air by the end of May, when they may be planted out.

Seeds ripen freely in the British Islands, but they cannot be relied upon to produce such fine flowers as the plants which have been raised from seed saved on the Continent, where the seasons as a rule have a more ripening effect than ours.

ASTER (STARWORT; MICHAELMAS DAISY).—A genus containing about 200 species of herbaceous perennials (rarely biennials) mostly natives of N. America. Leaves alternate, entire, toothed or incised. Flower-heads in racemes or panicles. Involucre bell-shaped or hemispherical; bracts few or in many series. Receptacle flat or convex. Pappus hairs few or plentiful.

In speaking of these plants the term 'Starwort' seems to be on the whole more appropriate than 'Michaelmas Daisy,' although the latter term undoubtedly indicates the period when a large number, but by no means all, bloom. But such plants as *A. diplostephoïdes* for instance cannot be appropriately called Michaelmas Daisies.

Culture and Propagation.—Most Starworts are of easy culture in ordinary garden soil, and are readily increased by dividing the root growths in early spring. Seeds may also be sown, although many varieties readily reproduce themselves by this means naturally. They may be sown in light prepared soil in the open border as soon as ripe, but there will be a better chance of success by sowing in cold frames. The seedlings may be pricked out and grown on until the following September, or spring, when they may be transferred to their places in the flower border. Cuttings of the young shoots from the roots may also be taken about

April or May, and inserted in sandy soil in a cool frame, or better still with a little bottom heat. They will soon root if kept shaded and sprinkled overhead for a short time, afterwards giving more air and light as they show signs of becoming established.

Of late years there has been a great revival in regard to the cultivation of Starworts, but notwithstanding several efforts to reduce them to order, they are still in a very mixed condition botanically. The fact is that many kinds readily intercross, and their progeny exhibit traces sometimes of one parent, sometimes of another, and these become further crossed with other species or varieties, and so on indefinitely.

As garden plants, Starworts are among the most beautiful and graceful of autumn flowers. With the disappearance of the Phloxes, and perennial Sunflowers, the Dahlias, Golden Rods, and many other beautiful flowers, the Starworts become conspicuous for their beauty and their lasting properties. They produce a wealth of starry blossom, beginning in July or August with such kinds as *acris*, *Amellus*, *lævis*, *Novi-Belgii*, and ending in November and December with *diffusus*, *ericoides*, and *grandiflorus*. For decorative purposes they are unsurpassed at this latter period of the year.

In habit of growth Starworts vary a good deal both in height and method of branching. Some are scarcely a foot high, while others often attain a height of 5 or 6 feet or more, according to soil and situation. The taller-growing kinds are valuable for the flower border, but to see their beauty to advantage they should be planted in bold masses. The dwarfer and more slender kinds are effective in the rock garden, the margins of shrubberies, and borders.

The following is a selection of the kinds worth growing. They are all natives of N. America except where otherwise stated.

A. acris.—A native of S. Europe 2 ft. or more high, with linear lance-shaped leaves, and blue flowers in August. The variety *dracunculoides* is a tall, free-flowered form; *nanus* is very dwarf, and useful for rockeries.

Culture &c. as above.

A. acuminatus.—About 2 ft. high, with broadly lance-shaped, long pointed leaves,

and corymbs of white flowers in September.

Culture &c. as above.

A. alpinus.—A very attractive species 6-9 in. high, native of Europe, with more or less lance-shaped leaves. Flowers in July, bright purple, 1-2 in. across. There are white and rose-coloured varieties, and also a vigorous one called *speciosus*, with larger flowers than in the type. The variety *altaicus* from Siberia is a very fine one, with bluish-purple flower-heads about 2 in. across. The form called *albus* has white flowers, and the one known as *ruber* red ones.

Culture &c. as above.

A. Amellus.—A fine Italian species about 2 ft. high, with roughish, oblong-lance-shaped leaves, and heads of purple flowers in August. The variety *amelloides* has dark lilac-purple flowers over 2 in. across; *bessarabicus* is rich lilac-purple; *linarifolius* grows taller than the type, has narrower leaves and deeper coloured flowers; *cassubicus* is chiefly remarkable for the bright golden centre surrounded with regular deflexed ray florets; and *major* has flowers about 2½-3 in. across, of a rich violet-purple colour.

Culture &c. as above.

A. amethystinus.—A pretty plant about 4 ft. high, with masses of small, bright lilac flowers from October to December.

Culture &c. as above.

A. Bigelovi.—A bushy perennial 1½-2 ft. high, with oval lance-shaped leaves and large bright lilac flowers produced in September and October.

Culture &c. as above.

A. cordifolius.—About 2 ft. high, with heart-shaped, finely serrated, stalked leaves, hairy beneath, and crowded racemes of small blue flowers in September and October. The variety *Diana* (or *Photograph*) is about 4 ft. high, erect and bushy, with pale lilac flowers; *albula*, flowers lilac and white, height 4 ft.; *elegans* (or *undulatus*), about 4 ft. high, with small, bright lilac flowers.

Culture &c. as above.

A. corymbosus (*Biotia corymbosa*).—This species has blackish-purple, brittle stems 2-3 ft. high, and heart-shaped, acute, coarsely toothed leaves about 3 in. long, lobed at the base. Flowers in August and September, about 1 in. across, white.

There is a variety *Perseus* with bushy heads of numerous flowers.

Culture &c. as above.

A. diffusus.—A somewhat spreading species about 2 ft. high, with elliptic lance-shaped, serrate leaves, and heads of white flowers in October. The variety *horizontalis* branches horizontally, and has masses of red and white flowers. *Pendulus* (or *Nondescript*) grows taller and has white flowers about 1 in. across.

Culture &c. as above.

A. diplostephioides.—A beautiful downy or hairy perennial with stout stems 6-18 in. high, native of the Sikkim Himalayas. Leaves 2-4 in. long, obovate or oblanceolate, entire, narrowed into short or long stalks. Flowers in May and June, 2-3 in. across; ray florets bright purple; disc purple at first, afterwards yellow. Involucre broadly hemispherical, with lance-shaped bracts.

This species likes partially shaded spots and rich sandy peat loam.

Culture &c. as above.

A. dumosus.—A dwarf and compact species 1½-2 ft. high, with smooth, linear leaves and beautiful white or mauvy-pink flowers about ½ in. across, in October.

Culture &c. as above.

A. ericoides.—A pretty species about 3 ft. high, with smooth, linear, Heath-like leaves. Flowers in September, white, numerous. The variety *Olio* has pale pink flowers about 1 in. across.

Culture &c. as above.

A. graminifolius.—A pretty little species less than 6 in. high, with erect stiffish slender stems and linear green leaves ½-¾ in. long. The white Daisy-like flower-heads appear in May and June, and are borne singly at the ends of the shoots.

Culture &c. as above.

A. grandiflorus.—A fine species 2-3 ft. high, with rigid linear acute and somewhat clasping leaves. Flowers in November and December, deep violet, large.

Culture &c. as above.

A. Herveyi.—A rather roughish slender-growing perennial 1-2 ft. high, with ovate lance-shaped obscurely serrate leaves, and bright lilac or violet flowers about 1½ in. across produced in autumn.

Culture &c. as above

A. lævis.—A beautiful species varying from 2 to 6 ft. high, with somewhat stem-clasping, oblong entire or slightly serrated, shining leaves. Flowers from August to October, various shades of lilac and purple. There are many varieties, of which the best are *Ariadne*, *Apollo*, *Arachne*, *Arcturus*, *Calliope*, *decorus*, *floribundus*, *Harvardi*, *Pygmalion*, *Vesta*, and *Virgil*.

Culture &c. as above.

A. linarifolius.—This species rarely exceeds 2 ft. in height, and has the stems clothed with narrow linear Flax-like leaves all the way up to the flower-heads. The latter are rather small, with deep violet ray florets and a yellow centre.

Culture &c. as above. This species must not be confused with the variety of *A. Amellus* having the same name.

A. lindleyanus.—A showy perennial 1-2 ft. high. Lower leaves ovate and somewhat heart-shaped with winged stalks; upper ones sessile, serrate, and tapering at each end. Flowers pale violet, about 1½ in. across, produced in loose panicles in autumn.

Culture &c. as above.

A. Linosyris (*Chrysocoma Linosyris*; *Linosyris vulgaris*).—*Goldilocks*. A distinct native plant about 2 ft. high, with linear Flax-like leaves, and showy yellow flowers produced in August and September.

Culture &c. as above.

A. longifolius.—About 3 ft. high, with very long, smooth, linear-lance-shaped leaves, rarely toothed. Flowers in October, white, 1 in. across, in dense panicles. The variety *formosus* has pink flowers.

Culture &c. as above.

A. Michelli.—A pretty dwarf herbaceous perennial about 1 ft. high, native of Austria. Leaves in a rosette, shortly stalked, obovate, wavy-edged. Flowers in June, white, solitary. This plant was formerly known as *Bellidiastrum*.

Culture &c. as above. Easily grown in loam, leaf soil and peat, and increased by division in early spring or autumn.

A. multiflorus.—A free-flowering species 3-4 ft. high, with much-branched, downy stems, and smooth linear leaves. Flowers in September, white, small, borne in large corymbs.

Culture &c. as above.

A. Novæ-Angliæ.—This fine species grows from 4 to 6 ft. high, with simple hairy stems, and linear lance-shaped, hairy, stem-clasping leaves, lobed at the base. Flowers in September, purple. The variety *pulchellus* has large, deep violet flowers; *præcox*, purple flowers; *roseus*, pale rose, and *rubra*, deep rose flowers; *Wm. Bowman*, rich rose-purple, and *Woolston*, fine blue shade.

Culture &c. as above.

A. Novi-Belgii.—A handsome species 3-6 ft. high. Leaves somewhat stem-clasping, lance-shaped, smooth, rough-edged, slightly serrated. Flowers from August to October, pale blue.

Like *A. lævis*, this species also has many forms, some very fine, among them being:—*Archer-Hind*, flowers 1-2 in. across, pale rose-lilac; *Argus*, *Aurora*, *Berenice*, *densus*, *Harpur Crewe*, flowers 1-2 in. across, white, tinged with rose when old; *Janus*, white and rosy-purple; *John Wood*, white; *lævigatus*, deep rose; *Minerva*, deep rose-lilac; *nanus*, dwarf grower with rose flowers; *Proserpine*, rose-lilac; *Purity*, white; *Ravenna*, rosy-lilac; *Robert Parker*, lilac-purple.

Culture &c. as above.

A. paniculatus.—A pretty species about 4 ft. high, with ovate lance-shaped, somewhat serrated, stalked leaves. Flowers in August and September, light blue. The variety *W. J. Grant* has bluish-white or pale mauve flowers, very free, useful for cutting. *Dot* has small white flowers tipped with rose.

Culture &c. as above.

A. patens.—A fine plant with procumbent stems, 1-2 ft. long. Leaves oval-pointed, with a broad clasping base. Flowers in autumn, about 1 in. across, purple-blue.

Culture &c. as above.

A. peregrinus.—A pretty little species about 1 ft. high, suitable for the rockery. Leaves lance-shaped, acutish, entire. Flowers in July and August, bluish-purple, 2 in. across.

Culture &c. as above.

A. Pseudamellus.—A beautiful bushy Himalayan species 6-18 in. high, with oblong blunt and obscurely toothed leaves. The bluish-purple flower-heads, each 1-2 in. across, are borne in August and September in corymbose clusters at the top of the stems.

Culture &c. as above. In many

gardens this species does not succeed very well.

A. ptarmicoides.—A pretty plant about 2 ft. high, with linear roughly toothed leaves, and small white flowers in September. This does not grow well in all places.

Culture &c. as above.

A. puniceus.—A graceful plant 4-6 ft. high, with stem-clasping, lance-shaped, serrate, roughish leaves. Flowers in August and September, blue or rosy-lilac, about 1 in. across, in large pyramidal panicles. The variety *incandulus* has pale lilac flowers 1½ in. across; *pulcherrimus* has white flowers tinted with lilac; ray-florets deflexed.

Culture &c. as above.

A. pyrenæus.—A Pyrenean species 1-1½ ft. high, with roughish, oblong lance-shaped acute leaves without stalks and serrated towards the apex. Flowers in July, large, lilac-blue, with a yellow centre.

Culture &c. as above.

A. Reerversi.—A pretty species 9-12 in. high, with linear acute leaves, and dense panicles of small white flowers, with a yellow centre, produced in autumn.

Culture &c. as above.

A. sericeus.—A greyish, slender-stemmed plant 1-2 ft. high. Leaves lance-shaped, silky, 1-3 in. long. Flowers late in summer and autumn, deep blue, about 1½ in. across.

Culture &c. as above.

A. Shorti.—A pretty species 2-4 ft. high, with more or less lance-shaped tapering leaves 3-5 in. long. Flowers in autumn, purple-blue, about 1 in. across.

Culture &c. as above.

A. sibiricus.—A Siberian species about 2 ft. high. Leaves lance-shaped, serrate, hairy, rather stem-clasping. Flowers in August, blue, with hairy bracts.

Culture &c. as above.

A. sikkimensis.—A native of Sikkim, about 3 ft. high. Leaves lance-shaped pointed, spiny-toothed, upper ones without stalks. Flowers in October, purple.

Culture &c. as above.

A. spectabilis.—A handsome species about 2 ft. high, with roughish, lance-shaped, stem-clasping leaves, lower ones

more or less serrate. Flowers in August, blue.

Culture &c. as above.

A. Stracheyi.—A native of the Western Himalayas. Lower leaves 1-2 in. long, oblanceolate or obovate, shortly stalked. Flowers in May, pale lilac-blue, 1-1½ in. across, on red-brown scapes 3-6 in. high.

Culture and Propagation.—This is a charming plant for furnishing partially shaded spots in the rockery. It has creeping stems which root at the tips, so that left undisturbed a plant soon spreads over a good area, and makes a beautiful carpet of green beneath the lilac-blue blossoms. It may be easily increased in autumn or spring by detaching the runner-like shoots.

A. Sturi.—This is one of the smallest growing Asters with a dense compact habit. The small Box-like leaves are almost evergreen and make a pretty carpet on the ground. The flowers are large for the size of the plant; they are pure white, and last for several weeks in early spring.

Culture &c. as above. An excellent rock plant.

A. tardiflorus.—A vigorous species about 3 ft. high, with oblong lance-shaped leaves. Flowers in autumn, pale rosy-lilac; centre at first yellow, afterwards purplish.

Culture &c. as above.

A. Thomsoni.—A handsome Himalayan perennial 1-3 ft. high, the whole plant being more or less hairy and whitish-green in appearance. Leaves 3-4 in. long, oval, with coarsely toothed margins. The lilac flower-heads, with conspicuous yellow centres, appear from July to October, and are borne in loose corymbs, or sometimes solitary.

Culture &c. as above. Easily increased by division in autumn or spring; or by seeds.

A. Townshendi.—A fine species 3-4 ft. high, native of the Rocky Mountains. It has somewhat hairy stems and blunt spoon-shaped leaves 8-12 in. long, the upper ones oblong ovate-acute. It bears a profusion of bright violet-blue flower-heads 2-3 in. across in July and August.

Culture &c. as above.

A. Tradescanti. — A graceful species about 4 ft. high, with lance-shaped, serrated, Heath-like leaves. Flowers in August and September, white, numerous.

Culture &c. as above.

A. tricephalus. — A native of Sikkim. Lower leaves obovate, spoon-shaped, with long winged stalks; upper ones oblong, somewhat stem-clasping. Flowers in July and August, purple, large, and showy.

Culture &c. as above. This species grows 1-3 ft. high and is perfectly hardy. It has creeping rootstocks and is easily increased by division in autumn or spring.

A. trinervius. — A beautiful species closely related to *A. sikkimensis*, and native of the Himalayas. It grows 2½-4 ft. high, and has lance-shaped coarsely toothed leaves 3-4 in. long. The white or pale bluish-purple flower-heads, over an inch across, are borne in loose clusters from August to October.

Culture &c. as above.

A. turbinellus. — A handsome plant 2-3 ft. high, with lance-shaped, somewhat stem-clasping ciliated leaves. Flowers in summer and autumn, delicate mauve.

Culture &c. as above.

A. umbellatus. — A tall-growing plant 5-8 ft. high, with masses of white flowers with yellow centres borne in autumn.

Culture &c. as above.

A. undulatus. — About 3 feet high, with hairy stems. Leaves oblong heart-shaped, stem-clasping, with winged stalks. Flowers in August, white, changing to purple.

Culture &c. as above.

A. versicolor. — A pretty, rather prostrate species 9-15 in. high, with smooth oblong lance-shaped, tapering leaves, lower ones serrate, stalked; upper ones sessile, stem-clasping. Flowers in September, 1 in. across, white to rose or lilac. The variety *Antigone* grows about 3½ ft. high, and is less bushy than the type.

Culture &c. as above.

A. vimineus. — A pretty bushy species, about 2½ ft. high, with narrow linear leaves. Flowers in September, white, ½ in. across, numerous. The variety *Cassiope* is somewhat taller, with white and lilac flowers; and *nanus* is dwarfer in habit.

Culture &c. as above.

OLEARIA (DAISY TREE). — A genus consisting of 85 species of arborescent shrubs or bushes, rarely herbs, with alternate or rarely opposite entire or toothed leaves. Flower heads solitary, corymbose or paniculate. Involucre ovoid, bell-shaped, or hemispherical. Disc flat or somewhat convex, pitted. Achenes smooth or slightly flattened. Pappus bristly.

Culture and Propagation. — It is practically useless to grow Olearias in cold bleak parts of the country, although *O. Haasti* is recorded as having been uninjured by 13° frost in the gardens of Alnwick Castle, Northumberland. The other species, however, have not been proved quite so hardy. They like rich loam, but do well in ordinary garden soil, and make good bushes for the border or shrubbery. To increase the plants, cuttings of the half-ripened young shoots 4-6 in. long should be inserted in sandy soil in a close cold frame, or handlight, and kept shaded until nearly rooted. Cuttings of the ripened shoots may be inserted in the same way about September, and by the following spring will be well rooted. Seeds of some of the Daisy Trees (e.g. *O. Haasti* and *O. macrodonta*) are ripened freely in our climate, and may be sown in cold frames when fully ripe, or in spring in gentle heat. The seedlings are to be pricked out when large enough, and may be grown on in cold frames until they have made sturdy little bushes. Plants raised from seeds ripened in the British Islands are far more likely to stand the severities of our winters than are those raised from imported seeds.

O. dentata. — An Australian shrub with elliptic or heart-shaped ovate crenate leaves 1½-2 in. long, and rosy-white flower heads about 1½ in. across with a bright yellow centre.

Culture &c. as above. Hardy only in the mildest parts of the kingdom.

O. Forsteri. — A New Zealand shrub with oblong blunt wavy leaves 2-3 in. long, downy white beneath. Flower-heads white, corymbose.

Culture &c. as above.

O. Haasti. — A pretty New Zealand shrub 2-4 ft. high, with hoary young shoots, ovate oblong or elliptic leaves about 1 in. long, white beneath and somewhat resembling those of the Box tree. Flowers in August, small, white, Daisy-

like, borne in hoary cymes in great profusion, literally covering the bushes.

Culture &c. as above.

O. insignis.—A beautiful New Zealand shrub, with thick leathery elliptic rounded leaves, 3-5 in. long, 2 in. broad, shining green above, covered with a pale brown woolly felt beneath, as are also the branches. Flowers large Daisy-like, 2 in. or more across, white, with a yellow centre, and borne on stalks 6-9 in. long. They last for a month or 6 weeks in perfection.

Culture &c. as above. This charming plant unfortunately is too tender for cultivation in the open air except in the very mildest parts of the south of England and Ireland, and parts of the south-west coast and islands of Scotland. If it could only be got to ripen seeds, it might be possible to raise plants with a hardier constitution in the course of time.

O. macrodonta.—A New Zealand shrub with elliptic coarsely toothed Holly-like leaves, which emit an agreeable musky scent when bruised. Flowers in June and July, Daisy-like, white, borne in large roundish heads.

Culture &c. as above. In the south of England and Ireland this species is perfectly hardy and flowers freely. It attains a height of only 3 or 4 feet, but in a wild state as much as 20 ft. It may be mentioned that another name for this plant is *O. dentata*, which must not, however, be confused with the plant under that name described above. A species called *O. ilicifolia* is very similar to *O. macrodonta*, but is a much smoother plant.

O. nitida.—A handsome compact-growing New Zealand shrub with ovate leathery leaves about 2 in. long, the under surface of which, as well as the young branches, are covered with a thick silvery-white down. The small white flowers, with a bright yellow centre, are produced in great profusion in August and September in crowded clusters.

Culture &c. as above. This has proved hardy in the south of Ireland.

O. nummularifolia.—A more or less clammy New Zealand shrub, 1-10 ft. high, with roundish oblong or obovate hard leathery leaves, shining green above, covered with white or yellowish down beneath. Flowers in July, white or

yellowish. Quite hardy in the south of Scotland.

Culture &c. as above.

O. ramulosa (*Eurybia ramulosa*).—A graceful Tasmanian bush, the leaves and branches of which are covered with a roughish down. The leaves are oblong linear, about $\frac{1}{2}$ in. long, woolly beneath, and crowded on the shoots. The white Daisy-like flowers are borne in great profusion in September and October in elegant arching sprays, which look very attractive.

Culture &c. as above.

O. stellulata (*Eurybia Gunniana*).—A handsome Tasmanian shrub 3-5 ft. high, with hoary branches and oblanceolate coarsely toothed leaves, hoary on the under surface. Flowers in September, $\frac{3}{4}$ in. across, white, in great profusion.

Culture &c. as above. Requires protection in winter in cold districts.

O. Traversi (*Eurybia Traversi*).—A handsome evergreen tree, native of Chatham Island, New Zealand, where it reaches a height of 30-35 ft. It has opposite (not alternate as in most species) leaves, more or less ovate lance-shaped in outline, about $2\frac{1}{2}$ in. long, quite entire, smooth shining green above, paler and silky beneath. The creamy white flowers are individually very small, but they are borne in clustered panicles in the axils of the leaves and at the ends of the shoots in great profusion late in summer.

Culture &c. as above. This species can be grown in the open air with any degree of success only in the mildest parts of the kingdom.

ERIGERON (FLEABANE).—A genus consisting of about 100 species of annual, biennial, or perennial herbs resembling the Starworts (*Aster*), from which they differ chiefly in having the ray florets in several series. The upper (or cauline) leaves are alternate, entire, toothed, or rarely incised or dissected. Ray florets violet or white, disc usually yellow. Involucre hemispherical or bell-shaped. Receptacle flat or slightly convex.

Culture and Propagation.—Only a few species are of any garden value. They thrive in somewhat moist garden soil and are readily increased by division of the roots in spring or early autumn. They may also be raised from seeds sown as soon as ripe in cold frames, or in

spring, afterwards transferring the seedlings to the open border when large enough. They are excellent plants for the rock garden, or in front of the herbaceous border, but to obtain the finest effects they should be grown in bold masses.

E. alpinus.—A pretty native hairy perennial, 9–12 in. high, suitable for rockeries. Leaves oblong lance-shaped below, linear oblong above. Flowers in July and August, $\frac{3}{4}$ in. across, purple, with a yellow centre. The variety *grandiflorus* is superior to the type.

Culture &c. as above.

E. aurantiacus.—A native of Turkestan 9–12 in. high. Leaves oblong entire, upper ones lance-shaped, sessile. Flowers in early and late summer, about 2 in. across, bright orange, solitary, on a stout erect peduncle.

Culture &c. as above. This species is remarkable for the bright orange-yellow of its flowers, so utterly distinct from other species of *Erigeron*. It may be increased by division, but not quite so rapidly as some others, and it is therefore advisable where a large stock is required to obtain plants from seeds also.

E. caucasicus.—A Caucasian perennial 9–12 in. high, with lower leaves spoon-shaped, upper ones strap-shaped, stem-clasping. Flowers in summer, about 1 in. across, rosy-pink, or purple, in loose masses on stems nearly 2 ft. high.

Culture &c. as above.

E. glabellus.—A N. American perennial 6–18 in. high. Leaves oblong lance-shaped, pointed above, spoon-shaped and stalked below. Flowers in June, light blue or purple, with a yellow centre.

Culture &c. as above.

E. glaucus.—A native of N.W. America 6–12 in. high, of creeping habit. Leaves oblong ovate or somewhat spoon-shaped, ciliated, glaucous, clammy, lower ones with winged stalks, upper ones sessile. Flowers in summer and autumn, lilac-purple.

Culture &c. as above. This is an evergreen species and retains its foliage during the winter months. It is easily increased by division.

E. grandiflorus.—A Rocky Mountain perennial 4–8 in. high. Lower leaves obovate spoon-shaped, upper ones oblong

to lance-shaped. Flowers late in summer, purple or whitish, rather large.

Culture &c. as above. This species makes fine evergreen masses of foliage, and may be used as a carpeting for taller plants. Easily increased by division.

E. mucronatus (*Vittadinia triloba*; *V. australis*).—A much-branched, spreading perennial 6–12 in. high, native of Australia and New Zealand. Leaves wedge-shaped or narrowly spoon-shaped, 3–5-lobed at the apex. Flowers during summer, ray florets white tipped with pink; disc florets yellow.

Culture &c. as above.

E. multiradiatus.—A pretty Himalayan plant 6–24 in. high, with oblong, toothed leaves tapering into a long stalk. Flowers in summer, about 2 in. across, purple with a yellow centre.

Culture &c. as above.

E. Roylei.—An ornamental species 4–8 in. high, with smooth, oblong spoon-shaped, ciliated leaves. Flowers in summer, 2 in. across, bluish-purple, with a yellow centre, borne in loose corymbs. This species is also a native of the Himalayas.

Culture &c. as above.

E. salsuginosus.—A pretty N. American perennial 12–18 in. high, with creeping rootstocks, and forming dense masses of foliage close to the ground. The soft mauve-tinted flowers with a yellow centre are about 3 in. across, appear in May and June, and are very effective when seen in bold masses.

Culture &c. as above.

E. speciosus (*Stenactis speciosa*). A showy N. American perennial about 2 ft. high. Lower leaves spoon-shaped, long-stalked; upper ones lance-shaped acute, sessile, 2–4 in. long. Flowers in summer, violet-purple, 2 in. or more across, in corymbose heads; centre yellow. The variety *superbus* is a larger and finer flower, approaching in appearance smaller forms of the typical *Callistephus hortensis* described at p. 499.

Culture &c. as above. This is the best known of all the *Erigerons*. It makes dense tufts close to the ground, and produces an immense number of blossoms. Easily increased by division.

Tribe IV. INULOIDEÆ.—Leaves usually alternate, entire, rarely opposite or lobed.

ANTENNARIA.—A genus of perennial herbs, closely related to *Gnaphalium*, and distinguished by the dry, coloured, chaffy scales around each head of tubular flowers, the stamens and pistils of which are on different plants (dioecious). Leaves clustered, entire.

Culture and Propagation.—The *Antennarias* are pretty plants, suitable for the rock garden, borders, or edgings. They thrive in light garden soil, and may be increased by division of the root in spring, or from seed sown at the same season in cold frames, or in the open border in April.

A. dioica (*Gnaphalium dioicum*).—*Cat's Foot.*—A British plant, found on heaths and sandy pastures, with procumbent shoots, and spoon-shaped or lance-shaped woolly leaves. Flowers in June, pink, in crowded corymbs 3–4 in. high. The variety *hyperborea* has more woolly leaves than the type; and *minima* is a small-growing form.

Culture &c. as above.

A. margaritacea (*Pearl Everlasting*). A native originally of N. America, but now found wild in parts of the British Islands and the Continent. It is about 1 ft. high, with linear lance-shaped acute leaves, downy white, especially beneath. Flowers in July and August, white, $\frac{1}{3}$ in. across, borne in corymbose clusters.

Culture &c. as above.

A. tomentosa (*A. candida*).—A dwarf silvery plant, considered to be a variety of *A. dioica*. It grows scarcely 1 in. high, and forms a dense carpet of silvery white in a short time, and is a favourite for edging, carpet-bedding, or for rockeries.

Culture &c. as above.

LEONTOPODIUM (LION'S FOOT; EDELWEISS).—A genus with 4 or 5 species of tufted woolly perennial herbs. Lower leaves rather spoon-shaped, upper ones alternate, entire. Flower-heads small, in dense cymes at the tips of the branches.

L. alpinum (*Gnaphalium Leontopodium*).—*Edelweiss.*—A pretty Swiss alpine plant 3–6 in. high, with white woolly leaves. Lower ones lance-shaped, narrowed into a stalk, upper ones sessile, linear oblong. Flowers in June and July, small, yellow, surrounded by an irregular rosette of densely woolly bracts.

Culture and Propagation.—The *Edelweiss* may be easily raised from seeds sown in slight heat about March. The plants grow well in exposed sunny spots in the rock garden or border, in rather sandy soil. Established plants may be divided annually, but it is easier and more satisfactory to raise them from seeds in the same way as recommended for annuals in general at p. 78.

GNAPHALIUM (CUD WEED; EVER-LASTING).—A genus containing about 100 species of annual, biennial, or perennial herbs, few of which are of any garden value. Leaves alternate, sessile, decurrent, or rarely stalked. Flower-heads small, sessile, often clustered, rarely in terminal corymbs. Bracts of the involucre scarious, often coloured at the tips.

G. lanatum.—A plant about 1 ft. high, chiefly valued for its beautiful silvery foliage, and much used for edging borders and beds.

Culture and Propagation.—This is practically the same as for *Antennaria* above. It thrives best on dry poor soils, and makes fine masses if pegged down. Easily increased by division in spring or early autumn.

OZOTHAMNUS.—A genus of shrubs or rarely herbs, closely related to *Helichrysum*. The flower-heads are small and often few-flowered. Involucre oblong ovoid or bell-shaped, the inner bracts usually tipped with a coloured point.

O. rosmarinifolius.—A beautiful fragrant shrub, native of Australia and Tasmania, where it attains a height of 6–10 ft. The branches are furnished with blunt linear Rosemary-like leaves, the edges of which are turned up or down. The small white flower-heads appear in July and August and are borne in great profusion in dense clusters.

Culture and Propagation.—This plant flourishes in ordinary good garden soil and is practically hardy in the southern and western parts of the kingdom. It should be planted in warm sunny positions, and may be increased by inserting cuttings of the half-ripened flowerless shoots in sandy soil about August under a handlight, keeping them shaded from the sun and sprinkled overhead occasionally.

WAITZIA.—A small genus of erect annuals (or perennials) with alternate

linear entire leaves, and flower-heads often borne in corymbose clusters. Involucre bell-shaped, hemispherical or roundish, yellow or white. Receptacle flat.

Culture and Propagation.—Waltzias flourish in ordinary garden soil in open sunny situations. They are all natives of Australia, where they are more or less of a perennial character. In our climate, however, it is easier to treat them as tender annuals and raise them from seeds sown in gentle heat about March, and plant the seedlings out at the end of May. They are good plants for the border, and their flowers when cut and dried in autumn may be kept for room decoration like other 'Everlasting' flowers, such as *Rhodanthe*, *Helichrysum* &c.

W. aurea.—A pretty species 12–18 in. high, with rosettes of linear leaves and shining golden flower-heads borne in loose clusters in summer and autumn.

Culture &c. as above.

W. corymbosa (*W. acuminata*).—A roughly hairy or downy plant 12–18 in. high, with stems branching from the middle upwards, clothed with linear leaves. Flowers satiny-white, rose, or yellow.

Culture &c. as above.

W. grandiflora.—This species resembles *W. aurea* in height, habit, and appearance, but produces much larger heads of bright yellow blossoms.

Culture &c. as above.

HELIPTERUM.—A genus closely allied to *Helichrysum*, from which it differs in having the hairs of the pappus plumose or feathery instead of roughly hairy.

Culture and Propagation.—Helipterums require rich soil and warm positions, otherwise they are hardly worth growing out of doors. Seeds may be sown outside in April, but are better raised in heat early in March. The seedlings are grown on until June, when they may be put outside in masses in the flower border. For the general treatment of annuals see p. 78.

H. humboldtianum (*H. Sandfordii*).—A pretty woolly-white West Australian annual 1–1½ ft. high, with lance-shaped linear leaves. Flowers in summer, bright yellow, passing into a metallic green when dry.

Culture &c. as above.

H. Manglesi (*Rhodanthe Manglesii*). A native of Western Australia 1–1½ ft. high, with ovate-oblong or broadly lance-shaped leaves, with rounded stem-clasping auricles at the base. Flowers in summer, soft rosy-pink with yellow centres, on long stalks.

Culture &c. as above.

H. roseum (*Acroclinium roseum*).—A pretty Australian annual 1–2 ft. high, with linear acute leaves and beautiful rosy flowers on the ends of the slender branches. When picked young the flower-heads may be dried as 'Everlastings.' There is a white variety *album*, and a large rose variety, *grandiflorum*.

Culture &c. as above.

HELICHRYSUM (EVERLASTING; IMMORTELLE).—A large genus containing 260 species of herbaceous or shrubby plants, mostly natives of S. Africa. Flower-heads large, solitary. Bracts of the involucre scarious, not silvery, spreading or recurved. Pappus rough or somewhat feathery.

Culture and Propagation.—The following are the only *Helichrysums* of note for the garden. They thrive in rich loamy soil, and should be grown in bold masses in the flower-border. Seeds are sown in slight heat in March, and are pricked out and grown on until June, when they can be put out in the same way as other annuals, see p. 78. Flowers for drying should only be half open, and hung downwards in bunches in a cool airy place to come to perfection.

H. arenarium (*Yellow Everlasting*).—A native of Europe 6–12 in. high, with lance-shaped entire, stem-clasping leaves, downy white on both surfaces. Flowers in summer, bright golden-yellow, borne in compound corymbs.

Culture &c. as above.

H. bracteatum.—A beautiful Australian annual 3–4 ft. high, with entire lance-shaped leaves, and variously coloured flowers in August. There are several fine varieties, with flowers varying in colour from pure white to rose, light and pale yellow. There are also handsome forms in which the central (or disc) florets have become changed from a tubular to a strap-shaped form, and this change has given a double-flowered race. The colouring among these double forms is very varied, and white, red, yellow, carmine,

purple and intermediate shades are to be met with. *H. acuminatum*, *H. chrysanthum*, and *H. macrocephalum* are mere forms of this species.

Culture &c. as above.

CASSINIA.—A genus containing about 20 species of shrubby plants having alternate entire leaves, the margins of which are often turned upwards, and the under surface often woolly. The small yellow flower-heads are borne in corymbs or panicles at the ends of the branches. Involucre narrowly ovoid or oblong with bracts in several rows. Receptacle flat or slightly convex.

C. fulvida (*Diplopappus chrysophyllus*).—*Golden Heath*.—A very distinct shrub 2–3 ft. high, native of New Zealand. The erect yellowish branches are furnished with short linear oblong Heath-like leaves which are deep green above and golden-yellow beneath, the margins being curled upwards, thus exposing in a conspicuous manner the colour of the under surface. The small yellow flower-heads appear in July and August, but are not particularly attractive although they add still further to the prevailing golden colour of the plant. From its small leaves and slender branches, and the general resemblance to the Heaths (see p. 580), it has been called the 'Golden Heath,' although as may be seen from its position in this work it has little in common with the plants of that genus.

Culture and Propagation.—This is the species best known in cultivation, although one or two others are to be met with occasionally in botanical collections. It flourishes in well-drained peat, and is practically hardy in most parts of the kingdom when placed in sheltered spots. It may be increased by means of cuttings of the half-ripened flowerless shoots, which should be inserted in very sandy peat and loam about August, and covered with a handlight or bell-glass until fairly well rooted. The cuttings must be shaded from sunshine and attention must be given to sprinkling overhead and ventilation as they begin to root. Seeds are ripened freely, and may be sown when ripe in cold frames in sandy peat and loam. When the seedlings have grown large enough they should be pricked out into a similar compost, and afterwards grown on in various sized pots until large and strong enough to be planted out of

doors—an operation best performed in mild weather in spring.

C. leptophylla (*Diplopappus leptophyllus*).—An attractive New Zealand shrub 2–3 ft. high, with grey and purplish stems covered with small fleshy green obovate leaves about $\frac{1}{4}$ in. long. The small white flowers are borne at the ends of the shoots in July, but are not very showy.

Culture &c. as above for *C. fulvida*.

C. Vauvilliersi.—This is also a native of New Zealand, and is a more vigorous and handsome plant than *C. leptophylla*. The yellowish branches are covered with obovate leaves about $\frac{1}{4}$ in. long, and the young shoots have a beautiful golden-tinted colour. Flowers as in *C. leptophylla*.

Culture &c. as above for *C. fulvida*.

PODOLEPIS.—A genus containing about a dozen species of more or less woolly annuals or perennials with alternate lance-shaped or linear, entire leaves, often stem-clasping at the base. Flower-heads with yellow, rosy, or violet ray-florets.

Culture and Propagation.—These are pretty plants for the border. They like a well-drained sandy soil and open sunny situations, as they are all natives of Australia. They may be raised from seeds annually in the same way as the Ammobiums, and also by sowing in the open border in April.

P. acuminata.—This grows about 18 in. high, and has lance-shaped stalked leaves, the lower ones stem-clasping. The yellow flower-heads appear in summer and autumn.

Culture &c. as above.

P. aristata (*P. chrysantha*).—This is very similar to *P. acuminata*, but is distinguished by the silkiness of the reddish involucre bracts. The leaves also are more pointed and glaucous beneath, and the beautiful golden-yellow flower-heads appear in summer and autumn.

Culture &c. as above.

P. gracilis.—A very pretty species about 18 in. high with reddish stems, sessile lance-shaped acute leaves, and beautiful rosy, lilac, or white flower-heads in summer and autumn.

Culture &c. as above.

AMMOBIUM.—A genus of hoary, woolly perennials, with alternate or clus-

tered entire leaves. Flowers yellow, in hemispherical heads. Receptacles convex. Pappus membranous-chaffy, shortly cup-shaped. Achenes angled, smooth or papillose.

A. alatum.—A beautiful Australian 'Everlasting,' 1½–2 ft. high, with winged stems. Leaves oblong lance-shaped; lower ones in tufted rosettes. Flowers from May to September, about 1 in. across, silvery white, with yellow centres; in loose, corymbose panicles. The variety *grandiflorum* has much larger and purer white flowers than the type, and comes true from seed.

Culture and Propagation.—This plant is best treated as a half-hardy annual or biennial, but in warm, sandy soil it becomes a perennial. Seeds may be sown in a cold frame in September, and the seedlings protected during the winter. Or they may be sown in slight heat about February or March, so as to be ready for the border about June. For the general treatment of annuals and biennials see p. 78.

INULA.—A genus containing less than 60 species of herbaceous perennials with radical or alternate, entire or serrate leaves. Flower-heads yellow; ray florets rarely white, strap-shaped, numerous; disc florets very numerous, tubular, hermaphrodite. Involucre hemispherical, with bracts spreading at the points. Receptacle flat or nearly so, pitted or honeycombed.

Culture and Propagation.—Inulas grow well in ordinary garden soil, and are easily increased in early autumn or spring by dividing the roots, or by seeds, the latter being sown either when ripe in cold frames or in spring in the open border if more plants are required than can be obtained by division. By cutting the roots into pieces about 2 in. long, and slightly covering them with light and rich sandy soil and placing in gentle heat during the winter or early spring months a good supply of plants can also be obtained. Being vigorous and somewhat coarse in growth, they are more suitable for wild or rough parts of the garden. The best results are obtained by good cultivation, and a good top-dressing of manure in autumn or winter is very beneficial.

I. glandulosa.—A hairy-stemmed Caucasian species, about 2 ft. high, with sessile, oblong, obscurely serrated leaves.

Flowers in July and August, orange-yellow, 4–6 in. across, with hairy involucre, and long narrow ray florets.

Culture &c. as above. This species does not seed freely in some localities, but it may be easily increased by division of the roots and also by root cuttings.

I. grandiflora.—This is a fine Himalayan perennial about 2 ft. high, and somewhat resembling *I. glandulosa*. The flower-heads appear in summer and are quite as large as those of *I. glandulosa*, and of a bright orange-yellow colour.

Culture &c. as above.

I. Helenium (Elecampene).—A strong-growing British perennial, 3–4 ft. high. Leaves oblong stalked below, ovate serrate wrinkled and sessile above. Flowers in summer, yellow, in large solitary heads about 3 in. across.

Culture &c. as above.

I. Hookeri.—A native of the Sikkim Himalayas 1–2 ft. high. Leaves 3–4 in. long, sessile or narrowed into short stalks, oblong lance-shaped, pointed, minutely toothed, hairy above, downy beneath. Flowers in September, pale yellow, in somewhat sweet-scented heads, 2½–3½ in. across; ray florets linear, 1 in. or more long; involucre broad, shaggy.

Culture &c. as above.

I. Oculus Christi.—An ornamental perennial 1½–2 ft. high, native of Eastern Europe. Leaves broadly lance-shaped, obtuse, entire or slightly toothed, rather downy. Flowers in summer, bright golden-yellow, 3½ in. or so across. Involucre very downy.

Culture &c. as above.

BUPHTHALMUM.—A genus containing 4 species of loosely branched, or tall, smooth, rough, or hairy perennials with alternate entire or toothed leaves. Flower-heads large, yellow, solitary at the ends of the stems. Receptacle convex. Achenes smooth.

Culture and Propagation.—Buphtalmums grow well in ordinary garden soil, and are easily increased by division of the roots in early spring or autumn. Seeds are ripened freely, and may be sown when ripe in cold frames, or in spring. The seedlings are pricked out and transferred to the open air when large enough. It is, however, scarcely necessary to increase the stock from seeds, as the plants are so easily divided.

B. grandiflorum.—A pretty Austrian plant 1½–2 ft. high, with alternate lance-shaped, slightly toothed, smooth leaves. Flowers from June to October, yellow, large; involucre naked.

Culture &c. as above. Grows well in shade.

B. salicifolium.—Also a native of Austria, 1½–2 ft. high. Leaves oblong-lance-shaped, somewhat serrated, hairy. Flowers in June, yellow, large, solitary.

Culture &c. as above.

Tribe V. HELIANTHOIDEÆ.—Leaves often opposite, rarely all alternate, entire, toothed, or variously cut. Disc florets usually yellow, rarely white, purplish or violet. Bracts of the involucre herbaceous, rarely dry and membranous.

SILPHIUM (ROSIN PLANT).—This genus includes 11 species of tall coarse perennial herbs with copious resinous juice. Leaves alternate, opposite, or whorled, entire, toothed or lobed. Flower-heads large, yellow, monœcious, in corymbose panicles. Ray florets female, disc florets sterile. Involucre broad and flattish, with bracts in many rows. Achenes smooth, flat, longitudinally winged; wings sometimes toothed or notched at the top.

Culture and Propagation.—These plants grow in any rough soil and are suitable for rough places in the garden in bold masses. They may be increased by division early in autumn or in spring. Seeds may also be sown when ripe in cold frames, and the seedlings transplanted to the open ground the following May, having been pricked out or thinned out at least once after germination. Seedling plants sometimes take 2 or 3 years to arrive at a really good blooming condition. Increase by dividing the roots is therefore to be preferred. All natives of N. America (United States).

S. laciniatum (*Compass Plant; Pilot Weed; Polar Plant*).—A vigorous perennial with stout stems 8 ft. or more high. Leaves pinnately parted, usually stalked and clasping at the base; segments lance-shaped, acute, cut-lobed or pinnatifid, rarely entire. Flowers in July, 1–2 in. across, yellow, forming racemose spikes.

The leaves of this plant are said to turn their faces due north and south on the open prairies—hence the popular names.

Culture &c. as above.

S. perfoliatum (*Cup Plant*).—A square-stemmed plant 4–8 ft. high, with

B. speciosum (*Telekia speciosa*).—A vigorous S. European perennial about 3 ft. high, with large, heart-shaped, coarsely toothed, bright green leaves 9–12 in. long, with long, channelled stalks. Flowers in July, deep orange-yellow, 4 in. across, with reddish-brown centres, very much resembling those of *Inula glandulosa*, only larger.

Culture &c. as above. This plant is seen to its best advantage in bold groups in open places.

entire ovate leaves 6–15 in. long, coarsely toothed, the upper ones united by their bases, forming a cup-like disc which holds a good deal of water when it rains; lower ones abruptly narrowed into winged stalks, connate at the base. Flowers in July, yellow, about 2 in. across.

Culture &c. as above.

S. terebinthinaceum (*Prairie Dock*). A smooth-stemmed species 4–10 ft. high, with ovate oblong, somewhat heart-shaped, toothed leaves, 1–2 ft. long, on slender stalks. Flowers from July to September, small, yellow. The variety *pinnatifidum* has deeply cut leaves.

Culture &c. as above.

S. trifoliatum.—This grows 4–6 ft. high, with rather smooth slender stems. Upper leaves lance-shaped, pointed, entire or slightly toothed, short-stalked, 3–4 in a whorl, or the highest opposite. Flowers in August, yellow, in loose panicles.

Culture &c. as above.

CHRYSOGONUM.—A small genus of herbs or shrubs with opposite, entire, toothed, or pinnately cut leaves, and yellow flower-heads.

C. virginianum.—A pretty N. American perennial 6–9 in. high, with ovate coarsely toothed leaves 1½–3 in. long, and yellow flower-heads in June, each one surrounded by 5 deep golden-yellow bracts of the involucre.

Culture and Propagation.—This is the only species out of half a dozen known in gardens. It looks well in bold masses in the rock garden or border, and flourishes in well-drained peat and loam in partially shaded and sheltered spots. It may be easily increased by dividing the tufts in spring as growth is commencing.

ZINNIA.—A genus containing about 12 species of annual or perennial herbs or sub-shrubs, with opposite or verticillate, sessile or stem-clasping entire leaves. Flower-heads solitary, stalked, at the tips or forks of the branches. Involucre bell-shaped, or somewhat cylindrical; bracts in 3 or more rows; receptacle conical or cylindrical. Ray florets strap-shaped; disc florets tubular, shortly 5-cleft. Achenes narrow, striped, smooth or hairy at the angles.

Culture and Propagation.—Zinnias when well grown are charming plants for the flower garden, in groups by themselves or massed with other plants. They like a rich loamy soil and sunny situations. Being mostly annuals they must be raised from seeds every year. About the middle of March is the best time to sow in gentle heat. It is a mistake to sow too early, as the plants become too weak and lanky before the planting-out time in June arrives. The seedlings should be pricked off when large enough to handle, and should be gradually hardened off in cooler and lightsome places. Both single and double varieties are worth growing, although the latter are somewhat dwarfier and more compact in habit.

The Zinnias are all natives of America—chiefly Mexico.

Z. elegans.—A hairy-stemmed annual 1½–2 ft. high, with heart-shaped, ovate, stem-clasping leaves, and flowers varying in colour from scarlet to crimson, rose, buff, or white.

From this species most of the garden Zinnias have been evolved by careful selection and hybridisation, and they possess some very fine colours, such as blood-red, orange-scarlet, rosy-carmine, deep yellow, vermilion &c. Among the named varieties may be mentioned: *coccinea*, scarlet; *Darwini*, with very double flowers; *flore pleno*, violacea, *gloriosa*. There are also miniature Pompon varieties about 6 in. high, suitable for edgings &c.

Culture &c. as above.

Z. haageana.—Similar in habit to *Z. elegans*, but with brilliant orange or yellow flower-heads. *Flore pleno* is a fine double-flowered variety; and *pumila flore pleno* is a dwarf kind about 6 in. high, with elegant double golden-yellow flowers striped with orange.

Other varieties known as *grandiflora*

and *zebrina* are choice garden forms, the latter having beautifully striped double flowers. Many other names will be found in catalogues, but a packet of good mixed seed will give all the colours desired. Other names for *Z. haageana* are *Z. mexicana* and *Z. aurea*.

Culture &c. as above.

Z. multiflora (*Z. verticillata*).—A bushy and rather hairy Mexican annual 1½–2 ft. high, with oval or oblong lance-shaped leaves. Flower-heads small, with deep red obovate rosy florets in the type. There is however a form with yellow florets.

Culture &c. as above. This species is not of great garden value, and with it may be classed *Z. pauciflora*, also a Mexican annual, with yellow flower-heads, having a deep dull red centre.

SANVITALIA.—A genus with a few species of annual or perennial herbs, having opposite entire leaves, and yellow or whitish flower-heads. Bracts of the involucre in 2–3 series. Receptacle flat or convex. Achenes smooth, those of the disc crowned with a pappus of 3 bristles.

S. procumbens.—A pretty Mexican annual with trailing branches and ovate entire leaves. Flowers in summer, like those of a small *Rudbeckia*, bright yellow, with a dark purplish disc. The double-flowered variety *flore pleno* is showier than the type, with wholly yellow flowers.

Culture and Propagation.—This is the only species in cultivation. Owing to its dwarf compact growth it looks well in masses at the edges of borders, or trailing over the sides of baskets. It thrives in sandy loam and peat, and seeds may be sown in autumn for spring flowering, or in March and April for late summer flowering. For the general treatment of annuals see p. 78.

HELIOPSIS.—A genus containing a few species of rather pretty annuals and perennials, with usually opposite stalked leaves (upper ones rarely alternate) and large yellow flower-heads. The annuals are rarely seen, and the perennials may be grown and increased as in the case of the perennial Sunflowers.

H. canescens (*Helianthus cordatus*). A bushy Peruvian annual 2–3 ft. high, with downy stems, and grey-green opposite heart-shaped acute leaves with coarsely

toothed margins. The yellow flower-heads, with a conical disc in the centre, appear from July to September, and are borne singly at the end of a long downy or hairy stalk which gradually becomes swollen towards the flower-head.

Culture and Propagation.—Being an annual this species may be treated as recommended for annuals in general at p. 78. The seeds should be sown in gentle heat in March, afterwards pricking the seedlings out, and by the end of May they will be fit for the open border. The plants may be placed 12–15 in. apart or more, and if grown in groups look very effective.

H. lævis.—A pretty free-growing perennial 3–6 ft. high, with ovate lance-shaped, coarsely toothed leaves, and flowers about 3 in. across in autumn on long stalks. The varieties *scabra* and *scabra major* are both improvements on the type, having larger and more numerous flowers. Native of N. America.

Culture and Propagation.—This species flourishes in ordinary good garden soil, but is well worth treating well. It makes a fine show in the herbaceous border if grown in fairly large clumps. Seeds are ripened freely, but it is much easier, and on the whole preferable, to increase the plants by dividing the roots in autumn or in spring, the latter season being generally regarded as best. The seeds may be sown in cold frames when ripe, or in spring, in light rich soil, and by the following autumn or spring, according to the period of sowing the seeds, the young plants may be transferred to the open ground about 15–18 in. apart.

GYMNOLOMIA (GYMNOPSIS).—A genus having about 16 species of erect branching more or less roughish hairy plants, with the lower leaves nearly all opposite, the upper ones nearly all alternate, entire, toothed, or lobed. Flower heads solitary or in loose clusters, yellow, or sometimes purple. Receptacle convex or conical. Ray florets spreading, entire, or slightly toothed at apex.

G. uniserialis.—A pretty Texan annual 1½–3 ft. high, with roughish hairy stems, and ovate elliptic coarsely toothed leaves reminding one of *Helianthus cucumerifolius*. The solitary flower-heads appear at the ends of the shoots from June to September, and are 2–3 in. across, having 5 broadly elliptic ray florets of a pretty

chrome yellow, surrounding a conical cluster of disc florets.

Culture and Propagation.—This recently introduced plant is ornamental grown in patches in the flower border, and will flourish in ordinary garden soil in sunny positions. It is raised from seeds sown in gentle heat in spring and planted out at the end of May, or seeds may be sown in the open border in April. It requires a little attention when young, as it is inclined to be 'miffy' or delicate until established. The flowers are excellent for cutting and last a long time.

MONTANOA.—A genus with over a dozen species of shrubs with opposite, entire, toothed or broadly-lobed leaves; lower ones often large and pinnately cut. Flower heads white or pink, in corymbose panicles. Ray florets sterile. Achenes smooth; the hypogynous disc sometimes much developed to resemble a cup-shaped pappus.

Culture and Propagation.—Montanoas are natives of Mexico, and are too tender even for the mildest parts of the British Islands, except during the summer months, when they are brought from the conservatory to lend an air of sub-tropical luxuriance to the garden. Seeds are sown in gentle bottom heat about March, and the seedlings are pricked out and gradually hardened off so as to be fit for planting out in June. In autumn the old plants may be taken into the greenhouse for winter. In January, if placed in heat, young shoots will spring from the roots, and may be used as cuttings in the same way as mentioned under *Dahlia* (p. 519). They will root in gentle heat in a close frame, and if afterwards potted up and grown on with plenty of light and air when established they make fine plants. The chief attraction of Montanoas consists in the large and attractively divided leaves, and not in the flower-heads.

M. bipinnatifida (*M. heracleifolia*; *Polymnia grandis*).—A striking plant 6–8 ft. high, with large opposite twice pinnately cut leaves with serrated segments, somewhat resembling those of *Heracleum* (p. 469). The stem and leaf-stalks are spotted with white, and the leaves when young are clothed with a soft whitish down. Flower-heads yellow.

Culture &c. as above.

M. mollissima.—An ornamental shrub with oval lance-shaped, sessile leaves, dull

green above, silvery white and hairy beneath. Flowers from August to October, white with a yellow centre.

Culture &c. as above.

M. tomentosa.—A shrub about 3 ft. high, with heart-shaped oblong-toothed woolly leaves, and white flowers in September in compound corymbs.

Culture &c. as above.

RUDBECKIA (CONE FLOWER).—A genus containing about 25 species of N. American perennials with alternate or rarely opposite, entire, toothed, incised, or pinnatisect leaves. Flower heads solitary or few, on long stalks; involucre hemispherical, the bracts in 2, 3, or 4 series; receptacle much elevated, cone-like or columnar; ray florets strap-shaped, spreading, often elongated, entire, or with 2-3 short teeth at the apex.

Culture and Propagation.—Rudbeckias grow well in ordinary garden soil, but the richer it is the better. Grown in masses the most showy kinds like *R. speciosa* and *R. maxima* are very fine. They may be increased by dividing the roots after flowering or in early spring. Also by seeds sown as soon as ripe in cold frames, or in gentle heat in spring, afterwards pricking the seedlings out and growing on until about the middle or end of May, when they may be planted in the open border. Seeds may also be sown out of doors in April and May, and the plants may be thinned out afterwards. The annual species of course can only be raised from seeds sown as above directed.

R. amplexicaulis (*Dracopis amplexicaulis*).—A bushy Mexican annual 1½-3 ft. high, with oval oblong stem-clasping leaves of a rather blue-green tint. The flower-heads are borne in great abundance during the summer and autumn months and consist of 6-8 ray florets surrounding a purple conical or cylindrical disc, which increases in length with age.

Culture &c. as above. Increased by seeds sown when ripe in cold frames; in spring in gentle heat, and in the open border in April and May.

R. bicolor.—This is a dwarf branching annual with bright yellow flowers and blackish-purple conical disc, borne from July to September. It requires to be sown in slight heat in February or March, and planted out in May or June.

Culture &c. as above. Increased by seed.

R. californica.—A vigorous Californian perennial 5-6 ft. high, with oval pointed roughish leaves, having an occasional lobe or tooth, the lower ones about 1 ft. long and 6 in. broad, narrowed into a stalk. Flowers in summer, golden-yellow, about 5 in. across, with a dark brown conical disc 2 in. or more high.

Culture &c. as above. Grows well in shade.

R. columnaris (*Lepachys columnaris*). A pretty N. American perennial 2-3 ft. high, with leaves pinnately cut into sharp-pointed linear lance-shaped segments. Flower-heads with broadly oblong elliptical drooping ray florets of a citron or orange-yellow colour, and a purplish cylindrical disc in the centre.

Culture &c. as above.

R. Drummondii.—A very handsome greyish-green downy plant, 1½-2 ft. high, native of Mexico. Leaves alternate, pinnate, with linear toothed segments; lower ones not so deeply cut. Flowers from June to September, yellow, with a large velvety blotch of purple-brown, and a brownish conical disc about 1 in. high. This species is sometimes called *Obeliscaria pulcherrima*. Although a perennial it is not quite hardy in northern parts, and in such localities is best raised from seeds annually as above directed.

Culture &c. as above.

R. fulgida (*R. chrysomela*).—A hairy species 2-3 ft. high, with oblong spoon-shaped or lance-shaped, stem-clasping 3-nerved leaves, lower ones toothed, upper entire. Flowers late in summer, 2-3 in. across, orange-yellow, with a dark purple conical disc.

Culture &c. as above.

R. grandiflora.—A pretty angular-stemmed species 3-4 ft. high. Lower leaves ovate crenate toothed; upper ones lance-shaped, roughish, obscurely crenate, all stalked. Flowers in September, 3-4 in. across, with a raised dark purple disc. Native of America.

Culture &c. as above.

R. hirta.—A very rough and bristly hairy plant 1-2 ft. high. Lower leaves spoon-shaped 3-nerved; upper ones oblong or lance-shaped, all sessile. Flowers from June to August 3-4 in. across, yellow, with a dark purple-brown disc.

Culture &c. as above. Will grow in shade.

R. laciniata.—A showy perennial 2-4 ft. high, the main stem sometimes reaching a height of 15 ft. and always needing support. Leaves roughish, deeply parted and cut, and clothed with small hairs, especially at the edges. Flowers in summer, clear yellow, 3-4 in. across, with a greenish-yellow conical disc. The variety *flore pleno* grows 6 ft. high, and has handsome double orange-yellow flowers.

Culture &c. as above.

R. maxima.—A fine species 4-8 ft. high, with oval or oblong, slightly toothed or entire glaucous leaves, stem-clasping above, stalked below, 8-12 in. long. Flowers in August, 3-4 in. across, yellow, with a cone-like disc; ray florets drooping.

Culture &c. as above.

R. pallida (*Echinacea angustifolia*). A pretty perennial 2-4 ft. high, with lance-shaped hairy leaves 4-6 in. long. Flowers in summer, 4-6 in. across, pale purple or rose.

Culture &c. as above.

R. pinnata (*Lepachys pinnatifida*).—A pretty plant about 3 ft. high, with pinnate leaves cut into 3-7 lance-shaped acute leaflets. Flowers in July, with light yellow drooping ray florets longer than the cylindrical disc.

Culture &c. as above.

R. purpurea (*Echinacea purpurea*).—A showy species 3-4 ft. high, with smooth stems, and roughish ovate lance-shaped leaves, tapering towards the base. Flowers in late summer and autumn, about 4 in. across, rosy-purple, solitary, on long, thick, rigid stalks. The variety *intermedia* has less drooping ray florets; and *serotina* is a later flowering hairy form. Native of Louisiana.

Culture &c. as above.

R. speciosa (*R. Newmanni*).—A handsome compact-growing species 2-3 ft. high. Lower leaves ovate, strongly ribbed, coarsely toothed, on slender stalks, 6-9 in. long; upper ones sessile lance-shaped. Flowers late in summer, 3-4 in. across, rich orange-yellow, with a velvety blackish-purple globose disc and drooping ray florets. Native of N. America.

Culture &c. as above.

R. triloba.—A vigorous hairy plant, 3-5 ft. high, with lower leaves 3-lobed and coarsely serrate; upper ones ovate lance-shaped, sessile; those springing from the root having slender stalks. Flowers in August, numerous, 2-3 in. across, yellow,

with a deep brown or blackish-purple disc. Native of Carolina.

Culture &c. as above.

HELIANTHUS (SUNFLOWER).—This genus (which now includes *Harpalum*) consists of about 50 species of tall annual or perennial herbs, mostly natives of N. America. Leaves large, simple, roughish. Flower-heads large, yellow; ray florets yellow; disc florets purple or violet.

Culture and Propagation.—All the Sunflowers are easily grown in ordinary garden soil, but the richer it is the better, as they are gross feeders. The annual kinds are easily raised from seeds sown in the open border. The perennial kinds are increased in autumn or spring by dividing the rootstocks, every shoot of which will produce a new plant. They like plenty of room to develop and an open sunny situation. In the late summer and autumn—from the beginning of August onwards—the perennial Sunflowers are very effective in masses by themselves either in borders or on the grass. If given plenty of space the stems will be strong enough to support themselves, but if too close together will become weak, straggling, and untidy unless neatly tied to stout stakes. Although the perennial Sunflowers grow well in our climate it is very rarely that any of them ripens seeds.

H. angustifolius (*Coreopsis angustifolia*; *Rudbeckia angustifolia*).—A native of wet places from New Jersey and Kentucky to Florida and Texas, 2-5 ft. high, with slender stems, and dark green narrow glossy leaves. Flowers in September and October, orange-yellow, over 2 in. across, with a blackish-purple centre.

Culture &c. as above. Increased by division.

H. annuus (*Common Sunflower*).—A well-known plant with stout stems 6-10 ft. high, and large heart-shaped, coarsely toothed leaves, the yellow flowers varying from 6 to 12 in. across. The common single variety is not worthy of cultivation in the flower garden, but some of the better kinds as *globosus*, *fistulosus*, *cucumerifolius*, *sulphureus*, *Dammani*, *californicus* *plenissimus* are more or less ornamental. *H. argophyllus* seems to be a form of the Common Sunflower, with soft silvery downy leaves, but it rarely attains a height of 6 ft. *H. lenticularis* is another variety about the same height.

Culture &c. as above. Raised from

seeds sown in the open border in April and May, or in slight heat in March, afterwards pricking the seedlings out, and transplanting in May.

H. decapetalus.—A pretty species, 4–6 ft. high, native of the banks of streams &c., from Canada to Georgia. Lower leaves rather ovate, pointed, about 6 in. long, the upper ones shorter, all somewhat obscurely toothed. Flowers 2–3 in. across, rich sulphur-yellow, with 12–14 ray florets.

Culture &c. as above. Increased by division.

H. divaricatus.—A native of the United States 4–6 ft. high, with green or purplish stems and ovate, pointed, stalked and opposite leaves. Flowers 2–3 in. or more across, orange-yellow.

Culture &c. as above. Increased by division.

H. doronicoides.—A native of Ohio to Missouri, 5–8 ft. high, with rough and densely downy stems. Leaves opposite (or alternate above), ovate, sessile, serrate, and tapering at both ends. Flowers late in autumn, yellow, crowded on short stalks.

Culture &c. as above. Increased by division.

H. exilis.—A slender-growing Californian annual 2–3 ft. high, with lance-shaped leaves and golden-yellow flowers about 2 in. across.

Culture &c. as above. Increased by division.

H. giganteus.—An elegant perennial, found in moist or swampy parts of Canada, Alabama, and Louisiana. Stems 10–12 ft. high, purplish, glaucous, bearing opposite lance-shaped stalked serrated leaves, the upper ones often with winged stalks. Flowers in autumn, deep yellow, 3–4 in. across, with a purplish centre.

Culture &c. as above. Increased by division.

H. grosse-serratus.—A very distinct species, native of dry places in the N. United States. Stems 6–9 ft. high, smooth and glaucous, with lance-shaped pointed, stalked leaves, coarsely toothed, deep green above, woolly beneath. Flowers late in autumn, 2–3 in. across, deep yellow.

Culture &c. as above. Increased by division.

H. lætiflorus.—A handsome species, native of Indiana, Illinois, and Wisconsin,

with stiff, roughly hairy stems, 6–8 ft. high. Upper leaves opposite or alternate, entire or coarsely toothed, lower leaves 9–12 in. long, broadly ovate acuminate stalked, 3-nerved. Flowers in autumn, 4–5 in. across, bright yellow, with a deeper yellow centre.

Culture &c. as above. This is one of the few perennial Sunflowers which ripens seeds in the British Islands.

H. lævigatus.—A native of the United States, 3–5 ft. high, with deep purple, smooth, and usually glaucous stems. Leaves all opposite (or the upper sometimes alternate) sessile or nearly so, lance-shaped acute, entire or slightly toothed, 3-nerved. Flowers bright yellow, 2–3 in. across, with 6–8 ray florets.

Culture &c. as above. Increased by division.

H. Maximiliani.—A native of the N. United States 7–8 ft. high, with roughish stems, and lance-shaped, pointed entire or slightly toothed leaves. Flowers in autumn, 3–4 in. across, golden-yellow.

Culture &c. as above. Increased by division.

H. mollis.—A hoary-looking plant 3–5 ft. high, with greyish-green, densely hairy stems. Leaves mostly opposite, ovate pointed, with a lobed or clasping base, serrate, softly hoary beneath. Flowers from July to October, golden-yellow, 4–5 in. across, with a darker centre.

Culture &c. as above. Increased by division.

H. multiflorus.—A beautiful plant 3–5 ft. high, with ovate heart-shaped, toothed leaves, and numerous bright yellow flowers, 3–5 in. across, from the end of July to October. The variety *maximus* is a taller plant with larger and finer flowers; *major* is similar; *Soleil d'or* and *Bouquet d'or* have double 'quilled' flowers; and *flore pleno* is a beautiful double-flowered form rather dwarfer than the type.

Culture &c. as above. Increased by division.

H. occidentalis.—A slender hairy-stemmed species 2–3 ft. high. Lower leaves ovate, obtuse or oblong, lance-shaped, rather leathery, 3-nerved, stalked. Flowers orange-yellow, 2–3 in. across, mostly solitary on long stalks.

Culture &c. as above. Increased by division.

H. orgyalis.—A species with smooth, purplish, glaucous stems 6-10 ft. high. Leaves alternate narrow and recurved, 5-8 in. or more long, entire or slightly toothed. Flowers late in autumn, numerous, about 2 in. across, deep golden-yellow, with a purple centre.

Culture &c. as above. Increased by division.

H. petiolaris.—A rather rare annual species, native of Texas, 2-3 ft. high, with hairy stems and leaves, and yellow flowers 3-4 in. across. The variety *canescens* is covered with a hoary down.

Culture &c. as above. Increased by seeds sown in the open border in April and May, or in gentle heat in March.

H. rigidus.—A well-known but very variable species 3-5 ft. high, with roughish or hairy purplish rigid stems, and broadly lance-shaped pointed 3-nerved leaves, alternate above, opposite below. Flowers from July to September, bright yellow, about 4 in. across, with a deep or dull purplish centre.

There are several varieties of this species all superior to the ordinary form. *Estivus*, *grandiflorus*, and *elegans* have purplish centres; *latifolius* has broad leaves and grows 6-7 ft. high. *Miss Mellish* is a very free strong-growing variety about the same height, with orange-yellow flowers 4-5 in. across, and one of the best kinds to grow for September blooming; *semiplenus* has numerous ray florets and a purplish disc.

Culture &c. as above. Increased by division.

H. scaberrimus.—A distinct Californian annual, with stout branching stems 2-3 ft. or more high, furnished with broad, oval, coarsely toothed leaves, and having large deep yellow flowers in summer.

Culture &c. as above. Increased by seeds sown in the open border in April and May, or in gentle heat in March.

ACTINOMERIS.—A small genus of perennial herbs with ovate or lance-shaped serrated leaves, and flowers in corymbose heads.

A. squarrosa (*Verbesina Coreopsis*).—A pretty N. American perennial with square, winged stems, about 3 ft. high. Leaves decurrent, broadly lance-shaped, coarsely toothed. Flowers in July and August, yellow, 2 in. or more across. The plants known as *alternifolius* and

helianthoides are forms of this, if not identical. There are two other species, both N. American, one *alata*, about 3 ft. high, the other *procera*, about 8 ft. high.

Culture and Propagation.—These ornamental plants grow well in loamy soil, and may be increased by dividing the roots in autumn or spring, or by seeds sown in the open border or in cold frames at the same periods.

VERBESINA (CROWN BEARD).—A genus containing about 50 species of more or less tender annual or perennial herbs, having opposite (or the upper alternate) leaves, stalked or sessile, toothed, lobed, or rarely entire. Flower-heads yellow, or the ray florets white, ligulate, spreading, entire or 2-3-toothed. Receptacle flat, convex or conical, with chaffy scales. Achenes flattened with two bristle-like awns.

Culture and Propagation.—These plants are sometimes used for outdoor effect, more for the appearance of the foliage than for the flowers. They thrive in rich soil, and may be raised from seeds sown in heat about March. The seedlings are pricked out into nice rich soil and gradually hardened off in cooler quarters so as to be ready for the open air about June. The perennials may be divided, or cuttings may be taken in spring, as with *Montanoas*, from the old rootstocks which have been placed in gentle heat and kept sprinkled every day. They nearly all require greenhouse shelter in winter.

V. alata.—A West Indian species, 2 ft. high, with nearly glabrous, wavy and sinuately toothed leaves, and orange-yellow flowers. It derives its specific name from the fact that the stems are winged.

Culture &c. as above.

V. encelioides.—A Mexican annual 2-3 ft. high, with ovate or oblong coarsely toothed leaves, having broadly winged stalks, lobed at the base, and yellow flowers in August.

Culture &c. as above.

V. gigantea.—A native of Jamaica, about 6½ ft. high, with beautiful large glistening green leaves with winged stalks, and yellow flowers in summer.

Culture &c. as above.

V. pinnatifida.—A bold Mexican perennial 3-4 ft. high, with broad deeply

lobed leaves, somewhat hairy on both surfaces, and 4-winged woolly stems. Flowers in August, pale yellow.

Culture &c. as above.

COREOPSIS (CALLIOPSIS).—TICK SEED.—A genus of smooth showy annual or perennial herbs, all natives of the United States. Leaves simple or pinnate, opposite. Ray florets spreading, more or less deeply toothed or notched at the apex. Bracts of the involucre in two rows, the outer spreading, the inner united at the base and erect. Receptacle with linear chaffy scales.

Culture and Propagation.—Coreopsis thrive in ordinary garden soil, and are among the showiest of summer flowers, especially when grown in masses. The annual kinds are easily raised from seeds sown in the open in April, or in slight heat early in March, afterwards pricking the seedlings out about the end of May. By sowing seeds of the annual varieties at intervals in the open border from April to the end of September a good succession of flowering plants can be obtained for six or seven months of the year. For the general treatment of hardy annuals see p. 78. The perennials may be raised in the same way or by cuttings during the summer, or by dividing the roots in autumn or spring. They are exceedingly effective grown in bold masses either in the flower border or rock garden, and their graceful flowering shoots are very valuable for cutting, as they last fresh a good time in water. The same may be said of the annual varieties.

C. aristosa.—An annual about 1-3 ft. high, with deeply pinnatifid leaves, having coarsely toothed, lance-shaped segments. Flowers in summer, orange-yellow, over 2 in. across, in terminal panicles.

Culture &c. as above recommended for the annual varieties.

C. atkinsoniana.—A graceful annual 2-4 ft. high, closely related to *C. Drummondii*, but with leaves cut into numerous linear lobes. The flowers are 1½-2 in. across, bright yellow, with a conspicuous reddish-purple blotch at the base of each ray floret.

Culture &c. as above recommended for the annual species.

C. aurea.—A smooth biennial 1-3 ft. high, with 3-7-parted leaves having lance-shaped segments. Flowers in autumn

about 2½ in. across, golden-yellow, with a dull yellow centre.

Culture &c. as above recommended for the annual species. Increased by sowing seeds at intervals from April to September in the open border.

C. auriculata.—A beautiful perennial 1½-2 ft. high, with entire or occasionally 3-lobed leaves. Flowers in summer on long stalks, usually solitary, yellow, with a band of purple-brown at the base of the ray florets.

Culture &c. as above.

C. cardaminifolia.—A beautiful dense-growing annual 1-2 ft. high with more or less deeply divided leaves, the lobes of the lower ones being oval or lance-shaped, and often very narrow and linear. The flowers appear in summer and autumn; they are of a pleasing soft yellow colour, and 1-2 in. across.

Culture &c. as above for *C. aurea*.

C. coronata.—A handsome annual about 2 ft. high, with opposite spoon-shaped leaves tapering at the base, entire or pinnately cut. Flowers in summer, orange, spotted with brownish-purple at the base, and 2-3 in. across.

Culture &c. as above.

C. Drummondii (C. diversifolia).—A beautiful annual 12-18 in. high, with pinnate leaves divided into ovate or lance-shaped lobes. Flowers in summer, bright yellow, 2 in. or more across, with a band of rich crimson-brown around the disc.

Culture &c. as above recommended for the annual species. This is one of the best known kinds and is a great favourite with cottagers in many parts of the kingdom.

C. grandiflora.—A splendid showy perennial 3 ft. high, the best of all. Leaves almost sessile, bearded at the base. Flowers bright self-yellow, 2-3 in. across, all through the summer months. Ray florets 5-toothed, deeply cut.

Culture &c. as above. A splendid plant for cutting.

C. japonica.—This is the only species of Coreopsis yet introduced from Japan, and is at present scarcely known. It has linear lance-shaped leaves, and heads of soft bright yellow flowers produced during the summer and autumn months.

Culture &c. as above.

C. lanceolata.—A fine perennial 1-3 ft. high, with entire bearded lance-shaped

leaves, upper ones slightly connate at the base. Flowers bright yellow, 2-3 in. across; ray florets 4-toothed.

Culture &c. as above. A splendid plant for cutting.

C. nudata.—A distinct-looking herbaceous perennial with Rush-like leaves. The flower-heads somewhat resemble those of a single Dahlia; they are 2½-3 in. across, purple in colour with a conspicuous yellow disc.

Culture &c. as above for the perennial kinds.

C. tinctoria (*C. bicolor*).—A pretty slender-growing annual, 1½-2 ft. high. Leaves pinnate with linear segments. Flowers bright yellow with a purple-brown blotch at the base of the jagged-toothed ray florets. There are several varieties, but *nana*, a dwarf-growing one, *atrosanguinea* with deep purplish flowers, and *nigra speciosa*, a dark brown self-coloured form, are perhaps best known.

Culture &c. as above recommended for the annual species. *C. tinctoria* and its varieties are even more popular than *C. Drummondii*.

C. verticillata (*C. tenuifolia*).—A pretty perennial with furrowed stems 1-2 ft. high, and leaves much divided into linear whorled segments. Flowers bright golden-yellow, about 1½ in. across.

Culture &c. as above for the perennial species.

LEPTOSYNE.—A genus closely related to *Coreopsis* and containing about 7 species of annual or perennial herbs or shrubs, with pinnately divided or dissected leaves, and showy heads of bright yellow flowers. They have the habit of *Coreopsis* but differ in having the ray florets pistillate (or female), and always with a ring of hairs on the tube or throat of the disc flowers.

Culture and Propagation.—This is practically the same as for *Coreopsis*, but they are more tender. The plants flourish in ordinary good garden soil, and look very effective grown in masses. They may be raised from seeds sown in the open border in April or in gentle heat in March, and the seedlings transplanted in May or June. The perennials may also be increased from seeds in the same way, as they are too tender to stand our winters.

L. callipsoidea.—A pretty Californian annual 1-2 ft. high, with narrow linear

lobed or incised leaves. Flowers in autumn, yellow, rather large, on long stalks.

Culture &c. as above. This species is also known in gardens as *L. maritima*, but it is quite distinct from the true plant of that name. Its flowers very much resemble those of a *Coreopsis* and are usually composed of 8 oblong wedge-shaped bluntly toothed ray florets surrounding the small disc.

L. Douglasi is a half-hardy annual about 1 ft. high with finely divided leaves and yellow flower-heads.

Culture &c. as above.

L. gigantea.—A vigorous-growing Californian annual with soft-wooded stems 2-8 ft. high, furnished with finely divided leaves. The yellow flower-heads appear in summer and autumn, and very much resemble those of a small Sunflower.

Culture &c. as above.

L. maritima (*Coreopsis maritima*).—A somewhat tender American perennial, 6-12 in. high, with leaves twice pinnately divided into narrow linear lobes. Flowers in autumn, yellow, 2-3 in. across, with 16-20 oblong ray florets surrounding a much deeper orange-yellow disc.

Culture &c. as above. Although a true perennial, *L. maritima* is rather too tender to stand our winters except perhaps in the very mildest parts. It is, therefore, best as a rule to treat it as a half-hardy annual, and raise the plants from seeds sown in gentle heat every spring, or in cold frames in autumn.

L. Stillmani.—A recently introduced Californian annual resembling *L. Douglasi*. It has graceful thinly cut foliage and grows about 1 ft. high, forming a compact bushy plant. Flowers golden-yellow, about 1½ in. across, borne at the tips of almost every shoot in summer.

Culture &c. as above. It is best to sow this species in the open border in sandy soil and sunny situations. It will often bloom four or five weeks afterwards.

DAHLIA.—A genus of beautiful and popular herbaceous plants distinguished botanically by having a double involucre, no pappus, and a large scarious bracteole at the base of each floret. The leaves are opposite, and once, twice, or thrice pinnately parted. Flower-heads large and borne on long stalks.

There are only about half a dozen

wild species, all natives of Mexico, and the first plant was introduced just over 100 years ago—in 1789—by the Marchioness of Bute. Owing to the ease with which it has been induced by cultivation to produce double flowers, the Dahlia has since that period undergone vast changes at the hands of the gardener, and there are now many varieties which may be roughly classified as follows:—

1. *Single Dahlias*.—These are the outcome of *D. coccinea* and *D. lutea*, and are recognised by having a disc of tubular florets, surrounded by the larger and more showy ray florets. For many years the single-flowered Dahlias were sadly neglected owing chiefly to the great strides that were made in raising new forms of the show, fancy, and other sections, with double flowers. Of late years, however, they have again come into favour, and it is not too much to say that in many ways they equal if they do not actually surpass the double forms in beauty and grace when well grown.

2. *Show Dahlias*.—These include all self-coloured double flowers, and all shaded or having the petals pale and edged with a distinct colour such as pink, purple, crimson, mauve &c.

3. *Fancy Dahlias*.—These have two or more colours, and may also have the petals striped or tipped. They are somewhat confused with the show varieties.

4. *Cactus or Decorative Dahlias*. These have arisen from *D. Juarezi*, which was not introduced until about 1872, and was first exhibited in London in September 1879, but attracted little attention. Since then, however, it has developed some of the finest Dahlias in cultivation—recognised by the more or less pointed starry, double flowers. What are known as 'Single' Cactus Dahlias have been produced of recent years.

5. *Bedding, Bouquet, or Pompon Dahlias*.—A section with small beautifully symmetrical double flowers. The plants are more dwarf and compact in growth than those of the other sections.

6. *Tom Thumb Dahlias*.—This is a very dwarf race, stunted in growth and not quite so free-flowering as the other sections.

The garden Dahlia on the whole seems to have been evolved by continually crossing and intercrossing the best forms of *D. coccinea*, *D. Merveille* and *D. variabilis*, and there is nothing

to prevent still further complications with the progress of time.

It would be useless to burden these pages with lists of the varieties in each class, for the simple reason that many, if not most of them, would be quite unknown in twelve months time. Suffice it to say that between 600 and 800 varieties have been considered distinct enough for naming, so far, and each year several new ones are added. In obtaining a collection, the best plan is to consult a good grower as to the best kinds required for any particular purpose, and in any special shade of colour. The catalogues published annually will be of great assistance. Always select plants that throw the flowers well above the foliage and do not hang their heads. When making a selection of Dahlias it is always the best plan to examine the varieties as they are naturally grown. It will then be easy to see those of vigorous habit and freedom of flowering. When seen at exhibitions the blossoms are naturally displayed to the best advantage to attract attention, and the most floppy flowers can be made to stand as erect as their more vigorous brethren.

Culture.—Dahlias like a rather rich, heavy loam, which should have been well manured and dug some time previous to planting. Except in the southern parts of England and Ireland perhaps, it is hardly safe to put the plants out until about the first or second week in June, according to locality and the season. The plants should not be nearer to each other than 4 or 5 feet. It looks a terrible waste of ground at first, but the growth of a month or two will show that in some cases at least it is barely sufficient.

Each plant should have a strong stout stake about 6 ft. high or more put to it when planted, thus avoiding injury to the roots later on.

With the advance of time, the strong shoots should be securely tied to the stake, and all weak growths removed, so as to give greater vigour to the remaining shoots and blossoms. During summer plenty of water should be given to the roots, and a good mulching of manure will tend to produce larger, finer, and clearer coloured blooms.

Position.—An aspect facing south or west is suitable, and if the beds can be protected from rough winds by hedges of other plants, so much the better.

Storing.—By October or as soon as the stems have been killed down by frosts, the tuberous roots should be dug up carefully, leaving about 6 in. of the old stems. The soil should be shaken away, the plants carefully labelled if it is desired to keep the varieties distinct, and then stored away in a dry cool airy place where they will be free from frost during the winter. They should be overhauled occasionally and any rotten portions cut away.

Propagation.—Dahlias are increased by dividing the tuberous roots, by cuttings, and by seeds. The latter are produced freely by the single varieties and may be sown in gentle heat about March. The seedlings may be put singly into small pots and grown on till June, when they may be transferred to the open border where they are intended to bloom. New varieties may be obtained in this way, but as with many other florists' flowers the great majority will not be an improvement on existing varieties.

Where novelties are not required, the plants may be quickly increased by cuttings as follows:—

The tubers are taken from their storage quarters and placed in a heat of 60°–70° Fahr., about February or March, slightly covered with soil, and gently syringed every day. Stout, sturdy shoots are soon produced, and each one of these may be detached with a sharp knife and inserted in a small pot with sandy soil. It will root in a few days, and may be gradually hardened off and grown on until planting-out time. Where cuttings are in abundance it will save time to put several of them into a shallow box or pan. In summer time the young side shoots will also root freely if treated in the same way.

In very rare cases Dahlias are grafted in winter, but probably more as an experiment than anything else. A shoot, taken from a plant grown in a greenhouse, is inserted into a slit made in a healthy tuber, and the stock and graft are firmly secured and covered with clay or wax. The whole is then potted up and kept in a close frame with a just sufficiently high temperature, 60°–70° Fahr., to assist the action of the sap. When the union is complete the plant may be given more light and air, and in the spring time cuttings may be secured from it and rooted as above described.

Insect Pests.—Wherever Dahlias grow earwigs are almost surely found. These insects are very mischievous. They eat out the young shoots, and also destroy the florets among which they nestle. Small pots with a little hay or moss are usually placed bottom upwards on the top of the stakes. The earwigs nest in these, and if examined frequently many may be caught and shaken into a bucket of boiling water. Hollow Hemlock, Broad Bean, or Elder stems closed at one end have also been suggested as good earwig traps.

The following is a list of the natural species of Dahlia. They are all natives of Mexico.

D. coccinea (*D. bidentifolia*; *Georgina Cervantesi*).—A plant 3–4 ft. high, with roughish pinnate leaves. Flowers in autumn, ray florets scarlet, disc yellow; outer bracts of involucre 5, reflexed.

Culture &c. as above. Seeds are ripened freely in our climate.

D. gracilis.—Grows 4–5 ft. high, distinct and graceful in habit, with smooth twice pinnate leaves, having ovate coarsely crenate leaflets. Flowers in summer and autumn, brilliant orange-scarlet.

Culture &c. as above. Seeds are ripened freely in our climate.

D. imperialis.—A remarkable plant 10–12 ft. high. It rarely flowers in the open air, but its large and beautiful leaves make it a desirable plant for the summer. It must be removed to a greenhouse by the end of September or October for flowering. Flowers white tinged with lilac, and streaked with blood-red at the base, drooping, bell-shaped, in large panicles.

Culture &c. as above. Seeds are ripened freely in our climate.

D. Juarezi.—A fine Dahlia about 3 ft. high, with brilliant scarlet overlapping florets, varying in length. See paragraph above on Cactus or Decorative Dahlias.

Culture &c. as above. Seeds are ripened freely in our climate.

D. Mercki (*D. glabrata*).—A beautiful plant 2–4 ft. high, with 3-lobed toothed leaves. Flowers in October, white and yellow or lilac and yellow, rather small. The variety *decaisneana* has pinnate leaves and purple flowers with a golden centre.

Culture &c. as above. Ripens seeds freely.

D. variabilis (*D. crocata*; *D. super-*

flua).—This is probably the plant first introduced. The typical species has scarlet or red ray florets and a yellow disc; but there is great variation in the colour, and this character seems to have descended in a remarkable degree to the garden Dahlia in which almost every shade except blue is to be found.

Culture &c. as above.

D. Zimapani (*Cosmos diversifolius*). *Black Dahlia*.—A tuberous-rooted Mexican perennial, 12–18 in. high, with a compact bushy habit, and deep green leaves, cut into 5–7 ovate entire or slightly toothed lobes. The deep violet or almost blackish-purple flowers appear from July to October, and are borne singly on long stalks, well above the foliage. The variety *atropurpurea* is much deeper in colour than the type.

Culture &c. as above.

THELESERMA.—A small genus of smooth herbs or shrubs with opposite leaves (or the upper ones alternate), linear, thread-like, and once or twice pinnately parted.

T. filifolium.—A pretty bushy plant about 2 ft. high, native of Texas, with bright green finely divided leaves, and large orange-yellow flower-heads produced in summer, with a conspicuous purple-brown blotch at the base of the broadly obovate ray florets. The plant known as *Cosmidium burridgeanum* is a hybrid between this species and *Coreopsis tinctoria*, and is intermediate between the two species.

Culture and Propagation.—These annuals flourish in light sandy soil, and may be raised from seeds sown in gentle heat in March or in the open border in April as recommended for *Cosmos bipinnatus* below. Seeds may also be sown in cold frames in autumn, and the seedlings transferred to the open border the following spring, when danger from frost is past.

COSMOS.—Annuals and perennials with pinnate leaves and solitary flower-heads. Receptacle with linear acute coloured bracteoles as long as or longer than the florets. Achenes angular, crowned with 3–4 rigid bristles.

Culture and Propagation.—These plants are easily raised from seeds sown in gentle heat in early spring, and pricked out and treated like other tender annuals,
